tributions are by no means few. The opinion we naturally form of that vast tract of country known as Siberia is based upon historical rather than physical knowledge. However black and repellent the former may be, whoever has read Atkinson's charming work descriptive of his wanderings from the Ural Mountains to the Amoor River, must have been compelled to modify his opinion, so far at least as regards the beauties of nature, and the grandeur of the scenery. In general appearance the *Adenophoras* have an erect habit of growth, the stems rising from a dense fleshy crown to a height of from 2 to 3 feet, a development much greater than that with which they are usually credited; but, in strong rich soil, they have attained with me a height of even 4 feet under exceptionally favourable circumstances. The upper half of the stems form a conical mass of flowers, individually small as compared with many of the *Campanulas*, but distributed with such regularity, and supported on slender, though, at the same time, rigid foot-stalks, interspersed with a few narrow bract-like leaves, giving a symmetry and regularity to the general group, such as are possessed by very few plants; each flower, with its long exserted style, is seen individually, and thus possesses its own individual beauty, besides which the whole is enhanced by a general elegance of contour and lightness of arrangement. In colour, amongst the score of species described, with about a dozen of which we are familiar in cultivation, blue predominates, varying from the fairly deep tint of *A. coronata* to the light and delicate coerulean hue of *A. liliifolia*, with all sorts of intermediate gradations. Possibly there may be a pure white form; but such I have not yet seen. So frequent, however, is the white associated with the blue amongst the old Bell-flowers, that I have no doubt it will appear some of these days as a seedling sport. To give a description of each of the species, seeing that their resemblance, viewed by the untutored eye of the ordinary cultivator, is so great, would be unnecessary; I will, therefore, merely enumerate half-a-dozen of the most distinct species—*Adenophora communis*, *A. coronata*, *A. liliifolia*, *A. Lamarckii*, *A. stylosa*, and *A. pereskiaefolia*. In these there occur slight variations in colour and size of flower, and also in the form of the radical leaves; the latter, however, being produced early in the spring, lose a large portion of their character before the season is sufficiently advanced for the full development of the floral axis, which takes place during the months of July and August. As I before stated, the thick fleshy roots of the *Adenophora* appear to revel in a strong rich loam, and rather to rejoice in a moderately damp sub-soil; they are impatient of removal, and should not be increased by division. Unlike the *Platycodons*, they produce their seeds freely; and, what is more, the seedlings reproduce very constantly the specific characteristics of the parent. The genus *Adenophora* should find a place in every choice selection of herbaceous plants, alike on account of the elegance of its habit, the chaste and beautiful appearance of its bell-like blossoms, and the time during which its blooming season lasts.

Botanic Gardens, Hull.

J. C. NIVEN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Common Iris (*I. germanica*).—The sword-shaped foliage of this plant, just now so fresh and green, apart from its great purple flowers produced later in the season, renders it well worth growing in town gardens, where so few other plants succeed. Clumps of this Iris look extremely well in out-door vases along with Irish Ivy during the early spring months, and it also makes fine masses planted in moist situations, or in shady borders.—J. C. L.

Hyacinth Roots.—Your correspondent who writes on Hyacinths does not seem to be aware that they make two distinct set of roots. The first to support the blossoming, which are thin and fine, and can be seen in the water until the bloom is nearly over; the second set then comes forward, thick and fleshy, to mature the bloom for the succeeding season. Then is the time, not to dry them up, but to place them within the reach of food and nutriment.—I. W.

Graceful Wormwoods (*Artemisia*).—*Artemisia gracilis* is one of the most elegant of plants, and well adapted for imparting a grace to borders and sub-tropical gardens. *A. argentea* and *A. judaica*, with their beautifully cut, graceful, silvery foliage, are no less attractive than *gracilis*, and, for dinner-table decoration, the three plants are most desirable when in a small state. They are easily raised from seed like half-hardy annuals.—P. B.

Rosa diversifolia.—M. Carrière invites the attention of Rose-growers to this very rare and interesting variety, which, up to the present, is hardly known outside of the precincts of some botanic gardens. In its general appearance, it resembles the common Bengal Rose, but its fine claret-red, or nearly violet flowers, and its peculiar leaves so far distinguish it from that species as to render it a subject deserving of some consideration at the hands of our most eminent Rose-growers and hybridisers.

THE FRUIT GARDEN.

THE MADRESFIELD COURT GRAPE.

THE efforts of raisers of new Grapes have been, for some time past, turned to the desirable object of obtaining a black Grape with a decidedly Muscat flavour, so as to be a fitting companion to the Muscat of Alexandria. The best type yet obtained in this way is the Madresfield Court Black Muscat, notwithstanding some have strongly denounced it. It would appear to be a natural course of events with all new Grapes that they should be at first loudly be-praised, and then as vigorously condemned, until they either drop out of cultivation, or are recognised as undoubted acquisitions. The former fate is the rule, the latter the exception. The Madresfield Court Black Muscat is now being recognised as an undoubted acquisition. If the bunch is not large, it is of a good table and exhibition size; the berries are long-oval in shape; it sets freely, and with a decided Muscat flavour, it combines an extraordinary lusciousness. Every Grape cultivator acknowledges it to be a fine-looking Grape, and to possess, in the main, all the characteristics of a fine variety, but many of them say it has a fatal tendency to crack just as it is becoming fully ripe. That this result has followed many attempts to cultivate it is, unquestionably, true, but, at the same time, it can be well done without cracking. I have this season seen the Madresfield Court Grape growing at three famous Grape-producing establishments, where ordinary hot-house treatment was applied to it, viz., at Syon House, at Gunnersbury Park, and at Heckfield. In each case magnificent development of berry, combined with high class flavour, was the result, and with only a very slight tendency to crack in one instance, and that, it would appear, was accounted for on ordinary grounds. One cultivator states that the tendency to crack is the result of improper cultivation. It would appear that it is when the berries are three-parts coloured that the cracking appears, and, therefore, it is at the colouring stage that airing is of the highest importance. His advice is to "air freely from the time the sun strikes the house in the morning until it goes off in the afternoon, leaving a few inches on all night. Avoid, by all means, a close, moist atmosphere for therein lies the cause of cracking. Maintain a pure, dry, warm air in the house, say 65° at night, and from 70° to 75° in the day. By so doing I do not think anyone will have cause to complain of this noble Grape; for, by the above treatment, we have had some fine examples of it here for the last few years." The greatest and the most striking success to be recorded in connection with the Madresfield Court Grape, is the manner in which it has shown itself when grown in a cool house at Chiswick. Against a north wall there is a lean-to orchard-house, constructed after a design of the Rev. J. Fountaine; this is a cold house, all the heat it gets being from the sun. In this house, Mr. Barron planted, some three or four years ago, three Vines—i.e., two Black Hamburgs and one Madresfield Court—to iron pillars along the house, about 3 feet from the front; a strong rod from each Vine is carried up the inside of the house, and one down towards the front, also; the back wall of the house, has, planted against it, Black Hamburg and Alicante. Here, the Madresfield Court is a grand cool-house Grape; it has borne a capital crop of nice bunches, the berries finely finished, and with a charming bloom, and without the slightest appearance of cracking. As compared with the Black Hamburg and Black Alicante growing in the same house, the Madresfield Court has decidedly the best of it; in fact, it was superior in flavour to the Muscat Hamburg growing in a neighbouring Vinery, and assisted by artificial heat. The only other Grape that has the Muscat flavour, that will ripen in a cool house, is the White Frontignan; but the Madresfield Court excels it in many respects. We have then in the Madresfield Court Black Muscat a Grape that can be grown in a cool house under quite ordinary treatment; and which, when so cultivated, possesses all the qualities of a first-class Grape.

R. D.

VINES ON THEIR OWN ROOTS BEST.

LET me first introduce the Mrs. Pince Grape, which, after five years' trial, worked on the Black Hamburg, has proved little short of a complete failure. During the time just mentioned, the diameter of the stem at its greatest circumference did not exceed that of a vigorous Vine two years old, and no amount of coaxing could induce increased action. In consequence of debility, the bunches and berries were constantly small, accompanied by a slight deficiency of bloom. In short, it was evident that the stock was unsuitable for this variety. Now for contrary results. Towards the end of last August I happened to be in Exeter, and paid a visit to Streatham Hall, where the gardener, Mr. Beddard, is a first-class Grape-grower. On entering the first house, planted principally with Mrs. Pince I was surprised

to find such a magnificent crop; the bunches were large, the berries of immense size, and the colour perfect. I said to Mr. Beddard, "You have certainly redeemed the character of this Grape from the repeated charges brought against it." He replied, "When rightly treated, it is not equalled by any late kind in cultivation." In this case it was growing on its own roots, I, therefore, at once, concluded that I was wrong in grafting it on the Black Hamburg. The Lady Downes Grapes, in the same house, were equally meritorious, and the same may be said of all the Grapes under his charge. On two occasions, and under identical circumstances, the Alicante worked on the Hamburg proved as great a failure as the Mrs. Pince. The bunches and berries were small and deficient of colour. As yet, sufficient time has not elapsed to enable me to offer a reliable statement of the White Lady Downes, but, from what I have seen of its character, I am by no means sanguine as to quality. On the same stock the Black variety is much improved, not more vigorous, but decidedly larger both in bunch and berry, and, I fancy, less subject to scorch. Whether grafted or grown on its own roots, I have never been able to manage the Madresfield Grape properly. I have never had any difficulty in producing large handsome bunches of it, and perfectly coloured; but just at the completion of the ripening process decay began, and soon destroyed the crop. The true Tokay, under most conditions, is a rampant grower, but I find, when grafted, it keeps badly, even when the roots are confined to the interior of the house. The West's St. Peter's is greatly benefited by being grafted, which increases both the size of the bunch and berry; but when worked on the Barbarossa it deteriorates. I am beginning to be convinced that, except in very few cases, such as Snow's Muscat and some of the more delicate varieties of the Frontignans, the Grape Vine will always prove more satisfactory when cultivated on its own roots, than when grafted.

ALEXANDER CRAMB, in the Gardener.

CHANGING DWARF PEARS TO STANDARDS.

WE observe that some recommend planting deep, or banking up the soil around dwarf Pears, for the purpose of converting

a. Trunk of dwarf Pear tree. b. Pear stock inserted into it for new bottom. c. Cut for receiving the Pear stock. d. Pear stock, cut sloping before insertion.

them into standards by the emission of new roots from the Pear stem above the place of junction between Pear and Quince. The difficulty is, they are apt to send out a very few Pear roots, often only on one side, which tend to push the tree over, and they are rarely as perfect as with a full spread of roots on every side. A better mode, and one attended with but little labour, is to set two, three, or four thrifty seedling Pear trees, a year or two old, on opposite sides, close to the trunk of the bearing dwarf tree; when established one year, cut off the tops in wedge form, and slip them in under slits cut in the stem of the dwarf, as shown in the annexed figures. This should be done as soon as the bark begins to peel in the dwarf tree, when the points of the young Pear trees may be easily inserted. Grafting wax may be then applied, and the work is done. Usually, two Pear seedlings, or one on each side of the tree, are enough, giving, in a few years, two stout legs to the bearing tree, that brace it firmly, and in a few years more make one flat trunk. If three seedlings are used, they form a tripod, and if four, a four-sided stem.—*Cultivator*.

Vines for a Hamburg House.—At page 92, "G. S. D." makes inquiries about Vines for a Hamburg house. For the three best suitable white kinds I would recommend him to plant Duke of Buccleuch, Buckland's Sweetwater, and Royal Muscadine, all well-tried varieties, which are sure to give satisfaction under the most

ordinary treatment. For black sorts, I would plant Black Hamburg, Black Prince, and Barbarossa (Gros Guillaume), at the warmest end of the house. It is remarkable that black kinds, suitable as companions for the Hamburg, are very scarce. Apart from the whites enumerated, there are Golden Champion, Foster's White Seedling, Golden Hamburg, Duchess of Buccleuch, White Frontignan, Chasselas Musqué, Napoleon, Syrian, Trebbiano, &c., all adapted for a Hamburg house; while of blacks (with the exception of the varieties of Hamburgs), I could not select four equally good and suitable neighbours. A Hamburg house is the best place for the Duke of Buccleuch. Had I a Hamburg house to plant now, I would not trouble myself about variety, but would have the one-half Black Hamburg and the other half Duke of Buccleuch.—J. M.

THE LIBRARY.

FLORE DES SERRES.*

AFTER a more or less impatient waiting of nine or ten months, the subscribers to this interesting and beautiful, but most irregularly published work, have at last been gratified by the publication, on the first day of this month, of an unusually rich and abundant instalment, consisting of half a volume, contained in two thick triple parts, each of which is enriched with twenty-eight beautifully coloured plates, some of them of great horticultural interest, and most of them exceedingly true to nature, and exact and accurate representations of the plants and flowers which they profess to portray. These we may now proceed to examine cursorily and *seriatim*:—Plate 1. "Leucojum," or "Acis autumnalis." This is an exceedingly pretty little white bell-flowered gem, with grassy foliage, and blossoms closely resembling in shape those of the little Campanula pulla, of a pure white, the base of the bell, where the stalk joins it, being of a delicate rosy tint, and the flowers usually coming in pairs at the end of slight and gracefully-drooping flower-stalks, from 3 to 4 inches in height. This pretty little plant is perfectly hardy, and comes from the shores of the Mediterranean.—Plate 2. "Umbilicus spinosus." This, which is also known under the names of Crassula spinosa, Cotyledon spinosum, Sedum spinosum, Orostachys chlorantha, and Sempervivum cuspidatum, is a very ornamental and dwarf-growing species of the Crassula family, reproducing itself most freely in the shape of offsets, or young plants, thrown off from the root, and coming up all round the parent plant. This plant is found in Siberia, and also in both China and Japan. It will thrive well in the open ground during the summer, but must be lifted at the end of autumn, and wintered in a pot, as most of this family have to be in this changeable climate.—Plate 3. "Dolichos bicontortus." This singular leguminous plant, from Japan, is said to be quite hardy, and to produce large Pea-shaped blossoms, the outside petals of which, before the flower opens, are yellow, veined with black; but, when the flower opens, the inside colour is violet and white, making quite a pretty flower. But the curious parts of the plant are the seed-pods, produced in pairs on the top of long stems, and curling themselves round exactly like rams' horns; hence the name of "bicontortus," presenting a most singular and unique appearance. The plant, when grown at Bordeaux, reached a height of about 6 feet 6 inches. The flowers, however, are, unfortunately, extremely short-lived and can only be seen in beauty by early risers, as they expand at daybreak, and close their petals about 9 a.m. It is probably used as a vegetable in Japan.—Plate 4. "Amygdalus persicæfolius ruber," an ornamental-foliaged variety of the Peach, raised from seed in America. Its leaves are of a bright rosy-claret underneath, a colour which also pervades the stems of the young growth. The fruit is also said to be of excellent quality, and entirely red-fleshed, and the leaves are said to be never affected by the disease which commonly attacks Peach foliage, and which the French call La Cloque, but which has apparently no equivalent in the English language.—Plate 5. "Zea Mais, varieties Reuteri and erythrosperma," pretty deep red and golden-yellow ornamental varieties of the Indian Corn or Maize.—Plate 6. "Solanum ciliatum." This handsome bright scarlet-fruited annual variety of Solanum, from the Brazils, produces clusters of ornamental fruit in great abundance, each fruit about the size of a small Plum, and possessing the merit of not shrivelling as the season advances, but maintaining their round and plump appearance for nine or ten months. This variety was sent out a year or two since by Messrs. Carter & Co., of Holborn.—Plate 7. "Dicksonia antarctica at home." This is a representation of a large group of these magnificent Tree-Ferns as seen in their native habitat in the ravines of Tasmania, during a snowstorm.—Plate 8. "Hybrid Grape, Pearson's Ferdinand de Lesseps." This produces fruit of a bright golden colour and medium size, and of excellent quality and flavour. It is a cross between the Chasselas de Fontainebleau and an

* "Flore des Serres et Jardins de l'Europe." Completion of Volume XIX. Van Houtte, Ghent.

American variety known as the Strawberry Grape, and was raised by Mr. Pearson, of Chilwell.—Plate 9. "*Hyophorbe indica*, or *Areca butescens*." A graceful-foliaged cool greenhouse Palm, from the Mauritius and Isle of Bourbon.—Plate 10. "*Gladiolus purpureo auratus*." This is a much too highly-coloured representation of this species, which, instead of being the bright gold colour as painted in this plate, is, in reality, only a dull pale straw colour, only worth growing as a curiosity or in a collection of *Gladioli*, and by no means an ornamental variety.—Plate 11. "*Gladiolus Colvilli* and *Colvilli alba*." Faithful and accurate representations of these well-known, but too little cultivated, garden varieties of this beautiful and most ornamental autumn-blooming flower. Plate 12. "*Dahlia vert*." A curious variety of this well-known flower, raised by Herr Sieckmann, producing medium-sized fully double flowers of a bright clear green.—Plate 13. "*Lilium tigrinum flore pleno*." A beautiful fully double form of the common Tiger Lily, to which this plate hardly does justice, as the flower is, in reality, more double than it is there represented. This variety is perfectly hardy, and reproduces itself most freely by bulblets formed at the axils of all the leaves up the greater part of the flower-stem.—Plate 14. "*Cypripedium superbien*." A fine, bold, large-flowered variety of the Slipper plant, from Assam. This variety has been already figured in the 16th volume of this work, page 161; but the portrait there given was executed by a negligent artist from an almost faded flower, and gives no true idea of the beauty of the variety.—Plate 15. "*Kæmpferia Roscoeana*." A beautifully mottled-leaved foliage-plant from the East Indies, which requires the temperature of a stove.—Plates 16 and 17. "*Rhododendron hybridum nigrescens*." A double-page picture of one of Mr. Anthony Waterer's fine seedlings, all of which are quite hardy. This one is said to be extremely free-flowering, and is, as its name implies, of a shade of colour very nearly approaching black. These plates are not so well or so carefully executed as usual, and, I should think, hardly do justice to the variety.—Plate 18. "*Cocos Weddelliana*." This is, perhaps, the most elegant and graceful-growing of all cool greenhouse Palms, making a most beautiful pot-plant for table decoration, when in a small state, from its elegant feathering foliage.—Plate 19. "*Camellia japonica Etoile polaire*." An exceedingly pretty variety of this well-known plant, with striped rose and white flowers, sent out by Messrs. Henderson.—Plate 20. "*Wistaria multijuga*." A new and ornamental variety of this well-known wall plant, producing immensely long racemes of handsome Pea-shaped blossoms, the upper petals of which are lilac-blush and the lower ones deep purple. It was introduced from Japan by Von Siebold, of Leyden, and is perfectly hardy and marvellously quick growing, producing shoots of 13 feet in length in a single year, and most free-flowering, its flower racemes attaining twice the length figured in this plate, or over 18 inches; altogether, a most desirable addition to any collection of hardy climbing plants.—Plate 21. "*Echeveria agavoides*." This is a thick and solid-leaved variety of the House Leek, introduced from Mexico into French gardens, and already used by a hybridiser there (Mon. Deleuil) as one of the parents of his new hybrid *Echeveria scaphiphylla*.—Plates 22, 23. "*Azalea indica*," "Mrs. Wright." A beautiful seedling variety of this lovely flower, raised by M. Van Houtte, producing large semi-double flowers of a pure white, heavily and regularly streaked and spotted with bright carmine, and with a slight greenish-yellow shading towards the centre of the flower.—Plates 24, 25. "*Azalea indica*," "Madlle. Louise de Kerchove." A most lovely semi-double variety, also raised from seed by M. Van Houtte; no description of colours can do anything like justice to this exquisite variety, which must be seen in order to be fully appreciated.—Plates 26, 27. "*Azalea indica*," "Cocarde Orange." A charming semi-double variety of medium-sized flowers, of the most fiery orange-scarlet, with lighter crimson centre, reminding one of Madame Iris Lefebvre, but an improvement in clearness of colour on that fine variety. Mons. Van Coppenolle, of Ghent, is the fortunate raiser of this fine novelty, which was awarded the first prize for seedlings at Brussels when shown there last summer.—Plates 28, 29. "*Azalea indica*," "Sigismond Rucker." This magnificent single variety is, perhaps, the very finest for individual size of bloom of the many fine novelties raised and sent out by M. Van Houtte, of Ghent. Its flowers, of immense size, are mainly of a clear rosy-crimson colour, richly and evenly spotted on the upper petals with deep carmine, the whole flower being evenly and regularly bordered with an indented edging of pure white; altogether, a really first-class variety, which has already been seen and appreciated in London, having been awarded a first-class certificate by the Floral Committee of the Royal Horticultural Society when submitted to its notice during the season of 1873.

This notice concludes the first half of the present instalment of this work. The plates contained in the remaining triple part will be noticed and commented on in a future number. W. E. G.

Junior Carlton Club.

PENNY HILL, NEAR BAGSHOT.

THIS is one of the far from common gardens in which the most essential elements of garden scenery, trees, receive something like the attention which they deserve. Our attention was first directed to it by Mr. John Waterer, of Bagshot, who informed us that it contained some of the finest specimens of our rarer Pines. A recent visit made to the gardens showed this to be the case. The garden, which occupies a somewhat elevated and varied position near Bagshot, has not been long formed, and, therefore, old specimens of the common trees are not particularly noticeable; but, among the newer introductions, there are remarkably fine examples, and instructive to the tree-lover, as furnishing evidence of the value of some of the recent introductions. One of the foremost among these is the Albert Spruce (*Abies Alberti*), which we figure herewith, from a photograph taken by Mr. Vernon Heath, of Piccadilly. Some suppose this Spruce to be not very distinct from the Hemlock Spruce (*Abies canadensis*), and this may be so from a botanical point of view; but, judging from the fine and rapidly growing specimen at Penny Hill, we should say that they are essentially distinct in habit. No Pine or *Abies* throws up a freer or more graceful "leader" than this does, whereas the Hemlock is usually, in Britain, a low round-headed tree, which, from some unknown cause, does not thrive at all so well here as in its native country. There are two trees of the Albert Spruce at Penny Hill, one 25 and the other nearly 30 feet high, each as exquisitely graceful as the fairest young Deodar that graces an English lawn. Therefore, this tree may be assumed to be one of the most valuable for ornamental purposes, at least, that we have yet introduced. The remarkable Japanese Umbrella Pine is also in fine condition here, the largest specimen being 8 feet high by 6 feet in diameter, and in the most vigorous health. We have seen specimens as high, but not nearly so stoutly-formed and compact; Mr. Bohn's capital examples at Twickenham being quite open and slender, compared to Mr. Hodges's superb specimen. This is as dense as a compactly-clipped Box bush. After the *Araucaria*, it is the most distinct in aspect of all Conifers that will endure our climate, and will prove a more valuable acquisition than was at first expected. Its complete hardiness is greatly in its favour. There are many fine specimens of such plants as the *Libocedrus decurrens*, *Nordmanniana* Pine, the Giant Thuja (*Thuja gigantea*, commonly called T. Lobbi), *Cupressus nutkaensis*, &c.; but we are more interested in the remarkably striking specimens of the *Retinospora*, which here flourish so as to remind us of their tree-like character. *Retinospora pisifera* (true) is 15 feet high, and 14 feet through—a plummy mass of healthy deep-green shoots, each with all the grace of a Fern. There are various examples of *Thujopsis dolabrata variegata*, about 7 feet high, and in rude health, as are all the finer and newer kinds of *Abies* from Western America. Rarer still to see, however, is a specimen of the fine *Thujopsis Standishi*, 10 feet high, and in stout health. Although our present notice mainly concerns some of the rarer trees, we would like, in conclusion, to call attention to a very charming feature—an American garden on the model of that in the Botanic Gardens, Regent's Park, designed originally by Mr. Marnock, and long embellished by American plants from the Bagshot Nurseries. The American garden at Penny Hill occupies a hollow; it is, of course, permanently planted, and never covered over, so that it is only in the disposition of the ground that it can be said to resemble the Regent's Park arrangement. It was a good idea to imitate the pleasant diversity of the "Park" show, with its small clumps and isolated specimens as well as large masses, and, we should say, there are few prettier effects than that afforded by the American garden at Penny Hill, as seen from the rising ground around, when the bushes are in bloom. Some of the neatest and, in every way, the best Holly hedges we have seen occur at Penny Hill, and that to the collective extent of over three miles in length. These were all planted originally on the level ground, and there is much evidence in favour of this mode of planting instead of the ordinary one of planting on a slightly raised ledge. A peculiar aspect is imparted to various parts of the grounds by tall narrowly-pyramidal variegated Hollies; which are very strikingly associated with the green tapering Conifers.

THE ALBERT SPRUCE IN THE GARDENS AT PENNY HILL.

SOILS AND FERTILISERS.

USES OF LIME.

LIME, when applied to the soil, says the *Irish Farmers' Gazette*, acts in a two-fold manner. It acts physically by altering the mechanical condition of the soil, imparting friability to stiff soils and firmness to loose soils. It acts chemically by decomposing acid compounds existing in the soil, and in this manner it forms new and wholesome compounds out of others which were injurious to vegetation. It exercises a powerful influence upon inert organic matter; brings it into a state of active decomposition, and thus renders it fit for the support of other and more valuable forms of vegetation than it could have sustained in its natural state. Lime also acts on a variety of other substances, and sets them free to perform their office as part of the food of plants. It also forms a considerable proportion of the inorganic matter of many plants, so that it feeds them both directly and indirectly.

Quicklime.

Limestone is a carbonate of lime, more or less pure, and, if crushed into a fine powder, it may be applied to the soil in that state. The usual mode of preparation, however, is to burn the limestone in a kiln, specially constructed for the purpose; and the effect of this process is to drive off the carbonic acid which existed in the stone previous to its being put into the kiln. Freshly-burned limestone becomes caustic lime or quicklime; but if the burned lime is left exposed to the air for a sufficient length of time, it will re-absorb carbonic acid from the air; and, when this is the case, it becomes mild lime. It is in one or other of these states—either in its caustic or in its mild state—that lime is applied to the land. Both kinds ultimately produce the same effects, the great point in which they differ being the comparative rapidity with which they act. Caustic or quicklime has a speedy action on matter; while that of mild lime or carbonate of lime is not so immediately apparent. Limestone-gravel, shell-marl, and shell-sand are examples of carbonate of lime; and these produce a marked effect upon land and upon herbage, when judiciously applied. Lime, when brought from the kiln, is usually put down upon the land to which it is to be applied in small heaps, at regular distances; and, if allowed to remain for a considerable time, will gradually absorb sufficient moisture from the atmosphere to slake it. The heaps are then spread over the surface, and, in doing so, due care should be taken that the bottom of the heap is well cleared out. Lime is also sometimes laid down in a large long heap, and then slaked by pouring water over it. The value of lime depends upon the soil being rich in vegetable matters, or upon its containing plenty of mineral food.

Lime Composts.

Another and important mode of applying lime is in the form of a compost, with earth or vegetable matter. In forming a heap of this kind, first lay down a layer of earth, &c., fully a foot thick; then spread on this bed a layer of quicklime, at the rate of two bushels—that is, half a barrel—to the cubic yard of stuff. A layer of stuff is next laid down over the lime, and lime over it, and so on, until three or four layers of stuff and of lime have been laid, the upper layer of all being one of lime, slightly covered with earth. We have occasionally sprinkled a little coarse salt amongst each layer of stuff, and have had reason to believe that the addition was of service. The heap should remain untouched for three or four weeks, after which it should be turned over, beginning at one end, and carefully mixing the lime and soil together. If any part of the heap appears poor, a shovelful or two of lime may be thrown in at that spot. Another interval must elapse before the heap is again touched, and, when it is to be turned the second time, the operation should commence at the opposite end to that where it was begun at the first turning. This second turning will incorporate the materials, and, after a short time, the compost may be put on the land; at the same time, the longer it can remain, it will be all the better. We have had compost heaps lying nearly twelve months before the materials were spread upon the land. In preparing a compost, the nature of the land to which it is to be applied should be taken into account, so as to effect that intermixture of soils which is frequently productive of much advantage. A compost should not be formed of quicklime and decomposed or fermenting farm-yard dung, because the quicklime expels the ammonia from manure which is in a state of fermentation.

Quantity to Apply.

The quantity of lime that may be applied at a time varies with the nature of the soil; heavy clay soil requiring the largest quantity. Usually the quantity applied ranges from twenty to fifty barrels to the acre; but a less quantity will do.

THE KITCHEN GARDEN.

CULTURE OF THE ONION.

THE best soil to grow Onions in is a rich, deep, strong, and loamy one, and the best manure is deodorised night soil mixed with pigeon or fowl dung. The beds should be marked out early in November, and laid up in rough ridges so as to expose the soil to frost. If large Onions are wanted, some guano should be sprinkled on the bed in February. This should be raked in, and in a fortnight afterwards the seed may be sown. Where guano is used, the seed ought never to be put in before a fortnight's time has elapsed, otherwise the guano will kill the seed; but after a fortnight it is safe to sow it.

Sowing and Thinning.

In large gardens or allotments the seed is best sown in drills from 6 to 8 inches wide. On this system the plants not only get more air, but they are more easily cleaned from weeds. Where the garden is small, and where only a small space can be spared for a bed of Onions, it will be found the most profitable way to sow the seed broadcast, using about 2oz. of seed to a bed 18 feet long by 4 feet wide. Before sowing, whether on the drill or broadcast system, it is a good plan to moisten the seed with water, and, after rubbing it about in a cloth until every part of the seed is nearly dry again, then to sprinkle some flour or lime amongst it. As the seed then becomes white, you can see where you have missed sowing, and by this means lay it on more evenly. Always put in plenty of seed, as you can easily thin out if the plants are crowded. Early in March is the best time for sowing Onion seed for the main crop, or even earlier if the land can be caught in a fit state. Onion seed lies a long time in the land before sprouting; therefore, sow as early as you can—the plants then get the full benefit of the heat in summer. Onions sown late often grub off. Thin out the plants carefully by degrees, a few at a time. When they are a foot high, or thereabouts, you may give them a final thinning, always taking care to leave such plants only as show the most blade leaves. I once asked an aged cottager in Lancashire, who was growing for exhibition, why he was so very particular about thinning out the plants? He replied by asking me the following question: "Do you think a scallion with three-blade leaves can ever make as large an Onion as one with five-blade leaves? Do you not know that every leaf-blade makes a fold round the Onion, and that five folds will make a larger Onion than three folds?" I saw that the old man's idea was quite correct, and have adopted the plan ever since.

Remedies for Maggots.

During June, Onions are much troubled with the maggot. If the young Onions turn yellow and drop on the ground, they are attacked by a fly, *Anthomyia ceparum*. The grub which does the mischief is white, shiny, and cylindrical; it measures from a $\frac{1}{4}$ to $\frac{1}{2}$ an inch in length; it eats its way into the heart of the Onion and destroys it. As the fly lays its eggs within the leaf-sheaths of the plant close to the ground, any noxious top-dressing not injurious to the plant may be used to keep the fly at a distance. The beef fly would not deposit its maggots on the Onion, neither would the Onion fly deposit its maggots on the beef. Every fly has a nature of its own, which cannot be changed. Tansy, Mint, or any other strong herb, placed on a piece of beef, throws the beef fly off its scent, and it will not alight on it, or attempt to deposit maggots thereon. The Onion fly can smell the Onions growing on the bed, and it will not lay its eggs on any other plant; hence, soot with guano, or gas lime from the gas works, when thrown broadcast on the bed, are excellent remedies; for these top-dressings not only throw the fly off its scent, but they stimulate the young Onions into a vigorous growth, and they soot get both too large and tough for the young maggots to penetrate, who thus die for want of food. The fly only attacks Onions when they are very young and in a tender state. The best remedy known is a heavy top-dressing of soot, and it is astonishing what a large quantity can be used without injuring the plants. I may here mention that nothing equals a top-dressing of soot for Carrots when attacked by maggots deposited by the Carrot fly. As the Onion will root down from 18 inches to 2 feet, deep trenching and plenty of manure are necessary, and will be found the best preventives of the vermin that destroy the Onions.

Varieties.

The best for spring sowing and a profitable crop are White Portugal, James's Keeping, Reading, Strasburg, and Deptford, the two last rather strong in flavour, but good croppers and good keepers. Those who are fond of eating young Onions should make a bed and sow it with the Giant Rocca, a new variety only lately introduced; its flavour is much milder than any other Onion, and it is good to eat with Cucumber. The Giant Rocca can be grown to an immense

size—8 inches in diameter, and 2 lb. in weight. It is now very commonly exhibited above that weight; but, in order to grow it to its full size, the seed should be sown about the middle of August; and, in the month of March following, the young Onions should be transplanted into a very rich bed, in drills 9 inches apart. Unfortunately, the Giant Rocca does not keep for any length of time; but its fine mild flavour, combined with large size and a beautiful appearance, recommend it strongly to every one interested in the growth of fine Onions. Other varieties that will keep can be grown this way to a very large size, when they are wanted for exhibition, such as Blood-red, Danvers Yellow (very handsome), White Portugal, Flat Madeira, Deptford, and White Globe, all of which attain a very large size. For ducks, in July and August, no Onion is equal to the Giant Rocca for stuffing.

Advantage of Raised Beds.

In order to grow good-sized Onions, one grand result is obtained by raising up the beds, and this is done by throwing up the soil from the alleys; the bed should be left in a rough state during winter, in order to get it pulverised by frost. It is impossible to do justice in sowing the seed unless the surface is in a somewhat fine and friable condition, like a potting compost. One good result of raising the beds is greater certainty of ripening the crop; in fact, it is a very important matter. Anyone can grow a fat Onion with a sappy neck; but the perfection of Onion-growing is to have them large, hard, and the growth so completely finished that the top is withered at storing time. Whilst the Onion is growing it should receive no injury—not a leaf should be bruised nor a neck broken; and, though it may be necessary to break their necks in order to promote ripening, the practice is a proof either that the season is too damp, or the soil too rich, or the management faulty. When the alleys are thrown up, it naturally follows that the beds are better drained, and the Onions are warmer at the roots; gross, thick-necked Onions are produced by rank sour manure and want of drainage. Deep digging in winter causes the superabundant water to sink into the soil, and this process is absolutely necessary in strong rich soils. Another good point is obtained when the plants are kept clean and free from weeds. As soon as you perceive the young plants commencing to bulb, administer, once a week, doses of strong manure-water, which may be made in various ways. A peck of sheep's dung in about twenty gallons of water is excellent. Another good liquid manure may be made by mixing half-a-pound of sulphate of ammonia with twenty gallons of water. If regularly fed, they will grow to a great size, especially if they have a hot season. When you perceive the bulbs beginning to ripen, cease feeding them with liquid manure. In order to cause the bulbs to swell, it is necessary to bend the tops down, just above the crown of the bulb, by drawing the back part of a rake over them. In about a fortnight afterwards, if the weather should be fine and dry, the crop may be pulled up and laid on the bed, or any dry place, for about three or four weeks, turning them over occasionally. When the tops are dead you may tie them up in bunches, and store them in any building. They keep well hung against a wall in an outhouse or garden-shed. In some parts of Lancashire, gardeners hang them up in bunches against the garden-walls, where they remain all winter, and are taken away as wanted. Onions, like Strawberries and Roses, are fond of a dry sunny heat at the surface whilst their roots are wallowing in a rich moist soil below. I have seen whole fields of Onions grown with soot and salt dug into the soil. Long beds 4 feet wide were made, the alleys being deepish, and the surface of the beds was raised a little in the centre, in order to throw the water off quickly during excessive rains. These beds were sown liberally with seed broadcast, and the work of weeding and thinning out was done by boys and girls. Onions can never be grown successfully on a light sandy soil—they always grub off; but there is a very large Shallot now grown, of a reddish colour, which yields an immense crop, and which can be grown successfully in any light garden soil well manured; and the Potato Onion and the Tree Onion will also grow in rich light soils. Let the bed be gently trodden down, and then raked level: lay on the garden line close to the soil for the whole length of the bed, beginning at one side; then with the back part of the rake, the head of which should be straight, make a very shallow trench close to the line, by pushing away a little soil for the whole length of the garden line; after which move your line about 7 or 8 inches for the next drill, and, in the same manner, make another drill by pushing away a little soil with the back part of your rake-head. In this manner go on until three or four trenches or drills are made, which must be very shallow; then sow your seed, and proceed to make more drills and sow again, until your 5-foot bed is all drilled; cover up your drills with the rake, and pat the bed down gently; then finish off with the making a pathway on each side of your bed.

H. T.

CULTURE OF HORSERADISH.

DID you ever plant Horseradish with an iron bar? No; what a singular question to ask. Well, my friend, you may think so, but such is, in fact, not the case. You may say, perhaps, that Horseradish, like many common plants, will grow anywhere, and so it will. But to have it good it must be grown well. Some years ago, when I was in the West of England, I had charge of a very old and a very productive garden, in which was a large bed of Horseradish, situated in a prominent position, and yet it contained no useful piece longer than from 4 to 6 inches. The first winter I was there, I had a bed made in the least frequented part of the garden. I trenched the spot selected for the bed about 2 feet deep, adding a good dressing of dung, and allowed the bed to settle down well before planting. I then trenched the old bed fully two feet deep, and carefully picked out every bit of the Horseradish. There being plenty of crowns, we saved the best of them, and cut away every bit of side root; some of these crowns had pretty firm bits attached to them of from 2 to 6 inches long. These were allowed to remain, and the strongest were selected for planting. After the crowns were gone, we used some of the best of the roots, the longest, strongest, and straightest; these had no crowns, but, Horseradish cares little about being beheaded, and when the genial influence of summer begins to act on it, it soon pushes forth a new head. When our freshly-made bed had become pretty well settled down, we took an iron bar, and with it made holes in the bed about 15 inches deep, leaving about as much between the rows, and about one-half that distance hole from hole. These holes were made to remain open, at least, for a time, and, in order that they might be a little wider at the top than at the bottom, the bar was made to play round about once or twice before it was withdrawn. This also firmed the sides. Into these holes we dropped the sets of Horseradish; enough of loose earth is sure to sink down in the operation to keep the young rootlets all right; and the open hole assists vegetation. It was said the new man had destroyed all the good old bed in which one always found some Radish; and, moreover, the new bed was planted so deeply that it was believed the plants and cuttings would never see daylight. Before, however, the roast beef graced the next Christmas dinner-table, there was in this new bed plenty of good and cleanly-grown Horseradish, more than 1 foot long, and between 2 and 3 inches in girth. As to lifting Horseradish, this should never be done hap-hazard all over the bed, as, by doing so, one never knows where to pitch upon a good root when such is wanted. In taking the Radish from our new bed, we began at the end where we had planted the strongest crowns. In autumn, we had a couple of yards along the bed dug up, from side to side; all the sticks fit for use were carefully put aside into a convenient place, amongst some mould in an open shed. This portion of the bed was levelled down into its former place, and planted afresh, and thus we went along the bed, lifting according to the demand, and no more gnarled and twisted Horseradish, of 2 or 3 inches long, was to be found.

GEORGE DAWSON.

New Road, Barnet.

RUNNER BEANS.

THERE is not in the whole range of summer vegetables a more useful, and, when well cooked, a more delicious dish of green food than the Scarlet Runner Bean. Its great cropping powers are proverbial, and the more its pods are gathered the more abundantly are they produced, and the plants continue to furnish an unfailing supply until early winter frosts come and destroy them. I do not, however, intend to place the Scarlet Runner before the White Dutch, which differs from the Scarlet only in having its flowers and seed white, and in the latter, not being so large as that of the Scarlet. The Beans of the White Dutch are also cheaper, and rather earlier than those of the Scarlet. These Runner Beans deserve a better degree of selection than they usually obtain, but where great breadths are grown, whether for market or for seed, it is difficult to give them the requisite attention. Acres of them might be continually examined, and yet not a single plant or pod be found that appears to be more than

ordinarily fine; yet, if time and care can be bestowed, without doubt, it would be amply repaid. It was in this way that a valuable selection of the Scarlet, known as the Champion Runner, originated; and, I believe, that it has well maintained its original character of being a very fine podded kind. In the hands of ordinary growers, a fine Bean of this kind is apt to speedily degenerate, especially when all the best pods are gathered for table use, and the worst left for seed. To maintain its true character, a short row should be left to furnish a seed supply, and of these, when ripe, the finest pods and the finest seed should always be selected to furnish the seed stock of the ensuing year; thus, by care and attention, no deterioration would ensue. The finest samples of any Runner Bean that I have yet seen originated in a selection from the White Dutch, one pod alone having been found larger and broader than usual, and its produce of four seeds were saved and grown last summer. These produced a good crop of remarkably fine pods, averaging six inches in length, and an inch in width, very flat and straight. If this selection should again, next year, keep up to its fine form, it will, without doubt, prove to be an acquisition. We hear a good deal at times about new things, vegetables especially, being simply old faces under new names, and that this reproach attaches to a large number of so-called new vegetables there can be little doubt. In some cases, however, we find amongst novelties really superior forms of old things that have been obtained only by careful selection, and these often well deserve some special designation, and an enhanced price—the only meed of reward offered to the careful grower. There are some excellent kinds of Runner Beans that are by no means commonly grown, but are yet of great special merit, and afford, also, differences in quality and flavour that make them specially acceptable. Let the Scarlet Runner be ever so delicious, yet one may tire of eating it every day for weeks in succession, but if the gardener can furnish alternately dishes of other equally good kinds that differ in character, the pleasure of partaking frequently of Runner Beans is enhanced. Two of the very best of these runners are the Eclipse and the Premier, both little known, but when known much appreciated. The Eclipse is a tall strong-growing kind, having vine and foliage resembling those of the old Caseknife. The pods are long, flat, and straight, and are quite tender even when old. It is a heavy cropper, and furnishes a very abundant supply. It is also earlier than the Scarlet Runner, and thus assists to lengthen out the Bean season. Ripe seed of Eclipse is medium-sized, flat, and in colour dull green flaked with dark red. Premier differs entirely from Eclipse, inasmuch as it is really a Runner form of the dwarf trench Bean, and as its character has been, in this respect, well maintained for the past ten years, it is, therefore, perfectly reliable. A few years since, when grown with a large number of other kinds at Chiswick, it was considered sufficiently meritorious to receive a first-class certificate, and since then in its peculiar form it has not been excelled. The ripe seed is, in size and shape, similar to that of the Early Dun Dwarf, but it is, in colour, deep red and marked with dark spots. The plant grows to a height of about 5 feet, and does best on ordinary Pea-sticks. It commences to crop close to the ground, and continues to bear heavily until the winter. The green pods are very tender and delicious when cooked, and it is altogether a really useful garden vegetable. The coloured-podded Beans are more novel in appearance than useful as table vegetables. The purple-podded kind partakes of the old Caseknife habit of growth and foliage. The pods are long, but soon fill with the seed. They are, as the name implies, purple in colour, and, therefore, not at all desirable at table. The blooms are also purple, and, for a short time, look pleasing and attractive. This Bean may be useful, and possibly ornamental, to grow as an ordinary climber; but it has no useful place in the kitchen garden. The latest novelties among Runner Beans are the Wax-podded and Yellow-podded, or Butter Beans, the latter name being given more out of compliment to the colour of the pod than to its table quality. These are termed skinless; or, rather, like the pods of the Sugar Pea, they have no lining, and are to be cooked and eaten whole. The colour is most objectionable; however, whilst, in flavour, the Bean is not equal to our green kinds.

A. D.

AUSTRALIAN SPINACH.

At the commencement of last year, Mr. Ramel, who introduced into the French colony of Algiers the *Eucalyptus globulus*, received from Australia this new vegetable. His friend Baron Mueller, of Melbourne, had it sent to him as a substitute for Spinach. He called it New Queensland Spinach. The New Australian Spinach is, however, a better name for it. It belongs to a group in which is comprised our common Spinach; it answers botanically to the *Chenopodium auricomum* of Lindley, who described it in a few words in Mitchell's "Journal on Tropical Australia." It grows abundantly in the east part, following the course of the River Narrau, and it is again found in Queensland. The *Chenopodium auricomum* resembles in general appearance *Chenopodium hybridum*, that troublesome weed which overruns our fields, except in certain points, especially in the inflorescence. The stalk is erect, robust, angular, fluted, and streaked with a violet kind of red. Mr. Barron, who tried it fairly at Chiswick, says:—"The quantity of leaves that can be gathered from a few yards of it is enormous. When cooked in the summer time it was found to be somewhat strong-flavoured and fibry, but, on again trying it, it proved much more tender, not unlike 'gude kail' in Scotland when well frosted, with a smack of the Spinach flavour in it. It lacks the mild flavour of the true Spinach so much relished by some, but will prove a very good substitute, in times of scarcity, and is very easily cultivated." It may be sown in the open ground in March, April, or May. Baron Mueller states, that this *Chenopodium* "is very palatable and wholesome, and remarkable, also, as a perennial plant among allied species. It grows taller than most kinds of *Chenopodium*. In England, it would die down to the root in winter, but it would be, with the return of warm weather, likely to spring again from the root; on early sowing it would likely produce seeds in the first autumn." Messrs. Stuart & Mein, of Kelso, who introduced this Spinach into this country, some few years ago, say, that the seed may be sown in the open border in April and May, but in March under glass; and, when the plants are strong enough, they put them out about 9 inches apart. They state that they have now plants in seed-pans about 1 inch in height, with stems like the finest needles. These, a few weeks after transplanting, will attain to the height of 6 feet, and will yield abundance of leaves. In appearance, this Spinach resembles what is called in this country "Fat Hen" (*Chenopodium album*).

Vitality of Cabbage and Melon Seeds.—In an article on germination (see p. 164), Cabbage seed is put down as not being to be depended on after five years, and Melon seed is set down the same. Now, lest anybody might be induced to throw away valuable seeds on that information, I beg to give my own experience in the matter of Cabbage seed. I have possessed, for many years, a very valuable kind known as the McEwen's Cabbage, and have been in the habit of using seed of it which had been kept as long as twelve years, saved by myself. I find, however, that when sown on a hot-bed, like Cauliflowers, the percentage of germination is three-fold what it is when sown in the open ground. I keep the seed in the pod. As regards Melons, I have eaten Melons grown from seed known to be more than forty years old; it was found in a drawer after the death of a former proprietor, carefully labelled and described, so as to preclude any chance of a mistake.—L. W.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Centranthus macrosiphon as a Salad Plant.—This is described as resembling Corn-salad or Lamb's Lettuce in flavour, but is said to be "less insipid." As a matter of course, it must be cut over when young if required as a salad.

Good Ground for Early Potatoes.—Jonathan Talcott, the well-known Potato-grower of Rome, N.Y., tells the *Boston Cultivator* that repeated experiments have taught him "that early sorts require richer land to give their best yield, as they grow in less time, and, consequently, must be better fed, or they are, of course, small, and the crop will not be remunerating."

Turnip and Onion Drill.—What is the best drill for sowing Turnips and Onions on a level surface, to be drawn by one horse? I want one that would draw and sow six rows of Turnips at one time, 14 inches apart, so that it could be regulated to sow six more drills of Onions at 7 inches apart; if there is such an implement, it would be very useful for market-gardeners.—W. C., *Whitehaven*.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE THICK-LEAVED MAPLE (ACER CORIACEUM).

THIS kind forms a branching tufted tree from 20 to 30 feet high, with opposite, short, stiff branchlets, thickly clothed with foliage; the shoots, when young, are downy, but, when fully matured, quite smooth, and, when leafless, of a chestnut-brown colour, furnished with small obtuse, smooth, imbricated buds. It is a native of the French Alps, and was introduced in 1812. The leaves are mostly three-lobed, but sometimes they are slightly five-lobed; they are thick and somewhat leathery in texture, quite smooth on both surfaces, deep green above, light green beneath, nearly square, or slightly cordate at the base, on rather long foot-stalks, and three-ribbed beneath. The lobes are broadly ovate, a little pointed, bluntly and irregularly toothed on the edges, and nearly equal in size. The flowers are small and in loose corymbs. The fruit or keys are smooth and about one-third the size of those of the common Sycamore, with rather narrow cultriform wings, rounded at

The Thick-leaved Maple. (Leaf natural size.)

the ends, and somewhat spreading. This kind is frequently named *Acer opulifolium* in the nurseries, and is the kind described in the abridged edition of Loudon's "Arboretum," under the names of *Acer Pseudo-platanus opulifolium*, *A. obtusatum coriaceum*, and *A. Opulus coriaceum*. The length of the leaf is from 4 to 4½ inches, including the foot-stalk (which is from 1¼ to 1¾ inches), and the breadth from point to point of the lateral lobes 3½ to 4 inches.

LEYCESTERIA FORMOSA.

THIS useful free-flowering shrub, a native of Nepal, is sufficiently hardy to withstand our English winters, if not very severe, without protection. If, however, the stems happen to get cut down to the ground, they usually push up again in spring, a circumstance which suggests the advantage of mulching the soil over the roots in severe winters, as is often done in the case of Fuchsias. The flowers of the *Leycesteria* are produced in pendent racemes, the scales or bracts of which are more showy than the flowers themselves. They are in greatest perfection in autumn, associating in this respect with herbaceous Asters and Chrysanthemums, but remaining longer in beauty than either of these. The *Leycesteria* does not attain a great height; on the contrary, from 3 to 5 feet is its

common altitude, but I have seen it grow in the Isle of Wight as high as 7 feet, the upper half of the stalks being bent down by the weight of inflorescence which they bore. Although this plant grows well in shrubberies, against walls, as isolated specimens on lawns, and in other positions, I consider an open but sheltered situation, well-drained, and fully exposed to the sun, best for it. Under such circumstances the wood gets thoroughly ripened early, and the chances of its succumbing to the winter's severity are less than they otherwise would be, whereas its flowering properties are enhanced. It is not particular as to soil, for I have seen it do well in soils of almost every kind, but it dislikes a wet stagnant sub-soil. It is also, as far as known, rabbit-proof. It may be increased by means of seeds, cuttings, and division. Seeds, however, do not ripen well in this country, except, perhaps, under a sash. When ripe, gather the clusters, or, better still, perhaps, cut over the points of the shoots, clusters and all, and hang them up in a light and airy room or Vinery at rest, until the seeds become hard. Sow the seeds in February, in pans of peaty soil, placing the pans in a greenhouse, and afterwards transferring them to a frame. A temperature of about 50° is essential until they germinate, soon after which they should be pricked off into other pans of similar soil, but not committed finally to the open ground until they are one or nearly two years old. The common way of increasing the *Leycesteria* is, however, by means of cuttings. For this purpose, in October or November select the best-ripened shoots, strip them of leaves and flowers, and cut them up into pieces, each having two or three joints, their entire length being about 5 or 6 inches. Select a warm border, dig it rather deeply, and incorporate with it a good deal of sand and leaf-soil. Insert the cuttings in clumps, keeping each cutting about 1½ or 2 inches apart, and not more in each clump than can be easily covered with a hand-glass. Here allow them to remain till spring, but cover them up at night and during frosty weather. In spring, when they begin to grow, all dead ones must be picked out, in order to give the others more room. In June most of them will require shifting, therefore, prepare a border for them as before; lift all the plants, select the strongest, and plant them in rows 9 inches apart and 3 inches asunder in the row; the weaker ones may also be transplanted in the same way, but at a less distance apart. Introduce a few twigs of evergreens amongst them for a few days until they recruit themselves. Here they may be left until fit for permanent transplantation. The cuttings might have been put in cold frames, and, if taken in time, they may be struck in the open border and protected with branches. Division consists in separating the large root-stocks into two or more separate plants, when good specimens are at once secured.

W. F.

NEW CONIFERS.

THE following new Conifers have been recently introduced by T. C. Maxwell & Co., of Geneva, N.Y., and have decidedly valuable characteristics.

Thuja occidentalis argentea.—A very curious and beautiful dwarf form of *Arbor-Vitæ*, and wholly unlike any hitherto described. It is of a fresh green colour, with the branchlets distinctly tipped with white. It is believed to be entirely hardy, having been exposed as thoroughly as the George Peabody, and with no injury. It is very attractive and pleasing in appearance, and has the same parentage as *T. o. lutea*.

Maxwell's Dwarf Spruce (*Abies excelsa Maxwellii*).—A seedling, which originated on the grounds of T. C. Maxwell & Bros.; leaves, short, rigid, dark green. Its habit is very compact, full, and regular, and, without trimming, its tendency is to form a dense hemispherical mass. The original plant is fifteen years old, and measures 24 inches in height and 38 inches in diameter. It is more vigorous than *Pygmaea*, and somewhat larger. For novelty, this little tree is curious and interesting, and as a beautiful low evergreen, this dark green regularly rounded dwarf is exceedingly valuable.

Glory of the Spruces (*Abies alba aurea*).—This tree has a unique beauty of more than ordinary character. In size and habit, it resembles the common American, from which it is a chance seedling; leaves, long, curved, of a soft, glaucous colour, and very thickly set upon the branches. A rich golden-yellow distinctly marks and dorns the tips of the leaves upon the upper side of each shoot. Nora

is this colour faint and undecided, but reliable, pronounced, and striking; so that this silvery-green and gold foliage at once attracts and fixes attention. Standing in front of a group of darker and larger evergreens, the effect is remarkable.—*Agriculturist*.

Effect of Lightning on Trees.—The comparative immunity of different kinds of trees varies considerably. It is stated that the Oak and Italian Poplar have great susceptibility to injury, while other trees, especially the Birch, most frequently escape; but much of the difference may be otherwise accounted for than by difference of susceptibility, which, however, gives probably a partial explanation. Oaks and Poplars are generally taller trees than Birches, and electric clouds must, therefore, more frequently come within striking distance of their tops; such trees are more numerous than Birches, and more frequently grow apart from other trees, and when apart are more exposed to lightning. Again, the upper branches of those trees are larger in proportion to their trunks than those of the feathery Birch, and can conduct stronger shocks than its slender spray can; their roots also strike deeper into the soil, so that more electricity may pass through their trunks in the same time than through the trunks of those whose roots, being in shallow and dry soil, are partially insulated, or, rather, imperfectly connected; if they were perfectly insulated they could not convey a shock at all. Further, a tree, when struck with lightning, is less likely to be injured if its trunk and large branches be wet, than if dry. But trees with heavy foliage, like Oaks and Poplars, will be longer in getting wet than Birch trees with light foliage, and be on that account more likely to be injured. From these, and other considerations, we do not think that the comparative immunity of Birch trees from injury by lightning (and it is comparative only) proves Birch-wood to be less susceptible to injury than other wood, if other circumstances were similar. It very possibly may be so; it is not unlikely that, being a quick-growing tree, with many sap-vessels, it is so, but that is not proved by the mere fact that Birches are but seldom destroyed by lightning, which is generally believed to be the case.—Q.

Tree-planting in Nebraska.—Only on the banks of rivers and streams is there natural wood in Nebraska. But forest trees take kindly to the prairie soil, and are being planted by millions. The Hon. J. Sterling Morton, of Nebraska City, who has been one of the foremost in the tree-planting movement, suggested the expediency of setting apart a day in the spring-time every year to the special work of tree-planting. The first "Arbor-day," as it is called, was in 1871, and on that day two million trees were planted. Next year, and the year after, Arbor-day was dropped; but the month of April was recommended to all to choose a day for themselves. This year, however, the State Agricultural Board has determined to go back upon the original idea, which is that, upon one special day in the year, each person owning land shall plant at least one tree. It was resolved that the time should be the second Wednesday in April, and that the State Legislature should be asked to make the day a legal holiday. Nebraska will thus get a spring-tide holiday, the main recreation of which will be tree-planting and attendant festivities. A premium will be awarded for the most trees planted on that day. It is now the custom of the State Board of Agriculture to present a premium for the largest number of trees planted any day in the month of April, and, at a meeting of the Board last January, the prize was awarded to a farmer, who planted 27,800 trees on April 28, 1873.—CORRESPONDENT.

Idesia Polycarpa.—This fine hardy plant comes from Japan, and appears to have been distributed from the Botanic Garden of St. Petersburg. It was exhibited in 1867 at the Paris Exhibition, by M. Linden, as a fruit tree from Japan, and was afterwards put into commerce under the names of *Polycarpa Maximowiczii* and *Flacourtia japonica*. The generic name *Idesia* was given to it by Maximowicz, and is now adopted by all botanists. A figure of it published in the *Revue Horticole* (1872, 174) represents a specimen bearing only ripe fruits, sent by Maximowicz to the Paris Museum, and which was described as coming from a cultivated tree, 40 feet high, growing on the island of Nippon, in the neighbourhood of Mount Fusi, while other specimens, probably wild, bearing only male flowers, were from the forests of Kinosau, in the island of Kiusiu. Whether or not it is likely to become a useful fruit-bearing tree may be questioned, but there can be no doubt it is a fine ornamental plant, and thoroughly hardy. Its trunk is said to be straight and robust, its branches spreading, and its leave caducous. The latter are alternate, cordiform, acuminate, deeply toothed, having cylindrical red petioles, 8 to 12 inches long, and bearing, at some distance from the base, two stout projecting glands, two, or often three, others occurring at the point of insertion of the limb, which is thin, soft, 10 inches long, 8 inches broad, of a glaucous-green, whitish beneath, with reddish

venation. The flowers are dioecious and apetalous, while the fruits are bacciform, about the size of a large Pea, fleshy, of a fawn-red, or reddish-orange colour. This species, M. Carrière observes, presents a rather rare peculiarity in its growth, which is, also, met with in *Magnolia grandiflora*, namely, the development of a lower bud, which takes much larger proportions than the others, and tends to widen the head, to the damage of the central axis. Hence, if the plants are wished to grow up, pruning will be necessary. It prefers warm calcareo-silicious soils, and is found to propagate freely by means of root-cuttings.—*Florist*.

Pruning Shrubs.—The "Gardeners' Monthly" gives a list of such shrubs as flower on the wood of the preceding year; and another list of those which bear flowers on the present season's growth—the former to be sparingly pruned in winter, so as not to cut away the flower-buds; the latter bearing more severe pruning. Those bearing flowers on last year's growth are, Dwarf Almond, Snowy Mespilus, the *Andromedas*, *Azaleas*, and *Kalmias*, *Rhododendrons*, *Calycanthus*, *Corchorus*, *Leatherwood*, *Fothergilla*, *Cornelian Cherry*, *Philadelphus*, *Deutzia*, *Mezereon*, *Hydrangea*, *Itea*, *Jasmine*, *Privet*, *Bush Honey-suckles*, most of the early *Spiræas*, the ornamental *Currants*, *Weigela*, *Snowberry*, *Lilacs*, and *Annual Roses*. Shrubs that flower in the present season's growth, are *Ceanothus*, *Amorpha*, *Colutea*, *Euonymus*, *Genista*, *Shrubby Hypericums*, *Coronilla*, *Scotch Broom*, *Althæa*, *Flowering Locust*, *Tamarix*, and late *Spiræas*. Our own opinion is, that these, and all other shrubs and flowering trees, are much better without systematic pruning of any kind, than with it.

Oldest Worked Wood in the World.—Probably the oldest timber in the world, which has been subjected to the use of man, is that which is found in the ancient temples of Egypt. It is found in connection with stone-work, which is known to be at least 4,000 years old. The wood, and the only wood used in the construction of their temples, is in the form of ties, holding the end of one stone to another in its upper surface. When two blocks were laid in place, then it appears that an excavation about an inch deep was made in each block, into which an hour-glass-shaped tie was driven. It is, therefore, very difficult to force any stone from its position. The ties appear to have been the *Tamarisk*, or *Shittim wood*, of which the ark was constructed, a sacred tree in ancient Egypt, and now very rarely found in the valley of the Nile. These dove-tailed ties are just as sound now as on the day of their insertion. Although fuel is extremely scarce in that country, these bits of wood are not large enough to make it an object with the Arabs to heave off layer after layer of heavy stone for so small a prize. Had they been of bronze, half the old temples would have been destroyed ages ago, so precious would they have been for various purposes.

THE PINE.

THE mountain owns its oread, and the stream

Its naiad; lo, the dryad of the Pine!

How stern and lofty! sorrow, how divine

Its murmurings speak! but let the lightnings gleam

Around it, and the storm hold fearful reign,

Lo, the proud warrior! with what calm disdain

He braves the utmost fury! all forgot

His sorrow, for great souls remember not

Their trials when great troubles come; they call

The poised soul up; and great hearts do not bow

To tempests, but with calm uplifted brow

Dare the wild worst; dark stormy troubles fall

Upon the strong to try them; weakness bends,

Strength grows more strong, and vain the storm its fury spends.

—ALFRED B. STREET.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Hardiness of the Chinese Arbor-vitæ.—Mr. Sergeant, of Boston, informs us that while thousands of the Virginian bedders were killed in the Northern States, of which it is a native, in the frost of 1871, the Chinese Arbor-vitæ everywhere escaped.

Rate of Growth of the *Adansonia* in India.—The following are measurements of a tree in a garden at Alipore (Calcutta), Dec. 3, 1873:—Girth at base, 49 ft. 6 in.; girth 4 ft. up, 46 ft. 6 in.; girth above lower branch, 38 ft.; girth of lowest branch at base, 22 ft.; height, above 80 ft. Mr. Grote, in whose garden the tree grew, measured it March 23rd, 1850. Girth 1 ft. from the ground, 42 ft.; girth about 6 ft. up the stem, 38 ft.; The base-measurement gives an increase of 7 ft. in the twenty-three years.—*Journal of Botany*.

Zenobia (*Andromeda*) *speciosa*.—No planter should forget *Zenobia speciosa*, better known, perhaps, as *Andromeda speciosa*, whose flowers grow in clusters, and are of the same shape as those of the Lily of the Valley, but much larger, and of the purest transparent waxy-white. There are several varieties, differing in the shape of the leaves, and in the size of the flowers. One variety, called *pulverulenta*, from the glaucous under-surface of the leaves, perhaps, surpasses the others in beauty.—*Florist*.

GARDEN DESTROYERS.

THE WHITE THORN MOTH.

(YPONOMEUTA PADELLA.)

For many years past no one can have passed in spring through the suburban lanes around London without observing that the Thorn hedges seemed in many places entirely destroyed, the plants covered with webs as if an army of spiders had passed over them, and the leaves almost entirely gone. This destruction is early, but not coeval with the expansion of the leaf. When the leaf first appears, the hedges rejoice the soul by their fresh green beauty. Return in a fortnight, and everything is blasted. This blast is not confined to London. It will be found all over the country, but, whether it is that it is really worst in the neighbourhood of great cities, or that observation is more rife or more acute there, it is certainly at Paris, London, Edinburgh, Birmingham, and such places that we have most noticed the prevalence of this scourge. It is the work of a small moth, *Yponomeuta Padella*, closely allied to another species—*Yponomeuta cognatella*, also one of our insect enemies, which has been already described and figured at p. 357, vol. IV., of *THE GARDEN*. Their habits, manners, and mode of life are similar, with the exception that the trees the present species devastates are the Thorn, the *Prunus Padus*, and sometimes the Cherry. The larva is of a brownish hue, marked on the back with two rows of spots of velvet-black. The head is shiny black, the under-side pale dirty green. The perfect insect differs from *Y. cognatella* in having the ground colour of the upper wings of a leaden hue, the internal margin alone approaching white.

The White Thorn Moth.

The plan suggested for the destruction of the *Y. cognatella* may also be applied to this species, viz., sweeping the hedges with a stiff broom, but it is a feeble attack on a powerful enemy.

A. M.

Effect of Feeding on the Colour of Cocoons.—The art of silk culture is likely to be materially advanced by the discovery of Taillis (if it be true) that when the worms are fed on Vine leaves the Cocoons are of a magnificent red, and if Lettuce be used, they become an emerald green. Another experimenter has obtained silk of a beautiful yellow, a fine green, and then again violet, by feeding with Lettuce or white Nettle. Taillis remarks, however, that the worms must be fed on Mulberry leaves when young, following with other leaves during the last twenty days of the larval stage of life.

Great Swarm of Insects.—In a letter to the *American Journal of Science and Arts*, dated Cordoba, September 18, 1873, Dr. Gould gives an account of a remarkable swarm of large grasshoppers, or locusts, recently witnessed there. Myriads filled the air, invaded the houses, and covered the ground, from which they rose like thick clouds of dust, on approach of man or beast. These, however, seem to have been merely the stragglers of the main body. Going out to observe the phenomenon more closely, Dr. Gould saw, to the eastward, what looked like a long trail of dense black smoke, extending over 160° of the horizon, and to an altitude of about 5°. A strong field-glass showed that it was no smoke, but a swarm of locusts. Its width there was no means of determining, but from the position of the focus needed for resolving the cloud at its point of nearest approach, Dr. Gould estimated that none of the swarm passed within less than three or four miles. The insects were evidently transported with the wind, which blew from the north.

Crickets.—My glass-houses are greatly infested with crickets, which injure my plants. I have tried every means I know of to destroy them, but without success. Can you give me any information in the matter?—E. J. [Crickets are often troublesome in plant-houses, especially amongst soft-wooded cuttings or young seedlings; but they are somewhat eccentric as to food. In some places they will devour greedily a particular plant; and, in others, they may exist in quantities, and not even touch the same plant. I have even had crickets in some houses, and not been able to detect their molesting anything; although, at the same time, there were numbers of things which they usually eat. Where troublesome, they can easily be destroyed by means of beetle-poison, laid down in the same way as for the beetles.—T. BAINES.]

THE GARDEN IN THE HOUSE.

MONEYWORT AS A WINDOW PLANT.

(LYSIMACHIA NUMMULARIA.)

THIS favourite British creeper (commonly known as Creeping Jenny, Moneywort, and Herb Twopence) is alike useful for the decoration of windows, herbaceous borders, rockeries, and rooteries. It flourishes as well in bright sunshine as in shade, producing abundance of long trailing shoots, thickly clad with opposite roundish shining green leaves, and, from early in summer till late in autumn, it presents a mass of bright yellow flowers, about as large as a shilling, set on short foot-stalks. For pot-culture, use strong plants and an open turfy soil, well enriched with rotten manure—particularly cow-dung—and, after the plants begin to flower, supply them liberally with liquid-manure. When grown in pots, suspended like baskets, the shoots hang down long and gracefully, and completely hide the pots, but even then the plants exhibit a flat-headedness that is rather objectionable. This may be obviated by the following plan, which we saw carried out in a garden in Somersetshire, and which we thought extremely effective: Pots rather wider in proportion to their depth than we commonly use, and about 9 inches in diameter at top, had an inch deep of crocks in their bottom, and resting on these in the centre of each pot was a nice stubby plant of the common or narrow-leaved Myrtle, in large 60-sized pots. Good turfy loam, mixed with decayed and dried cow-dung, was then filled in all round, and in this the Creeping Jenny had been planted in March, and grown on in one of the greenhouses till June, when the pots were fixed on brackets outside on either side of the windows of the house, and when we saw them a month afterwards—in July—the Creeping Jenny had hidden the pots, and was in full flower and leaf. The fresh and green Myrtles were pictures of health. Unless the plants in pots can get a good place free from drip in a frame window, or greenhouse throughout the winter, the safest way of preserving their vitality is to turn them out of their pots and plant them in the border for that season, and lift or re-pot them in March. They have a grand effect when planted near the edge of a window-box or vase, and permitted to scramble over the edge and hang down; but, under no circumstances should they be subjected to drought. In the open border or rockery they soon make a home for themselves, provided they are kept out of the reach of other rank-growing plants, which might overgrow and choke them. As its shoots travel along the surface of the ground, the Creeping Jenny sends forth roots from every joint; consequently, it is readily propagated; for every bit of a shoot will form a plant if pricked into open soil moderately damp and shaded. Whole tufts or stocks of it, too, may be lifted in spring, just when growth begins, divided into as many little pieces as have roots, and every one of them will make a nice plant before summer arrives. It must not be expected that every plant will fill a pot; it will take a few small ones or one large one to do that. Plants may be gathered from hedge-banks or moist meadows, for naturalisation in the garden. We have now a valuable variety of the Creeping Jenny with yellow leaves; but it is scarcely so strong or vigorous in constitution as the green-leaved kind. It is very useful in the flower-garden, and particularly so for small cultivators, as it requires no protection in winter, being quite hardy, and making a good subject for an edging in the spring. It may remain in this position during the succeeding summer. It retains its colour well, and, should it become over vigorous, it can be easily cut in. It is propagated as easily as the common kind.

W. F.

A Spruce Cone Ornament.—One of the prettiest objects I ever beheld is a Spruce cone, filled with sand and Grass-seed, which sprouted and grew out of the scales. It is now as large as a Cocoa-nut with the husk on, and of the most vivid green colour. The Grass grows with a luxuriance that is remarkable. To produce this charming specimen, the cone was baked in an oven till the scales opened out equally. It was then carefully filled with equal parts of sand and Grass-seed, a string tied to the tuft, and the whole suspended in the dark, in a jar with water enough to come half way over the cone. In a week it was placed in the sunlight, when the seed sprouted rapidly, and in a month filled a gallon jar completely. It has been taken out and hung in the window exposed to the air of the room. Every morning it is thoroughly soaked in tepid water.—*Tribune*.

GARDEN STRUCTURES.

RIBBON POSTS FOR CONSERVATORIES.

THE Ribbon Post Company have recently introduced a light and elegant form of iron pillar, which will be found better adapted for conservatories than the pillars usually used in the construction of such erections. The ribbons are made around a mandrel, which is provided on its exterior with spiral intersecting grooves. The latter form a receptacle for the ribbons, which are wound on by machinery, without twist or strain, and in such a manner that the gradual decrease of the pole is compensated for. The first series is put on from right to left, beginning at the bottom; the next, in the reverse direction, commencing at the top. The latter ribbons, of course, overlap, and are, at this stage of the operation, temporarily secured to those beneath them by bolts fitted in holes previously punched in both, so as to coincide exactly at the points of intersection. The core of the mandrel is then removed, causing it to collapse, when the pole is withdrawn and placed upon a cylindrical bar, ready for the insertion of the angle irons. These, previously punched, are secured by rivets to the intersections of the ribbons, the temporary fastenings being taken out. The cap, the nature of which depends necessarily upon the uses to which the post is to be devoted, is then put on; and the base, consisting of various forms, strengthened with extra iron and inserted, for some little distance, with the ribbon, and

Ribbon Posts.

secured to a plate, which affords a strong support, is added. The strength of posts, thus constructed, is said to be very great. Two, without angle irons, measuring 10 feet by 8 inches, supported a weight of 10 tons without sinkage, deflection, or collapse. The total weight of a telegraph post, 31 feet long, is about 434 pounds, and such posts are ornamental and durable; while, as supports for pillar-plants, their advantage over ordinary posts will be at once apparent.

GLASS-HOUSES IN AMERICA.

Your correspondent's, "A. M.," picture of American glass-houses (see p. 20) is considerably overdrawn. Having lived in the city of Philadelphia for more than a year, and in its immediate vicinity for rather better than a year more, I am well acquainted with the establishments to which he alludes. His description of one nursery is, alas! too true, with the exception of the statement that there were no tables or staging in the green-houses; for, having visited them several times, and once a few days ago, I am prepared to say that there are tables in nearly all the houses, excepting such as are devoted to the cultivation of plants for supplying cut flowers; in those the stock is planted out. I may state, however, that the proprietor of that establishment commenced business under adverse circumstances, and when stern necessity compelled him to build his first houses in the primeval style described. Now, however, although he has acquired means, he, unfortunately, has not changed his ancient

system. This case is, however, rather an exception than the general way in which green-houses are erected here. In another establishment "A. M." states he saw the roof stuffed with Sphagnum Moss; in reply, I would say that we frequently have to resort to such means, even in the case of new houses, for the hot sun here so warps the timbers of a house that during the first year the ventilators often get twisted out of place, and we have to look out for small cracks in a country where the mercury frequently sinks below zero. There are now a younger set of men in the nursery business, whose establishments go to show that they have an eye to taste as well as to making money. I could name several nurseries where the green-houses are put up as well as you will find them in many London establishments. "A. M." must have been singularly unfortunate to have fallen into the very roughest of the many establishments about Philadelphia. The firm with which I am engaged as foreman has lately erected five new propagating-houses, and the plan on which they are built is so neat and economic that I will try to describe them. They are 100 ft. long by 8 ft. wide, a 2 ft.-walk runs through each, and on each side is a 3-ft. table. There is only one wall on one side, the other being merely boarded up to admit of extension. The sash, 5 ft. by 3½ ft., rests upon solid oaken gutters, 1 ft. wide, and these are supported by stout posts of the same material. The whole is nicely planed and painted, and presents as neat and attractive an appearance as any five houses could do in England erected for the same purpose. In two of these houses we have 200,000 Conifer cuttings, and we are about to fill the other three with young Roses from the propagating-bed in order to establish them preparatory to planting in open ground. My employers propose to cover a large space with houses like those just described, and, I have no doubt, the most modern improvements will be added to them. It will thus be seen that American horticulturists are not such an antediluvian set as my countrymen in England may imagine them to be.

WALTER C. FANCOURT.

West Chester, Pa., U.S.A.

WORK FOR THE WEEK.

Flower Garden.

Sweep and roll lawns and walks as soon as the weather becomes favourable. Judiciously prune evergreen shrubs, such as Aucubas, Hollies, Bays, Box, Yews, Portugal and common Laurels, Junipers, Thujas, Cypresses, Ivies, &c., which may be out-growing the spaces allotted to them, keeping symmetry and gracefulness of form as much as possible in view. The knife is better than shears for such an operation, the latter being apt to mutilate the leaves. Roses should now be pruned, the plants having in many cases already made shoots nearly an inch in length. As soon as the snow has left us, herbaceous plants should be trimmed, and the crowns should be lifted, divided, and re-planted in deeply-worked well-manured soil; some of the more tender kinds may, however, be left a little longer before being disturbed. Lilies of various sorts, and other bulbous plants, as a rule, thrive best and flower most satisfactorily when left for some years undisturbed. The stock of bedding plants may be increased as expeditiously as possible from cuttings, roots, and seeds.

Greenhouses.

Indoor plants have almost invariably started into growth, therefore, such as require a shift must at once receive that attention. Borders in which plants are growing should be lightly forked up, and if the soil is exhausted a dressing of loam, leaf-mould, rotten-manure, or good peat, may be added, according to requirements. Some plants need more water than others, and, in such cases, neatly-formed basins of soil should be made around them, so as to retain sufficient for their wants without overflowing. This is an excellent time for transferring plants from pots to conservatory borders, and, in doing so, disentangle and spread out the roots as much as possible. This may check growth for a time, but, eventually, other circumstances being favourable, plants so treated will succeed better than such as are planted with the roots coiled up in a ball. Camellias, Rhododendrons, Acacias, &c., when grown in pots, are more under control than such as are planted out; but the latter are generally the most satisfactory, both as regards growth and bloom. Ceanothus puniceus, if too thick, should have its shoots thinned out a little, so as to give sufficient light to the flowers. Passion-flowers should be pruned well in, and the soil in which they are growing should be thoroughly saturated with water, so as to induce them to start freely into growth. Cut in the branches of Habrothamnuses. Several of the free-growing Fuchsias are well suited for conservatory-roof decoration, or that of pillars, especially when planted out in borders. If trained to the rafters from the middle of April until they are completely denuded of side branches in the end of October or November, or for the purpose

of resting them and admitting light to the other inmates of the house; they form objects of interest, being richly laden during all that time with both flowers and foliage.

Forcing-houses.

These, when not wanted for flower-forcing, may be usefully employed for Cucumber-growing. At present, however, keep them supplied with successions of Lilacs, Spiræas, Deutzias, and similar plants. Cuttings of Coleus struck early should be potted as they require it, pinched at the third joint, and the plants should be kept near the light. Iresines form attractive summer objects in conservatories; therefore, treat them like Coleuses. The general stock of Begonias should now be potted and started into growth. Caladiums started in small pots should be shifted into larger ones before their roots become entangled. Continue to force Lily of the Valley; place the plants that have been forced under the stages of the greenhouse a time, and, after that, plant them out, where, if they are well cared for, they will, in two years, make good plants for forcing again. Some plants of *Lilium auratum* should be introduced into this house for blooming in May. In making up baskets for suspending in the conservatory, keep them in the forcing-house until they are in active growth, when they may be gradually hardened off, so as to withstand the cooler temperature to which they are to be subjected. Bring in plants of *Dendrobium nobile* where an early bloom is required, and place those for late use in the greenhouse. Keep up a young and healthy stock of Fuchsias, Heliotropes, Petunias, Balsams, Cockscombs, Hebecliniums, Callas, Schizanthuses, and other plants for early blooming; those treated more hardily flower later.

Frames.

Where bedding plants are largely grown, these must be extensively used, but the frames are not of so much importance as the protecting material. In all cases, the bottom should be dry, or at least incapable of retaining any considerable amount of moisture. The sides may be of turf, bricks, or wood, with rafters or transverse bars for the support of sashes, or for bearing up longitudinal spars or boards, to support mats, canvas, or other covering. Under all circumstances, sashes are the best and most convenient, and these should be drip-proof, and cleanly washed. The material on which the plants stand inside may be sifted coal-ashes, clean gravel, or wood; or a hard bottom, such as a walk, may be covered with 6 or 8 inches of light mould, into which dwarf-growing fibrous-rooted plants may be transplanted six weeks or so prior to being bedded out, after which the soil may be cast out, and a layer of ashes placed in the bottom for the reception of Fuchsias, Cinerarias, and other greenhouse plants. Where frames are the only receptacles for bedding-plants, the exclusion of frost is often indifferently effected, fire-heat, when used, being sometimes of a parching character next the pipes, and only moderate at the other extreme, and coverings necessitate a long period of darkness just when the plants are most liable to damp off, and the atmosphere least drying. An excellent means of avoiding so much darkness and damping, and, at the same time, of preserving the plants in health, is practised by Mr. Cannell, of Woolwich, who, with two rows of 1-inch pipe, run along the inside of the rafters of narrow frames, and three rows in the case of wide frames, manages to have the whole interior atmosphere equally heated, and the greatest winter enemy of soft-wooded plants—damp, kept in abeyance. These pipes can easily be heated from any adjoining boiling, or by means of one purposely set for the frames, if the latter are extensive.

The Kitchen Garden.

This is a busy month in the kitchen garden, and one on which the farmer's success, or otherwise, to a great extent, depends; for if matters having reference to cropping are not systematically performed in proper time, when the soil is in the right condition to receive the plants or seeds, little else but failure need be expected. Matters of cropping, do not stick to any certain rule as to the day of sowing or planting, whether the soil and weather are suitable or not, but first make a good and kindly preparation, by thorough deep culture and turning over of the soil in as rough and open a manner as possible to admit sun and air. In short, turn and re-turn the soil until it falls to pieces like slaked lime, and is in every way so sweetened and pulverised that, by watching the opportunity for a fine day, a large portion of work may be performed. Having all things in order and in good condition is the very keystone of success. It is far better to be a little out of season than to begin cropping in the midst of disorder.

Artichokes.—Finish planting Jerusalem kinds, and from the above varieties pull away decayed leaves, if any, in order to admit to the stools and crowns, and set about early thinning out the weakest shoots.

Asparagus.—Continue to get strong roots into gentle heat; sow seed, and prepare for planting new beds at the end of the month. I always like to see the buds pushing forth before I take up the plants; after which, do not allow them to lie about, but re-plant at once in rows two feet apart, and let the plants stand one foot asunder in the rows. A good deep drill drawn on each side of the line, and the roots spread astride of the drill, will be the right way to plant them, and after two years' time every other row will furnish rare plants to take up for forcing.

Beet.—Sow red for salad use for the whole year, and a small portion of white sugar Beet, for use in place of Spinach—should it be dry and hot in July and August, when Spinach is hard to be got.

Beans.—Of these, plant a full successional crop of Long-pod, Broad Windsor, or some other approved kind.

Broccoli.—Sow all favourite late kinds at once.

Brussels Sprouts.—If not already done, make a full sowing of these without delay; prick out and plant early, in order to ensure large, seasoned, well-ripened plants by autumn, so as to have good solid little heads all up the stems; young, free-growing, late-sown plants will not button or head in to be depended on; a hard-trodden, heavy soil suits them best.

Cabbage.—Sow a small quantity of the Matchless, Nonpareil, Little Pixie, and London Colewort.

Capsicum and Chillies.—Pot off; place them in moderate bottom-heat, and stop at 8 or 9 inches.

Cauliflower.—Plant out now a full crop of winter-stored plants; sow Veitch's Giant and other late kinds, and prick off, as soon as they can be handled, all early sown plants, first in boxes or frames, then on warm borders.

Carrots.—Of these, sow a full crop on some open quarters from this time to the end of the month, in drills one foot apart, using fresh slaked lime as a dressing. This, and a slight dredging of dry chimney soot, applied in showery weather in May, suits Carrots perfectly.

Celery.—Sow a pinch in succession; but we never succeeded so well in the way of obtaining a splendid crisp, solid, lasting crop as when we sowed the first week in April, on a gentle bottom-heat, thinly pricking out again on some gentle hot-bed. In this way some of the plants are soon ready for early planting out; a batch is then pricked out on half-decayed leaf-mould or rotten dung, which can be easily removed with the roots in the form of good balls. In this way no check takes place, and the result is most satisfactory.

Chervil.—Of this sow a pinch of curled, first in a warm situation, and, for succession, in a fortnight, on a north aspect, on account of its starting propensities in hot weather.

Mustard and Cress.—Sow common and curled Cress as well as Mustard, on a warm border out of doors; and Land Cress on a north border for summer and autumn use. Of Watercress make new plantings in shallow streams or damp cold spots, for summer and autumn use.

Lettuces.—Plant out a full crop, and sow, once a fortnight, a pinch of summer kinds, both Cabbage and Cos.

Onions.—Sow a full crop in drills, 1 foot apart, on well-prepared, thoroughly pulverised soil; if light, make it firm by treading or hard rolling.

Vegetable Marrow.—Sow in a little heat, in order to have sturdy strong plants for turning out under hand-glasses when four or five weeks old.

Sweet and other Herbs.—Sow in a gentle heat Basil and Marjoram, and on healthy borders, Thyme, Winter Savory, Marigold, Purslane, Parsley, in full crop, Skirret, Hyssop, Fennel, Carraway, Borage, Balm, Burnet, &c.

Radishes.—Of all kinds of these sow a full crop.

Rhubarb.—Seed of this should now be sown, and large crowned roots divided, to make new plantations.

Parsnips.—Sow a full crop in drills, 1 foot apart, on deeply-trenched, pulverised land.

Peas.—Sow throughout this month on well-trenched, deeply-cultivated, thoroughly-pulverised soil, all the late kinds and the tall sorts, 12 to 14 feet apart; which is not only a convenient distance, but ensures a full supply of light and air to the crop, which is doubled by this treatment; and it forms a partial shade for such summer crops as are planted between the rows. Champion of England, Dixon's Favourite, Harrison's Glory, Laxton's Prolific and Quality, Maclean's Best of All, Prince of Wales, Wonderful, Nonpareil, and Veitch's Perfection are all good Peas for succession; and for the last or latest crop of all, British Queen, Premier, and Ne Plus Ultra. Early Peas, stick and protect against cutting winds, and

dredge with dry dust the base of all crops now up on dry evenings, to prevent canker and shanking.

Savoys.—Sow a full crop now, and then again at the end of the month.

Salsify.—Sow in drills 1 foot apart.

Scorzonera.—Sow after the middle of the month.

Seakale.—Sow in drills, or dibble 1 foot apart each way, in order to have strong plants for forcing next winter; if sown on well-prepared, pulverised, rich soil, and well attended to through the summer, strong clean plants will be the result.

Spinach.—Sow the round summer variety in drills, between Peas, or other ways, once a fortnight. Sow New Zealand Spinach in heat.

Turnips.—Sow in drills, a few, once a fortnight, of any small short-topped early kind, in order to have Turnips young, sweet, and tender.

THE LINNÆAN SOCIETY.

THE special general meeting of this Society, convened by the council to consider certain alterations in the bye-laws, was held on Thursday evening (March 5), at the Society's rooms at Burlington House, when the attendance of fellows was unusually large. Mr. George Busk, F.R.S., one of the vice-presidents, occupied the chair, and opened the proceedings with a conciliatory speech. He concluded with a suggestion founded upon a resolution of the council at its last meeting; that, if a committee, to be appointed by those who differed in opinion from the council, would prepare and forward to it a report embodying their objections, and suggesting any amendments in the bye-laws which might seem to them desirable, that report would receive the fullest consideration of the council. In order to meet fully this conciliatory suggestion, Mr. Carruthers formally moved, that a committee be appointed to consider the bye-laws, and suggest to the council such alterations as they might consider desirable. This motion was duly seconded by Mr. Dallas. As an amendment, it was moved by General Strachey, that, in lieu of this amicable arrangement, the opinions of some counsel of eminence should be taken as to the legality, or otherwise, of the recent alterations made in the bye-laws, and, in the event of such opinion being adverse to the council, steps should be taken to repeal such alterations accordingly. Contrary to what might have been expected, this amendment, which was duly seconded, appeared to meet with approval from the chairman; and, after an animated discussion, in which, however, we are glad to say, nothing of a personal or objectionable nature occurred, the amendment was carried by a considerable majority. A resolution, moved by Sir John Lubbock and seconded by Mr. Carruthers, was then carried, expressing the obligations of the Society to the late president, Mr. Bentham; and a vote of thanks to the chairman terminated the proceedings. As it transpired during the evening that the opinions of two eminent counsel had already been taken as to the legality, or otherwise, of the recent changes made in the bye-laws, which opinions were, in some respects, at variance, the proposal to submit to the opinion of a third may, to some extent, be of advantage. But, inasmuch as it is generally admitted that the whole of the existing bye-laws are in an unsatisfactory condition, which cannot be ameliorated by counsel's opinion on past proceedings, we think it is to be regretted that the suggestion of the council, as expressed by the chairman, was not accepted by the meeting, inasmuch as such an acceptance would have relieved the society of much embarrassment. The council assuredly took their defeat with complacency. The reason for this it is difficult to perceive, except upon the supposition that, subsequent to the meeting at which the resolution of the council, to which we have referred, and which was read to the meeting, was passed, they must have allowed themselves to be influenced by communications with the supporters of the amendment.

Plants as Weather Guides.—A writer in the *Field* says:—It is well-known that certain plants are very sensitive to changes in the atmosphere, and by their behaviour, the opening and closing of their leaves and flowers, serve as natural barometers to indicate the coming weather. A Prussian horticulturist—M. Hannemann, of Proskau—gives the signs he has found reliable with respect to the following plants. The small Bindweed (*Convolvulus arvensis*), and the Corn Pimpernel, or Poor Man's Weatherglass (*Anagallis arvensis*), expand their flowers at the approach of wet weather, whilst, on the other hand, the different varieties of Clover contract their leaves before rain. If fine bright weather is in prospect, the leaves of the Chickweed (*Stellaria media*) unfold, and its flowers remain awake and erect until mid-day. When the plant droops, and its flowers do

not expand, rain may be expected. The half-opening of the flowers is a sign that wet will not last long. The Burnet Saxifrage (*Pimpinella Saxifraga*), indicates the coming weather in the same manner. As to the small Cape Marigold (*Calendula pluvialis*), should it open at 6 to 7 a.m., and not close till 4 p.m., we may reckon on settled weather; if the flower continues sleeping after 7, it betokens rain. In the case of the Corn and common Sow Thistle (*Sonchus arvensis* and *oleraceus*), the non-closing of the flower-heads, warns us that it will rain the next day; whilst the closing of them denotes fine weather. Respecting the weather indications of Bladder Ketmia (*Hibiscus Trionum*), the Stemless Ground Thistle (*Carduus acaulis*), Marsh Marigold (*Caltha palustris*), Creeping Crowfoot (*Ranunculus repens*), Wood Sorrel (*Oxalis acetosella*), and other species of the *Oxalis* genus, rain may confidently be expected when the flowers of the first do not open, when the calyx of the second closes, and when the rest fold their leaves. We may also look for wet weather if the leaves of the Whitlow Grass (*Draba verna*) droop, and Lady's Bedstraw (*Galium verum*) becomes inflated and gives out a strong odour. Finally, the approach of rain is indicated in the case of the yellow Wood Anemone (*Anemone ranunculoides*) by the closing of the flowers, and in that of the Windflowers (*Anemone nemorosa*) by their drooping.

Castor Oil Seed.—The Castor-oil plant is extensively cultivated all over India. The oil is extracted by bruising the seed and then boiling it in water, the oil being afterwards skimmed off. This is the only seed out of which the oil is extracted by boiling, as, in this case, it is found cheaper than the method used for other seeds, which is by pressure. The cost of the seed is one rupee (2s.) per maund (about 56 lbs.), and the price of the oil is from two to five seers per rupee, according to the abundance of the crop in the season. The proportion of the oil yielded is about half the weight of the seeds boiled; it is only used for burning. In Cuttack, the plant is grown all over the province, a good deal in patches of newly cleared land in the jungles of the Tributary States and Sumbulpore. The oil is extracted in two ways. It is used for burning and culinary purposes, and, also, medicinally. Both the native methods of extracting oil are wasteful and tedious, and, therefore, expensive. European oil-presses, and a knowledge of some methods of clarifying the expressed oil, seem only to be required to render the oil-seed crops of this extensive division of great value. The large seeds of *Ricinus communis* major are employed for lamp-oil, and the small seeds of the variety *Ricinus communis* minor yield the medicinal castor-oil.

Paper Material.—Some of the American newspapers are now printed upon paper which is made from a reed-like Grass (*Arundinaria macrosperma*). The way in which this material is prepared for the manufacture by the Fibre Disintegrating Company would be too improbable for a hoax if it were not known to be a fact. The bundles of reeds are crammed into a metal cylinder, in which they are exposed to the action of steam at a high pressure, with which accordingly they become thoroughly permeated. They are then suddenly released, and, by the expansion of the steam, are not merely violently projected *en masse* against a sort of target placed to receive them, but at the same time are thoroughly disintegrated by the instantaneous dilatation of the compressed steam which has penetrated every part. A bundle of reeds is in this way converted into a disc of fibrous paper-pulp. There is something delightfully millennial in the utilising of artillery practice for literary purposes.

A White Coal.—Our antipodes, that fragment of the most ancient of existent Continents, that land of paradoxes, which would not allow the poor schoolboy his pet phrase of *rara avis in terris*, *nigroque simillima cygno*, but must fain turn out a black swan, make animals with birds' beaks (*Ornithorhynchus paradoxus*), and put the stones of Cherries outside of the fruit, has just revealed a new mineral—a white coal—which is fibrous, easily combustible, and burns with a light flame and no smoke. Nor is the material rare; large districts are covered with it, and it lies on or very near the surface. The coal is a species of lignite, and the colour is, most likely, due to the absence of bitumen.

The Tree of Knowledge.—There is in America a physiologist who, unlighted, perhaps, as to his intellect by the lamp of a fish diet, proclaims to mankind that Apples are the proper food, after all, of the sedentary brain-workers. The Apple, according to this observer, who obviously investigates things to the core, contains more phosphorous, or brain sustenance, than any other member of the vegetable republic; therefore, it is conducive to mental activity. This makes it clear that the Apple tree is, just as Eve thought, a "tree to be desired to make men wise." We can also now understand how it is that Apple sauce is always eaten with that foolish bird, the goose.—*Fun.*

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES ON PEAS.

THE recent publication in the columns of THE GARDEN of the combined reports on the Peas grown at Chiswick during the past two years, comes to us at a convenient time, and, not the least service rendered to growers by these reports is the way in which the varieties are classified, so that by reference hereto it is now easy to ascertain to what particular section of Peas any particular kind belongs. There are, however, some sections omitted that might have been added with advantage, such as early, medium, and late, and there would have been some interest attached to an arrangement of the whole number into dwarf, medium height, and tall; also, as to the comparative hardness, or otherwise, of the earliest Marrows, in contra-distinction to the old white or blue round kinds. This latter point is one of particular interest, as, now that we have Wrinkled Marrow Peas that produce a crop but a very few days later than Dillistone's Early Round, it is evident that the latter kind and its congeners must soon give place to the sweeter and better-flavoured Marrows, if these prove to be perfectly hardy. Of not less value would have been some practical information as to the difference in crop produced by a Pea that grows only 2 feet in height, and one that grows to a height of 6 feet. Gardeners have long favoured tall kinds, believing that these produce the heaviest crops, and probably where they do well, that is the case; but it must not be overlooked that all tall Peas grow to a height of from 3 to 3½ feet before they produce pods, and therefore seldom have, after all, a larger space of fruitful haulm than such kinds as grow only to that height. We are sometimes favoured with woodcut illustrations of tall Peas podding from the ground upwards, but everyone knows that such, in reality, is not the case. Some of our best dwarf Peas will, on the other hand, begin to bear pods very near the base of the haulm, and then they give quite as large a pod-surface as the best tall kinds do; then there is less danger of the haulm of dwarf Peas exhausting the soil, and becoming unproductive in dry weather, than is the case with tall Peas, which have so much more work for the roots to perform before a crop is borne. Another point of interest is the relative amount of support in the shape of sticks required by the two classes of dwarf and tall Peas, as Pea sticks are, in some places, dear and difficult to obtain. A few stout sticks will give support to robust dwarf Peas, but tall ones need assistance to keep them in proper position. There is another evil in connection with tall Peas, which has come under my observation, when grown in bulk together, viz., that when great heat prevails, so far from one row shading another, and thus promoting a cool temperature, the reverse seems to be the case, as the air between the rows, not being renewed by a quick circulation, becomes exceedingly hot, and the blooms suffer materially in consequence. Tall Peas should always be grown in rows several yards apart, with crops of Potatoes, Onions, or any other dwarf crops between them, and, under these conditions, a much better crop is obtainable than when grown in rows close together. Whatever may be the belief prevalent amongst gardeners as to the value, or otherwise, of dwarf Peas, it is, at least, certain that this section is eminently adapted for small gardens; nevertheless, in the face of this fact, tall Peas will continue to be largely grown. I have gone carefully through the Pea report and collated therefrom a list of twelve kinds, all of which are classed with the tall-growing sections, adding also their average height of growth and date of bearing pods fit for the table. The early section here do not exceed 4 feet in height, and are not tall in reality, but then they grow to twice the height that the earliest of the dwarf section do, and are, therefore, tall, by comparison.

Tall Kinds.

The whole of these Peas were sown on the same date, Feb. 23, and their successive periods of fitness spread over three weeks. They present a list of the very best of the tall

kinds, being, in all respects, good croppers, fairly hardy, and of the best quality. It is obvious that no one would care to make a selection of the whole dozen for any one garden, but, whilst some growers will favour a couple of the first earlies, others will prefer a different couple.

				FIT FOR TABLE.		HEIGHT.	
Dillistone's Early	June 9	...	3 feet.	
Sangster's No. 1	" 12	...	3½ "	
Easte's Kentish Invicta	" 13	...	3½ "	
Emerald Gem	" 13	...	4 "	
William the First	" 14	...	4½ "	
Prizetaker	" 23	...	5 "	
Paradise Marrow	" 24	...	5 "	
Laxton's Supreme	" 24	...	5 "	
Champion of England	" 25	...	6 "	
Ne Plus Ultra	" 29	...	6 "	
British Queen	" 30	...	6 "	
Tall Green Marrow	July 1	...	6 "	

Except in its particular earliness, Dillistone's Early is the least satisfactory one of the lot, as it is a poor cropper, but Sangster's No. 1 is a reliable kind, and William the First, although a day or two later, will beat it hollow, both for colour and quality. Kentish Invicta I find is this year being largely grown as a market Pea, a proof that it is a good thing, and I am much surprised to meet with it so seldom in private gardens. My impression of it, when seen at Chiswick, was greatly in its favour as an early Pea. Emerald Gem (grown at Chiswick both in 1872 and 1873), notwithstanding all that has been said about it, is a capital garden variety. All the others are too well-known to need further comment.

Dwarf Kinds.

Dwarf Peas present a wider, and, possibly, a richer field for selection, as there are few that are not good, and the bulk are excellent. There is here, also, no difficulty in selecting twelve sorts, all of which class as Marrowfats, even the earliest having, in this respect, the advantage of the earliest of the tall kinds, scarcely any of which have such excellent quality. I find the best here to be:—

				FIT FOR TABLE.		HEIGHT.	
Little Gem	June 16	...	1½ feet.	
Blue Peter	" 18	...	1½ "	
Nutting's No. 1	" 18	...	2 "	
First-crop Blue	" 19	...	2 "	
Multum-in-Parvo	" 19	...	1½ "	
Dean's Dwarf Marrow	" 24	...	2 "	
Princess Royal	" 25	...	2½ "	
Wonderful	" 26	...	3 "	
Fillbasket	" 26	...	3 "	
James's Prolific	" 30	...	3 "	
Omega	" 30	...	2½ "	
Veitch's Perfection	July 4	...	3 "	

The bulk of this selection can be grown well without the use of sticks or supports of any kind, and can be specially commended to persons who have town gardens, or reside where stakes and spray are difficult to obtain. The first half-dozen can be sown in rows at intervals of 2 feet apart; the remainder should have a space 6 inches wider. Grown in this way, they present no obstacles to the planting and growth of a winter crop of Cabbages or Kale; and, as soon as the Pea crop is gathered, the haulm can be pulled and the space between the rows of Winter Greens, either forked or deeply hoed through, and thus a second crop is well established, a result that could not possibly follow, were tall Peas grown. If I were about to grow any six kinds for succession in this list, I should select Blue Peter, Multum-in-Parvo, Dean's Dwarf Marrow, James's Prolific, Fillbasket, and Omega; and a selection of three for villa or small gardens would include Multum-in-Parvo, Dean's Dwarf Marrow, and Omega. Multum-in-Parvo is known as an improved Little Gem, as it has a larger pod and finer Peas. Dean's Dwarf Marrow has a remarkable robust erect growth, with branching habit. It represents a cross between Multum-in-Parvo and Premier, has fine pods, is exceedingly productive, and the Peas are of delicious flavour. Omega is the finest of all the late dwarf Peas, and presents one of the most serviceable forms that Mr. Laxton has raised. It has been well described as a dwarf Ne Plus Ultra, but more hardy; and higher praise could not well be rendered.

A. D.

NOTES OF THE WEEK.

— MR. JOHN WATERER'S annual exhibition of Rhododendrons will take place this year in Russell Square, Bloomsbury, instead of in the Royal Botanic Gardens, Regent's Park, where it has been so striking a feature for these last twenty-three years. The transference of the floral glories of Bagshot to one of the largest and best of our town squares is an event on which Londoners may congratulate themselves.

— MR. ANDERSON informs us that the first portion of the Meadow Bank Orchids will be sold there by auction on the 6th and 7th of May, and that at that sale will be offered some of the rarest and best specimens in the collection, which is well known to be one of the finest in Europe.

— It is proposed to present Mr. Abraham Stansfield, of Todmorden, with a testimonial, as an acknowledgment of the services which he has rendered to the cause of education and the advancement of science, particularly botanical science. The Todmorden Botanical Society owes its origin and continued success entirely to his unwearied efforts. A committee has been formed for promoting this object, in furtherance of which upwards of £50 has already been collected.

— NEAR Erigné (Maine et Loire), says the *Revue Horticole*, is a curious Oak about sixty years old, whose parent acorn was deposited, probably by some bird, in a cavity in the trunk of a Willow, at the height of about 8 feet from the ground. The young Oak, pushing its roots downwards, has since killed the Willow, of which very little now remains, while the roots of the Oak have obtained a firm hold in the soil. The singularity of the case is that the base of the Oak, for a height of nearly 8 feet, consists of a collection of roots, which are fast becoming covered with alburnum or sap-wood.

— WE observe that several lots of the new *Masdevallia polysticta* are to be sold at Stevens's on Monday next. Of this species Mr. Roezl says that when he first met with it at a certain distance off, he believed it to be *Odontoglossum nævium*, so much alike is the general appearance of the inflorescences of these two otherwise very different Orchids. The flowers have a light ground, richly dotted with dark purple, and are arranged in dense spikes. It is a free flowering graceful species of robust habit, and will form a striking contrast when associated with some of the high-coloured kinds.

— A VINE, says the *Boston Journal of Chemistry*, situated about three miles and a half from the town of Santa Barbara, California, has a trunk 4 feet 4 inches in circumference in the largest part. It begins to branch out at about 6 or 8 feet from the ground, and is then supported on framework, which it covers as a roof. The whole Vine thus supported now covers over an acre of ground. Several of the limbs are as much as 10 inches in circumference at a distance of 25 or 30 feet from the trunk. The annual yield of Grapes from this mammoth Vine is from 10,000 to 12,000 pounds. The clusters average, when ripe, from 2 to 2½ pounds each. This Vine, which is about forty years old, is on rather high ground, and, it is stated, that the soil about it has never been manured at all. This Vine, curiously enough, as in the case of Messrs. Lane's Vinery at Berkhamstead, has a small stream of water running near it, which probably assists its growth.

— WE have received from MM. Huber & Co., of Hyères, coloured plates of *Dahlia arborea*, a species quite distinct from *Dahlia imperialis*. In a circular, issued by MM. Huber, they say:—"It attains the height of about 7 feet, and forms a well-branched clump, with large leaves of a dark green, which contrast agreeably with the foliage of other plants. This inferiority of height makes it take up less room in the conservatory than the *D. imperialis*, and enables it to resist the wind better in the open air. From the end of December it produces an innumerable quantity of well-formed mauve-coloured flowers, the successive development of which does not suffer from a temperature below freezing point. The form of the plant is, moreover, quite new in the genus, for it can only be compared to a gigantic *Anemone*; and its peculiarity of flowering copiously at a low temperature is a rare occurrence among succulent herbaceous plants."

— FROM the report of the council of the Royal Dublin Society we learn that "For several years the state of the iron shed, used for the Museum of Botany, at the gardens, has been brought under the notice of the authorities. It is fast falling into decay, and, in a short time, will cease to be a sufficient protection to the interesting series of specimens temporarily placed there. The Science and Art Department, impressed with the importance of having a Museum of Economic Botany established in connection with the Botanic Gardens, succeeded in obtaining a grant from Parliament amounting to £4,000, for the erection of an appropriate building for the purpose, and, although the site was chosen, yet the Council failed to induce the authorities to take any step towards the erection of the building, and the vote was eventually withdrawn." A Museum of Science

and Art has recently been erected at Edinburgh, at a cost of nearly £90,000, but, it appears that an "iron shed, fast falling into decay," is considered good enough to form the Museum of Botany, which will supply instruction to the citizens of Dublin!

— THERE will, it is said, be no provincial exhibition this year in connection with the Royal Horticultural Society.

— MR. PEACOCK writes to us to say that *Agave univittata*, which we stated last week was throwing up a flower-stem at Kew, is also now showing for flower with him at Sudbury House, Hammersmith; it has grown a foot in three days.

— THE display of Persian *Cyclamens* at the Victoria Nursery, Holloway, where Mr. Williams has made this flower a speciality, is now quite striking. *Cyclamens* of this class must ever be favourites for greenhouse or conservatory decoration at this season of the year.

— MESSRS. MAULE, of Bristol, have sent us a coloured plate of a new Japanese Apple, named *Pyrus Maulei*. Of its origin we cannot speak, as Messrs. Maule have omitted to supply us with any account of it. From the appearance which it presents, however, as shown in the plate, we should think it a variety of *P. japonica*, with very spiny branches and almost spatulate leaves.

— THE *Charleston News* says, that the steamship "Manhattan," which left that port for New York February 25, had on board the first new Strawberries of the season, being a consignment consisting of about 100 quarts; she also took a parcel of new green Peas, both being among the earliest shipments known. They were the growth of Florida, and indicate that the semi-tropical climate of that state is able to furnish fresh fruits and vegetables nearly all the year round.

— THE extension of the *Cinchona* cultivation in Darjeeling continues. Every year additional land is brought under *Cinchona* culture and it is calculated that 2,000 acres more will be cleared and planted within the next four years. With regard to *Ipecacuanha*, upwards of 20,000 plants and cuttings are now in hand, all of which promise well. Another interesting fact relating to the introduction of useful plants into India, is that of the success in the Terai of the Cacao (*Theobroma Cacao*, L.). The plants that were planted out about a year ago, were sent from Kew at the suggestion of Dr. Hooker, and they are now in a most healthy and satisfactory condition.

— AT a meeting of the Royal Botanic Society, the other day, Professor Bentley delivered a lecture on the Fever Gum tree (*Eucalyptus globulus*). This tree, which is a native of Australia, grows to the height of 350 feet, and a plantation of it is exceedingly useful in sucking up and dissipating moisture from marshy land. The wood makes excellent building timber; the bark furnishes a powerful astringent, which is prepared in Australia in the form of lozenges and syrup. A preparation, known as eucalyptol, is efficacious as an antiseptic, stimulant, and disinfectant. Gums are obtained from it, and among other unexpected uses it is employed for flavouring soup and making cigarettes, which afford alleviation in asthma. It has been successfully cultivated in many parts of the world, but the climate of England is not favourable to it. Sixty plants of it were planted in the Royal Horticultural Society's Garden at Chiswick in the spring of 1847, the plants being two years old and 3 feet in height. They grew rapidly, and were not in the least injured by the winters of 1847-8 and 1848-9, but were totally destroyed by the severe frost in January, 1850, when they had attained a height of from 18 to 25 feet. All, too, suffered alike.

— SCOTLAND is said to be, year by year, becoming less productive in the matter of fruit. At a meeting of the Botanical Society of Edinburgh last week, Mr. McNab read a paper on "Further evidences of Climatal Changes in Scotland," and mentioned that several old Scotch gardeners, as well as amateur cultivators, concurred with his opinion that many varieties of fruit now cultivated in that country were by no means equal to what they were from thirty to fifty years ago. Ribston Pippins and Nonpareil Apples are alleged to be inferior in size and flavour as well as number to the specimens formerly seen. The Jargonelle Pear, once extensively grown and thoroughly ripened on standard trees in various districts of Scotland, is now exceedingly scarce. The famous Carse of Gowrie orchards, which half a century ago were so remunerative, and in which seventy varieties of Apples and thirty-six varieties of Pears were cultivated as standards, still exist, but with a sadly diminished production of fruit. The Clydesdale orchards are in the same failing condition. The Damson shows signs of becoming extinct, and the common Black Sloe and Bramble Berries are in like manner on the decline. From the old minute books of the Caledonian Horticultural Society, it appears that from 1810 they offered prizes for Peaches grown on open walls without the aid of fire flues; but, after 1837, these were discontinued, and the generality of the competition Peaches sent are grown on flued walls or in Peach-houses. Similar evidence was given with regard to Cherries, Gooseberries, and Scotch-grown American Cranberries, and even the Filbert and Hazel Nuts are, it is stated, not by any means so flourishing as formerly.

THE FLOWER GARDEN.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Crustacean Group.

THERE is, perhaps, hardly a single genus of plants that presents so great a diversity of aspect as the Saxifrages. Hence, it is not at all surprising that the uninitiated seem somewhat dubious, when you assure them that our common Mossy Saxifrages and the old London Pride are so intimately related as to come under one generic title. How much greater then must their astonishment be, when you further assure them that the same slender-leaved trailing plant is related, in an equal degree, to *S. crassifolia*, that coarse-looking species usually consigned to the back settlements of old shrubberies? not that I wish, for a moment, to disparage even it, though its leaves put one a good deal more in mind of a Rhubarb than a Moss; yet, this is really the case, and, what is more, they possess such well-marked structural peculiarities in common, that, though separate generic titles have been given to the more important groups, the old genus *Saxifraga* reigns supreme, and holds its head high above the influence of any revolutionary monographs that may be published. The question then, naturally, arises are we to endorse the monopoly and stick to the old patronymic? or, are we to resuscitate the sectional genera, such as *Robertsonia*, *Boykinia*, *Bergenia*, and others? For my part, I am, in this case, decidedly disposed to be conservative, and purpose retaining the old familiar title of Saxifrage, which, being literally interpreted, means "stone-breaker," an admirable title, by the way, as, growing amongst rocks and spreading over the surface of large masses of stone, they insert their delicate roots into every crack and crevice, thus assisting, materially, in the slow, but sure, eroding process by which the hardest rocks are transformed into the first elements of soil. Taking then the genus *Saxifraga*, as our text, it will be obvious that it naturally divides itself into groups, and under the following groups we shall consider them. Thus we have the Crustacean, including all those with silvery cartilaginous excretory formations occurring on the margins of the leaves; the Mossy group, of which our own native *S. hypnoides* may be taken as the type, forming cushions of bright-green foliage; the ligulate, or ciliated, group, with large fleshy leaves producing their rosy flowers in dense panicles, of which *S. crassifolia* is the type; the London Pride, or None so Pretty, group, with which all are familiar, and for whose typical representative we shall take *S. umbrosa*; the sarmentose group, with their long straggling runners and prettily-marked foliage, of which we can select no better representative than the *S. sarmentosa*, or Wandering Jew; the opposite-leaved group, whose lovely crimson flowers are amongst the earliest of the whole family, for which no better sponsor can be found than *S. oppositifolia*; and finally a somewhat heterogeneous assemblage that we shall call the yellow-flowered group, of which we may take *S. aizoides* as typical.

Pyramidal Saxifrage (*S. pyramidalis*).

Having thus enumerated the several groups under which I purpose passing in review the various well-defined species of Saxifrage that are at present in general cultivation, I am quite sure no one will challenge me with attempting a botanical memoir; I merely take their outward characteristics, and deal with them from a popular, not a technical, point of view. I may as well, at the outset, state that I once wrote a monograph on the genus, viewing it from a sort of combined botanical and horticultural stand-point, but a long experience in raising Saxifrages from seed has sadly shaken my faith in the matter of specific distinctions, and I see, in the elaborate monograph recently prepared by Dr. Engler, of Breslau, that most of the fifteen groups into which he divides the genus are supplemented with a list of hybrids, or presumed hybrids, which lists might, in truth, be largely increased. To anyone who is desirous to go thoroughly into the botanical characters of all

the described species of Saxifrages, the doctor's monograph will be found invaluable. Though I gladly avail myself of it as a sort of text-book in the matter of nomenclature, I may say there are points, and those not a few, in which my practical experience will not permit me to endorse the ruling of the learned doctor. The Crustacean group, which I have selected as the most appropriate to begin with, commends itself for the premier position by the very fact that to this group belongs the veritable Queen of Saxifrages—*S. longifolia*. No one who has seen the plant in vigorous growth will begrudge it the regal dignity which it so well deserves, but the mere mention of this species must suffice at present, seeing that I take as the typical plant of this section *S. pyramidalis*, so admirably delineated in the accompanying illustration. It will be recognised by many as an old friend and favourite. Usually speaking, it is said to be synonymous with Linnaeus's old *S. Cotyledon*, but I have a decided notion that these two names really belong to two distinct species, or, if not, that the former is, at least, a well-defined variety of the latter, giving, of course, precedence to the older name. Wherein, then, rests the distinction? Let us briefly compare their general characteristics. In *S. Cotyledon* the individual radical leaves, that form the large rosette which precedes the blooming process,

are slightly glaucous and somewhat grey in colour; they are scarcely obovate, whereas, in the pyramidal plant, they are markedly obovate, and of a very deep green; the floral axis, which, terminated by the first expanded bloom, constitutes an admirable illustration of the form of inflorescence known as a compound cyme, rises to a height of 2 to 3 feet in the former whereas, in the latter, it rarely exceeds 18 inches; the true leaves, though somewhat modified in size, being, in this case, continued up the stem for a considerable distance. The secondary branches of the inflorescence of *S. Cotyledon* are erect, and they, as well as the primary axis and calyxes, are green in colour, whereas, in *S. pyramidalis*, the floral branches are drooping, and the whole of the stalks are covered with purplish glandular hairs. The calyx, also, has a crimson tint, and the flowers have narrower petals, and a far greater purity of whiteness. Another important distinction consists in the fact, that, whereas *S. pyramidalis* seeds freely, I have never yet

succeeded in getting perfect seeds from *S. Cotyledon*. The distinctions I have enumerated may appear somewhat trivial, but they are wonderfully constant; and, further, an excellent authority, who has seen the two species growing side by side on the Swiss Alps, informs me that their distinctive characteristics are even more marked in a state of nature than under cultivation. Engler, I see, admits that there is a form of *S. Cotyledon* with purple hairs and most abundant flowers, which form is, no doubt, the same as our *S. pyramidalis*. Be they, however, species, varieties, or mere forms, they are both worthy, in the highest degree, of being cultivated—nay, more, of being well cultivated—and amply will they repay the extra attention bestowed on them. Occasionally, they may be seen under ordinary rock-garden treatment, producing large and perfectly pyramidal cymes; for, be it noted, the pyramidal character is common to both, but, if you want to grow them to perfection, give them the benefit of liberal treatment. No better place for the experiment can be selected than the sunny south border of a kitchen garden, rich in all the good things for plant life, as such borders usually are. Let such portion as you purpose devoting to Flora—*versus* Cauliflora—be on a dry spring day, well trodden down and consolidated; select the strongest off-shoot rosettes from the parent plants, such as show no indications of bloom any time during the latter part of March or beginning of April; plant these in rows, at distances of 15 inches apart, and 12 inches in the row. A little water and attention may be requisite till they get root-hold of the soil; having done this, by the autumn you will find they have formed rosettes, 9 inches or more across, and, possibly, in some cases, a considerable number of offsets as well; these, however, should all be carefully removed, so as to concentrate the entire energies of the plant into the blooming rosette. Leave them during the winter following fully exposed, and by the month of May you will be enabled to realise, to perfection, the beauties which both species are capable of affording. Pyramids of blossom will result from each rosette with a regularity of outline and symmetry of shape that once seen are never to be forgotten; and, if the two forms are cultivated in this way, under exactly similar circumstances, you will be able to draw your own conclusions as to whether I am correct in my surmise, that *Saxifraga Cotyledon* and *S. pyramidalis* are distinct species, or the same. I venture to think, without hesitation, you will adjudge them as being, if not distinct species, at least worthy of distinct names. Geographically speaking, both plants have a wide European range, and are met with in abundance on the Swiss Alps, on the mountains in Dalmatia and Carinthia, in Lapland and Norway, even as far west as Iceland, the only instance in which they are recorded as occurring beyond the bounds of their European home.

HALF-HARDY SUCCULENTS.

(PACHYPHYTUMS.)

PACHYPHYTUMS are fleshy-leaved plants, suitable for green-houses, frames, or windows, or for flower-garden decoration in summer, where they have a striking effect, either grouped with other succulents, or used as carpet-bedding plants. They may also be usefully employed as edgings to small beds containing plants of a low-growing character. They will endure a degree or two of frost without injury, if previously well-hardened, but it is safest to take them indoors about the middle of October, or thereabouts. When taken up, after removing a few of their lower leaves, pot them a little deeper than they previously stood in the flower garden, and use for the purpose as small pots as will conveniently hold the roots. This has a tendency to keep them dwarf. It matters little even if the old roots are considerably reduced in this operation, as fresh ones will be thrown out freely from the portion of the stem that is buried. During winter, keep them on the side of dryness, rather than wet. A good loamy soil mixed with some pounded brickbats suits these plants when lifted better than rich material. The leaves taken off when the plants were lifted from the open ground may be used as cuttings. Get some clean pans or 4-inch pots, drain them well and fill them up with sandy loam mixed with some finely-ground brickbats, and, around the edges of these pots or pans, insert the leaves thickly

and firmly; also, fill up the central space with them, but not thickly. In preparing the leaves, cut them clean across at the base with a sharp knife, and then spread them out on a shelf, where they will not dry too quickly, but where their ends will become, to some extent, healed over. I have seen such leaves lie about in this manner for a fortnight, and then, when their ends were inserted in soil, roots were soon emitted. If the leaves were inserted in soil immediately after being removed from the parent plant, they would probably all rot off at the base. At one time leaf-cuttings of succulents used to be treated as follows:—After the cuttings were made they were inserted, top downwards, in sandy soil, merely keeping the cut part above ground, in order that it might become well dried, and, consequently, not apt to rot; they were then lifted out and inserted in the proper manner. In this way a well-dried cut end was secured, and shrivelling from evaporation was prevented. There is no necessity, however, for treating *Pachyphytums* so carefully, as they do quite as well when dried—as has been mentioned—on shelves or stages. When the cuttings have been put in, the pots containing them should be placed on a shelf as near the glass as possible; they should be kept only moderately moist, free from drip, which is destructive to them, and never shaded unless the sun shines very brightly. They should be frequently looked over in order to remove any portions that may happen to be damping off, and, if the temperature of their winter quarters be a few degrees higher than 40°, they will form eyes much sooner than they otherwise would do, and be nice little plants before spring. In February, pot the strongest of them in thumb-pots, and prick off the others about 2 inches apart into boxes, and, if convenient, place them in an intermediate house till April, and they will form good plants for bedding-out the first year. Such warm quarters, however, are not necessary; for a dry frame would suit them quite as well. In that case, however, the plants would be too small for use in the flower-garden during the coming year. *Pachyphytums* may be increased, by means of leaves, at any season; but from February to October is the best time for that operation, and for that purpose good, well-matured, and firm leaves should always be chosen. If struck in spring, a little shading will be necessary in bright weather, and they should be potted or pricked off as soon as good young plants are formed. In this way, strong plants may be secured for next summer's outdoor display. *Pachyphytums* may also be raised from seed; indeed, this is the readiest mode of increasing them, and the one attended with least trouble. The seeds should be sown in autumn, as soon as they are ripe, or in the succeeding spring; but, if delayed longer, they come up badly, some being ready to prick off before the others have germinated. For seeds, prepare pots or pans filled to within 2 inches of the surface with crocks, then with sandy loam and very finely-crushed crocks or bricks; sow regularly, and rather thinly; cover slightly with a finely-sifted portion of the soil, and place a pane of glass over the surface of each pot. Place the pots in an intermediate house, near the light, and shade well until germination takes place, after which gradually inure the young plants to light; let the pane of glass be tilted up a little, and after a short time let it be entirely removed. The seedlings will soon gain strength and burst into the rough leaf, when they should be pricked off into other pots, pans, or boxes, and finally potted singly. If the produce of autumn-sown seeds, it is safest to keep them in the seed-pots till spring; but, if spring-sown, prick them off as soon as they are large enough for handling. For seed-bearers, the tallest plants should be chosen, divested of many of their base leaves in autumn, kept as dry as is consistent with their safety in winter, and started into growth in spring. This invariably induces them to flower, and that early, which is advisable, as the seeds have, in that case, a better chance of ripening in perfection than they otherwise would have. Flowering plants should be kept in pots, indoors, in a dry airy house, and the seeds, when ripe, should be gathered and spread out to dry. When grown in pots in summer, and used for conservatory decoration, some rotten manure should be mixed with the soil. *Pachyphytum bracteosum*, or "Silver-bracts," a striking plant with silvery leaves, forms an excellent subject for the centres of raised circular beds during the bedding season.

WM. FALCONER.

BROMELIA-LEAVED SEA-HOLLY

(ERYNGIUM BROMELIÆFOLIUM).

THIS is a very interesting plant, and one of the most distinct and striking of this attractive family. It forms a dense Yucca-like tuft, composed of numerous, long, channelled leaves, margined with slender spines. The radical leaves are from 2 to 3 feet in length, and the plant, without the flower-spike, is about the same height. The flowers are whitish, and not so showy as many others of the family; but the graceful habit and elegant foliage of the plant entitle it to a place in every collection. It is a fine subject for the sub-tropical garden, for dry commanding positions on rock-work, for ordi-

Bromelia-leaved Sea-Holly (Eryngium Bromeliæfolium).

nary borders, or as an isolated tuft on lawns. It is perfectly hardy, and an easily grown perennial. A. J. PERRY.

Culture of Ixias, Sparaxis, &c.—Grown under glass, these flower in March and April; out-of-doors, in May, June, and July. They are amongst the most graceful, attractive, and beautiful of Cape flowering bulbs. They differ considerably in style and habit of growth, but, being closely allied, they require the same cultural treatment. For in-doors, plant, from September to December, five or six bulbs in a 5-inch pot, using a compost of turfy loam, leaf-soil, and a little silver-sand. Make the soil firm about the bulbs, then place them in a cold pit or frame, plunging the pot in ashes, and withhold water till the plants appear, then give sparingly at first. The lights should not be kept on except during very wet or frosty weather. Early in March, when the plants have made some growth, they may be removed to the greenhouse, or where there is a very gentle warmth, and placed on a shelf close to the glass till in bloom. For out-doors, choose, if possible, a light loamy soil, thoroughly drained, and with a due south aspect; if backed by a wall or greenhouse, all the better. Plant the bulbs from September to February, at a depth of from 4 to 6 inches, and 1 to 3 inches apart. The early plantings must be the full depth, and the later plantings need not be covered quite so heavily. As the roots should be kept as dry as possible during winter, the early plantings must be protected either with litter, or with 2 or 3 inches of dry leaves; or the beds hooped over and protected with mats. The January or February plantings seldom require protection.—P. BARR.

Pelargonium Endlicherianum.—I have some doubts as to the general hardiness of this Pelargonium, of which an interesting notice appeared in your columns the other day. I have grown it for

several years, and it certainly will not stand the winter here. It flowers freely, but does not ripen its seed with me. I do not find it easy to strike from cuttings, which are apt to damp off. I have at present only one old plant of it. I find the same difficulty in propagating another interesting plant belonging to the same family, viz., *Erodium incarnatum*, of which I am seldom or ever able to preserve more than one plant through the winter. Cuttings of this strike freely, but, when potted, damp off. Can anyone supply me with a small plant of *Erodium pelargoniflorum*? I have hitherto failed to procure it. Messrs. E. G. Henderson's foreman, Mr. Jennings, has often told me of a very beautiful *Erodium* with large yellow flowers, which they once had under the name of *E. olympicum*, but was soon lost. What was this? and where did it come from? Could it be the same as *E. chrysanthum* of Boissier's "*Flora Orientalis*." Has anyone ever grown *E. gruinum* of the same author? which, from his description, must be a very beautiful plant. Has anyone now the true *Geranium Lambertianum*? It is not so beautiful as its congener—*G. armenum*—but still a most desirable plant. Some six years ago, I saw it growing luxuriantly in Lord Rathdonnell's Garden, at Green Mount, Co. Louth, and also at Glasnevin. I have not seen it since. Does anyone now grow those two lovely plants—*Monsonia speciosa* and *lobata*?—H. HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring*.

Worm-casts on Lawns.—These are often troublesome, especially during wet weather. I am of opinion that their entire eradication is impossible, but they may be kept in check as follows:—Sweep the lawn with a birch or other rough broom, so as to disperse the casts, then strew the surface with common salt at the rate of eight bushels to an acre, choosing a moist day for the operation. Less than eight bushels would do good, and a bushel or two more would do no harm. This dressing not only banishes the worms from the surface, but, when used in the quantities just indicated, it has a beneficial influence on the Grass. The salt may be dissolved in water, and applied in a liquid state, but the labour and waste of time thus incurred are needlessly spent, as no better results are experienced by this method than when common dry salt is employed. Six bushels of salt and six or eight of soot well mixed together, and applied either in a liquid or solid form to a lawn of, say, an acre in extent, is not only an invaluable safeguard against worm casts, but is, also, a good dressing for the Grass; even soot alone, applied at the rate of from twelve to sixteen bushels to the acre, is equally serviceable for both purposes. Air-slaked lime, used at the rate of from twenty to thirty bushels to the acre, or mixed with soot, or salt, or both, also forms a good dressing, especially for Mossy lawns, and it likewise destroys worms and grubs.—Q.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Hardiness of Alpine Plants.—I have lost several of my Alpine plants this winter, owing, as I believe, to the absence of snow, which forms their natural protection from frost and cutting winds on their native mountains. On the other hand, my herbaceous plants have not suffered in the least. Is the supposed greater hardiness of the former, because they are found at high altitudes, really to be explained by the fact, that they are always effectually protected in winter by a deep warm covering of snow, which only disappears under the hot sunshine of the advanced spring?—W. E., *Leek*.

Night-scented Stock (*Matthiola tristis*).—Can you tell me where this deliciously-scented flower can be had? What is its mode of culture and duration? I met with it once at the gardens at Wardie Lodge, but since then have looked for it in vain in seedsmen's lists; besides having lost a few offsets which were kindly given me at Wardie.—SALMONICERS. [We are not surprised that you have failed to meet with this plant in seedsmen's lists. It is increased only by means of cuttings, and is really a frame suffrutescent species, possibly hardy on dry rock-work or walls. It may, we think, be had of the leading London nurserymen, and, though not common, is less rare than you seem to imagine.—ED.]

Portulacas.—The single Portulacas, in brilliancy, delicacy, diversity, and beauty of colour, surpass all other out-door plants, thriving where most other plants get burnt up. They delight in sunny situations and light soils, rapidly carpeting the ground with flowers and foliage. They are quite at home on rock-work exposed to the sun, on stumps of trees, in rustic vases, on banks, and wherever plants of a spreading or drooping habit are required. The double Portulacas are of the same brilliant and diversified colours as the single. Their saucer-shaped flowers being filled with petals, greatly enhance their general effect, so that wherever beds can be formed of these, they will surpass in brilliancy all other dwarf bedding plants.—P. B.

Night-blooming Hardy Plants.—The following enumeration of hardy plants, which bloom only during the night, appears in a late number of the *Belgique Horticole*, viz., *Mesembryanthemum noctiflorum*, *Silene nocturna*, *Gladiolus tristis*, *Pelargonium triste*, and *Hesperis tristis*. The flowers of the three last-named plants are usually of a dingy-yellow colour. The *Marvel of Peru* (*Mirabilis Jalapa*) and the long-flowered species (*M. longiflora*), both begin to unfold their flowers at sunset. Another, now little known, although old-fashioned, night-bloomer, is the *Petunia longiflora*, an annual from Chili, which bears an immense corymb of large tubular pure white flowers. The Evening Primroses complete the list; and, of these *Oenothera biennis*, *O. longiflora*, and *O. stricta*, are mentioned as particularly deserving of notice.

THE INDOOR GARDEN.

TENDER BULBS FOR SPRING-FLOWERING.

BULBOUS plants are among the most useful of all flowering plants, as their general culture is of the simplest possible description, and many of them, as the Amaryllises, may be dried off for a considerable period, and can then be forced into bloom any time, as required. Many of the bulbous plants bear very large and richly-tinted flowers in great abundance, and these are useful for cutting and arranging along with fresh green foliage in the drawing-room vases. Amaryllises are especially adapted for the latter purpose, their bell-shaped flowers being of great substance, and, in most cases, gorgeously coloured. We have a whole host of varieties of Dutch bulbs that flower at this season, such as Hyacinths, Tulips, Crocuses, and Jonquils, but, at present, we propose to deal with a few less common species that are, nevertheless, equally well adapted for culture in the greenhouse or plant-stove.

Eucharis amazonica.—This is, in all probability, one of the finest and most generally useful of all stove bulbs when well-grown, and it can be had in bloom every month of the year, with but little difficulty. It is readily propagated by means of off-sets, which are freely produced by established bulbs, and these, if potted separately in a rich sandy compost, in their turn soon make strong-blooming plants. A good compost for this plant is one composed of half fibrous peat, a quarter leaf-mould, or rotten manure, and a quarter coarse well-washed river-sand. The pot should be thoroughly well-drained, and the plant liberally watered when growing. When the pot becomes filled with hungry roots, a little weak manure-water is an excellent stimulant. It is a plant that requires growing on rapidly, and then resting for a week or two in a dry sunny house, in order to induce it to bloom freely. By resting, we do not mean that the plant should be starved until the leaves fall; this would ruin it, for one season at least. When liberally treated in a warm moist stove, plants of this charming exotic will bear two or three crops of flowers every year. Some growers plunge the pots in a warm bed of tan when the plants are making their growth, and this helps the formation of roots very considerably; frequent syringings are very beneficial to the growth and fresh appearance of the foliage. These flowers are even more valuable than white Camellias, for cutting either for bridal bouquets or vase decorations, while, for ladies' hair, they are unrivalled even by the chastest and purest of white Orchids.

Griffinia parviflora.—This is a pretty little evergreen bulb, having leaves somewhat like those of the Eucharis in shape, but beautifully netted with dark green. It bears clusters of bright blue flowers on scapes 5 or 6 inches high, and is a very ornate stove-plant, well worth growing for variety in every collection. It does well in a light, rich, well-drained compost.

Amaryllises.—These plants ought to be universal favourites in every garden, as they are very readily grown, while the flowers of some varieties are most gorgeously coloured. Nearly all the varieties are deciduous, and may be dried off for months together, so as to take up but little space. The great point in their successful culture is to induce them to grow vigorously immediately after flowering, so as to get the bulbs plump and well-ripened for the next season's bloom. We have the following showy varieties now in flower, viz:—*Amaryllis vittatum* var. *Harrisoniæ*, a profuse bloomer, and one which bears numerous long Lily-shaped flowers of a creamy-white, each segment having two bold crimson stripes down its centre, while its scapes bear more flowers than the other varieties; *A. Ackermanni pulcherrima*, one of the finest of all the varieties, bearing a fine bold flower of the deepest velvety crimson imaginable, and should be included in every selection of these beautiful plants; *A. Le Zouave*, a bright reddish-crimson variety, profusely speckled with white, distinct and bright, well worth growing; *A. Spotted Gem*, creamy-white, speckled with vermilion; *A. Ariadne*, a very beautiful and distinct form, bearing pure white flowers, heavily streaked with crimson; *A. Leopold*, a very large fully-expanded flower, of a creamy-white colour, the lower parts of each segment being of a rich maroon-crimson; *A. Sultana*, a crimson-streaked kind of great size and substance. Besides the above, there are at least a hundred other varieties and seedlings, which, carefully raised, often turn out remarkably handsome for ordinary purposes of decoration.

Crinum amabile.—This is a stately species, almost worth growing for its bright green foliage, apart from the beauty of its flowers. The latter are borne on tall scapes, and are as large as those of the common White Lily; but even more beautiful, being delicately tinted with soft flesh-colour. This, and all its congeners, grow well in a compost of fibrous loam, leaf-mould, and sand.

Pancratium fragrans.—This is a robust plant, bearing long-

petalled white delicately-perfumed flowers, on scapes 1 foot to 15 inches in height. It has thick leathery foliage, of a deep green tint, and flowers very freely. Like the Eucharis, it blooms at different periods of the year; and, if a dozen plants are grown, their flowers will be found very useful for the centres of bouquets, or other floral decorations. They like a hearty compost of fibrous loam and well-rotted manure or leaf-mould, while a little weak liquid-manure is very beneficial when the pots become filled with roots.

Triteleia uniflora.—This is not a tender bulb; on the contrary, it is perfectly hardy; still, it is one of the prettiest of all greenhouse pot-plants at this season of the year, and, together with its blue-flowered narrow-leaved variety (which is generally met with under the name of *Leucocoryne alliacea*, the specific name being given in reference to its evolving a strong odour of Garlic when bruised), the plant requires no special treatment. Bulbs potted in the autumn flower regularly in the following spring.

Urceolina pendula.—Of all stove bulbs this is one of the most graceful, but, unfortunately, it is deciduous, and its elegant canary-coloured drooping flowers are borne before the glossy green foliage makes its appearance; still, the drawback can be remedied to a great extent by associating it, when in bloom, with fresh Palms and Ferns.

Imantophyllum miniatum.—This is an excellent subject either for the greenhouse or conservatory, its fresh green foliage being always interesting, even when the plant itself is not in bloom. It flowers very profusely when thoroughly well established, but, like most other bulbs, the pots must be well filled with roots before it will make any effort to bloom. The flowers are of a bright orange tint, borne on stout two-edged scapes just above the deep glossy leaves. A few plants of this should find a place in every good collection, however select. B.

HYBRIDISING ZONAL PELARGONIUMS.

By Dr. John Denny's article in *THE GARDEN* of 7th February, and that of Mr. Laxton, of 14th February, I am invited to answer certain questions respecting the hybridisation of Zonal Pelargoniums. I am very willing to reply, as far as lays in my power, and I am the more disposed to do so, as I am of opinion that horticulture, as well as all other arts and sciences, can be benefited by the international and friendly communications of all those who have the same devotion to progress.

Aline Sisley is, as Dr. Denny supposes, an isolated result out of many seedlings from the same cross. The seeds (seventeen in number, of which only eleven came up) were sown the 16th January, 1872. The mother-plant originated from Madame Vaucher, impregnated in 1869 by Gloire de Nancy, which produced single whites. These were again impregnated by Gloire de Nancy, and, till 1871, produced single whites, and a few pinks (also singles). I kept these seedlings, and, in 1871, impregnated one of the single whites with a double red of my own raising, which, also proceeded from Madame Vaucher, fecundated, in 1868, by Triomphe de Dumesnil (double red), and, in 1869, produced a single white, which was, in 1870, impregnated by Cottington (semi-double red), and produced, in 1871, this double red, the father of Aline Sisley; mother and father being, thus, grandchildren of Madame Vaucher. Out of the eleven seedlings of 16th January, 1872, I lost four. The seven remaining were:—One double white (Aline Sisley), two single white, one single pink, one double pink, two semi-double cherry.

Till then, Madame Vaucher had repeatedly produced single white, although fecundated by double red; and several horticulturalists here have told me, that they have not been able to obtain a double flower from her. As to the raising of Gloire de Nancy by M. Victor Lemoine, by impregnation of Beauté de Suresnes by Auguste Ferrier, there can be no doubt, M. Victor Lemoine being a most honourable horticulturist, and made no mystery of it when he sold it in 1865. As to the difficulty of crossing Beauté de Suresnes with any other variety, I have experienced it myself, although I have persevered in the attempt for the last five years. To ascertain whether this difficulty was general, I have written to MM. Victor Lemoine and Crousse, of Nancy; Emile Chaté, of Paris; Bruant, of Poitiers; and Cassier, of Suresnes. The latter, who is the raiser of Beauté de Suresnes, answered, that he obtained, in 1856, a pink Zonal, which he named Roseum nanum, and which produced in 1858, Madame Cassier. In 1862, Madame Cassier produced Beauté de Suresnes, which, again produced, in 1866, Surpasse

Beauté de Suresnes. All these were raised without artificial fecundation.

The four other horticulturists replied that they have never experienced any difficulty in fertilising Beauté de Suresnes with the old double varieties, Auguste Ferrier and Martial Champflour, and also with their offspring Gloire de Nancy and Madame Lemoine, and that it was from Beauté de Suresnes that they have obtained all their double pinks and reds. They also say, that if I, and other cross-breeders, have not succeeded, they think that we do not possess the true Beauté de Suresnes, and, M. Cassier is of opinion that we possess Surpasse Beauté de Suresnes, which is very shy in producing seeds. All this is very likely, but may proceed from other causes, and, probably, from the male parent chosen by Dr. Denny and myself; for my own part, I have constantly fecundated Beauté de Suresnes with doubles of my own seedlings; and, I am the more disposed to think this to be the cause of my failures, that Boule des Hespérides, which produced with me a great number of double varieties like Victoire de Lyon and Charles Darwin, refused last year to be impregnated by my new double whites, salmons, and other yellowish shades, although I operated on more than twenty plants. This seems to show that some plants of the same family are not congenial, and have dislikes. The consequence of all this for me is, that there are great uncertainties and mysteries, which I do not feel myself competent to solve. I have not yet found a criterion to guide me or a rule to follow. The only thing, I think, beyond doubt is the influence of the male parent; and I, therefore, have, till last year, always impregnated single flowers by double ones, to obtain new double varieties. But, as I also think that to all rules there are exceptions, I last year changed my proceedings, and fecundated singles by doubles, doubles by singles, and doubles by doubles. I will publish the result next autumn. My only rule (if it may be called so), is to suppress all the old single varieties, when I find among my seedlings one equal to them. Amongst about 200 single varieties I grow to obtain seed, I have only kept, of the old varieties, Beauté de Suresnes, Jean Sisley, Oracle, Darkness, Mina Hahu, Corsair, Donald

Beaton, Crimson Nosegay, Virgo Maria, Madame Vaucher, White Tom Thumb, Tricolor, Marie Mézard, Alba grandiflora, Eugène Buenzod, Lady Cullum, Boule des Hespérides, Arlequin, Madame Jules Smith, Chant National; and, amongst those with double flowers, Gloire de Nancy and Madame Lemoine. All the others are new seedlings of my raising.

As to the existence of a double Zonal Pelargonium in Belgium about fifty years ago, I have written to M. Louis Van Houtte, and M. Edward Morren, but they know nothing about it. Respecting Rose-Charmeux, it has proved that all sports have a tendency to reversion. I suppressed it two years ago, because it had become quite single. I do not know the origin of Cottington, but am disposed to think, like Mr. Laxton, that it is also a sport, because for the last two years it has produced with me nothing but single flowers. I hope that I have replied satisfactorily to the questions of Dr. Denny and Mr. Laxton. If not, I am quite at their disposal for any other information they may require.

JEAN SISLEY.

Lions.

Eucharis amazonica.—One small house at Eaton Hall is entirely devoted to this lovely plant, and the display made by it is simply magnificent. When I saw it, the other day, no fewer than 437 spikes were in full beauty. The plants were plunged in beds on

each side of the pathway, thirteen plants being on each side. Another house is also devoted to the culture of this useful plant; but, in this instance, it is grown in small pots, for decorative purposes. Here I counted 330 spikes, four and five being on each plant in an 8-inch pot, and one which I noticed, in the same sized pot, was bearing six spikes. I also learned from Mr. Selwood, the gardener, that this was the second time of flowering this winter; the same plants, large ones, having thrown up 380 spikes, and, small plants, 221 spikes, in the latter end of October and the beginning of November last, making a total of 1,368 spikes during the season, averaging five flowers on a spike. These have furnished an abundant supply all through the winter.—A VISITOR.

THE WINGED SPLEENWORT.

(ASPLENIUM ALATUM.)

THIS, by no means an uncommon species in collections, grows freely in an ordinary plant-stove treated like its congeners. When well developed, it produces a vasiform tuft of fronds which measure, individually, from a foot to 18 inches in length, and are of a pale green tint, in some cases almost glaucous. This variety is very suitable for a hanging basket or Wardian case. The accompanying illustration, though much reduced in size, is a faithful representation of a plant of it which we lately saw in Mr. Williams's Nursery at Holloway. It is a native of tropical America, and should be included in every collection, however small, of stove Ferns. G.

The Winged Spleenwort (*Asplenium alatum*).

Phalænopsis Schilleriana.

—This magnificent plant is the finest of the genus, and requires the treatment of Epiphytal East Indian Orchids. One characteristic of this species, which is not peculiar to any of the others, is, that if the flower-spikes are pinched out before the blooms are expanded, in the hope that they will, eventually, reproduce them a little later, disappointment will be the result. *P. Schilleriana*, as well as the other kinds, frequently produces flower-spikes in autumn, and may continue to do so throughout the winter; so that many, especially exhibitors, are inclined to pinch them, that they may yield them stronger and more abundantly in spring. This treatment, sometimes, answers

admirably for *P. amabilis*, *grandiflora*, *rosea*, &c., but for *P. Schilleriana* it is inadmissible, as the plants refuse to reproduce their flower-spikes until another year's growth is completed. F.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Asparagus racemosus.—This, which is one of the most beautiful of all the half-dozen ornamental species of *Asparagus* now in cultivation, is at present throwing up its feathery growths most vigorously at Kew. Its leaves are an inch in length, and about a line in width, and of the brightest green imaginable. If grown in quantity it would be most useful for bouquets, button-holes, and indoor decorations of all kinds; while the culture of the plant is easy in any ordinary greenhouse, or even in windows.—B.

Merendera caucasica.—This curious plant is now in flower with me in a pot in the greenhouse. The flower-buds rise from the centre of four or five green leaves, much like those of *Orchis fusca*. The petals, which are singularly narrow and long, are at first white, changing to lilac-rose, with a white stripe down the centre. It was sent to me under the name of *Colchicum Bisignani*. I have also *M. Bulbocodium*, *M. sobolifera*, and a single bulb of *M. Aitchisoni*, but have not at present succeeded in flowering any of them.—H. H. CREWE.

Chamædorea Martiana.—This is a dwarf and highly-ornamental species of Palm, well deserving of general cultivation for all kinds of indoor decoration. Its fronds are pinnate, gracefully arched, and not borne on a stem so high as most of its congeners. All the species are useful in plant-stoves when young, or in the tropical conservatory when they attain a considerable height, and they grow well in a compost of fibrous loam and sand. The pot should be well drained, and the plants must have a copious supply of tepid water at the root. If the pots are set in pans filled with water during the hot portion of the year, so much the better.—B.

THE PROPAGATOR.

MENZIESIAS.

THESE hardy and free-flowering little plants, commonly called Irish Heaths, may be increased by means of seeds, cuttings, layers, and division.

Seeds.

Raising *Menziesias* from seeds is a tedious undertaking, and therefore, seldom practised. Any one wishing to try the experiment, however, should get clean shallow pans, half fill them with broken crocks, over which place a layer of rough peat, and fill up with finely-sifted peat and silver-sand, three parts of the former to one of the latter. Sow the seeds, and merely dust a portion of the finest siftings over them, and over all lay a thin layer of damp *Sphagnum*. Place the pans in cold frames, and sprinkle the *Sphagnum* now and then by means of a very fine syringe, until the seeds begin to vegetate, when the *Sphagnum* may be removed. If they come up well, but not too thickly, leave them in the seed-pans undisturbed for a year, then prepare other pans precisely in the same way as for seed sowing, and into these prick off the seedlings about an inch-and-half apart each way. Here, too, they should remain for another year, at first kept in the frames, but afterwards quite exposed to the weather, being only sheltered from heavy rain, snow, and hard frost. After they are two years old, they may be transplanted into beds out of doors, thickly at first; but, on the next removal, to any place desirable. A peaty soil must be prepared for them in the beds into which they are first pricked out, but, afterwards, when they have gained some strength, the ordinary garden soil will be sufficient for them; if some peat, however, is mixed with it, they will appreciate the admixture.

Cuttings.

These afford the readiest means of increasing *Menziesias*, and they may be put in indoors or out-of-doors, and in spring or autumn. Out-of-door propagation by means of cuttings requires the assistance of a bell-glass or hand-light, and a shady and sheltered place, such as a border at the base of a wall, close wooden fence, or hedge. Excavate the soil where the cuttings are to be inserted to the depth of 3 inches, and replace it with peat as in the case of seedlings. In April or May, when the plants begin to grow, take some of the young shoots, make them into cuttings, and insert them under the hand-lights, which must be kept close and well shaded until the plants have struck root. Much dependence, however, should not be placed on these spring cuttings, reared out of doors, as many of them often fail, but those put in in autumn strike remarkably well, and just require the same preparation in soil as those inserted in spring. Autumn cuttings should consist of nice firm half-ripened wood of the current year, avoiding flowering points, and from an inch to an inch-and-a-half in length. Insert them firmly and thickly under hand-lights, which should be kept close, and covered over at night, if chilly, with a mat, using the same precaution against frost in winter. They may be inserted any time after the middle of July, provided they are obtained from plants grown in open and exposed situations. Next spring, if well rooted, they may be pricked out on a bed of peat, and some evergreen twigs stuck amongst them for temporary protection. Spring cuttings for indoor propagation may be obtained by using young growths from the out-door plants, or by having a few old plants in pots, and subjecting them to a little increased warmth, when they will start into growth, and yield quantities of soft young shoots, at least two months before those in the open border. These young growths, if used when about an inch in length, strike very readily. Prepare 6-in. pots for them by more than half filling them with crocks, then with half peat and sand, finishing off the surface with a layer of pure white sand. Insert the cuttings thickly, cover them with bell-glasses, place them in a gently-heated pit, and shade heavily. They may remain in these pots until they have become rooted and begun to grow, when they may be pricked off into pans, and, when too large for them, after full exposure in frames, they may be planted in the open border. Autumn cuttings consist of half or wholly-ripened

wood from out-door plants, and are generally rooted indoors for the sake of convenience or when it is too late for inserting them out-of-doors. From July to nearly the end of the year they may be struck in this way, which is just the same as that practised in the case of spring-cuttings, but shading is not quite so necessary, and the cuttings take a longer time to root than those do which are put in in spring.

Layers and Division.

Layers take two years to root well, after which they form good plants. Make a little incision lengthwise in the stem, near its middle, peg it into the earth, and cover it with some sandy peat. Division is the most natural of all modes of propagation, and the one most practised in gardens. It merely consists in lifting good many-branched plants and separating them with a sharp knife into as many pieces as have plenty of good roots attached to them, and planting each division separately. Old plants seldom flower so freely or grow so vigorously as strong young ones; therefore, breaking them up is attended with good results, both in increase of stock and improvement of quality.

W. FALCONER.

THE FRUIT GARDEN.

THE RASPBERRY.

ALLOW me to relate my experience as regards the hardiness of this fruit. In the gardens at Brodie Castle, in the far north of Scotland, we had a fine plantation of Raspberries trained to upright stakes, and also over arches. They were growing in good alluvial soil, but in a portion of the garden much shaded by trees. During the night of the 31st of January, 1866, the thermometer indicated 10° of frost, and for a week about that time the frost varied from 12° to 30° each night. Notwithstanding this, however, I can positively assert that not a single cane of the Raspberries suffered. At Dalvey, not far distant from Brodie, where the climate is generally good and genial, Raspberries occupy a portion of the kitchen garden that is so much shaded by trees as to be almost useless for any other crop, and the soil, though light, is damp, therefore the wood was never thoroughly well ripened. We always made it a point to have them pruned, staked, and tied before the winter set in, say in the end of October, and though some of the winters were so mild that we could scarcely get ice enough to fill our ice-house, still, some of them were very severe. One winter when I was there the frost came on in November, and lasted till March, varying in intensity from the freezing point to 30° below it. Even after thaw had set in, the frost lasted three weeks longer in the Raspberry ground than in any other portion of the garden. Notwithstanding all this, however, we never lost a cane through frost. Points of suckers and unpruned wood I have seen killed, but these are of no use, as they would have to be pruned back below the frost-nipped portions. In Lancashire, Cheshire, the hills of Derbyshire, Hampshire, Surrey, Middlesex, and other places, I have seen Raspberries grown under a variety of circumstances, but I never yet saw fruiting canes injured by frost. As regards the age of plants before they begin to fruit, I have always found them to bear freely the second year after planting. I never yet found autumn fruiting of the summer varieties to be detrimental to the next year's crop, but, as we have such excellent sorts for that purpose as the October Red and Yellow, there is no necessity for prolonging the bearing season of the summer kinds beyond August or the first week in September, and a few bushes pruned back in the previous May will yield sufficient fruit for the dessert. The quality of autumn Raspberries, although certainly not quite so good as that of July fruit, is, nevertheless, so good that they are eagerly sought after. As regards soil and situation, the Raspberry is one of the most accommodating of fruits; it will grow almost anywhere, and, indeed, I should always reserve for this crop, and some Monarch Gooseberries, positions in the garden, which, owing to their shaded character, would be almost useless for other crops, unless I required a few choice fruits for the dessert or for exhibition purposes, when I would treat them more kindly. Market-gardeners about London grow Raspberries without

stakes, but I have always found them to bear the finest fruits when supported, and I have always found the quality the same, whether spread out and tied to trellises, trained to upright stakes, or in arches.

F.

SELF-ADJUSTING LABELS.

In nearly all the descriptions which we see for labels to hang on fruit and other trees, a separate wire loop is recommended, to pass through a hole in the metallic label, for attaching it to the branch. This contrivance has the disadvantages of being complex, of wearing loose at the hole by swaying in the wind, and of cutting the limb to which it is attached, if not watched and loosened. A plan which we recommended and described some twenty years ago, we have found much simpler, cheaper, and, at the same time, self-adjusting. We have now some such labels which have been attached to side branches eight or ten years, without any attention, and which still retain their places without cutting into the bark. They are simply and wholly long strips of zinc or tin, narrow at one end and wider at the other—the narrow end being passed around the limb a little more than one turn; as the limb expands by growth, the elastic strip of metal yields to the growth. The name is written on the wider end. The metal may be either tin, and the letters

Label in use.

Showing a system of cutting without waste.

scratched in with a hard steel point; or zinc plate, written on with a pencil, according to the mode recommended by President Wilder.—*Cultivator*.

PROPER MODE OF POTTING VINES.

WE have to-day (February 13) passed through our hands a considerable number of fruiting pot-Vines that were struck from eyes last year. Before filling a span-roofed house 80 feet long with these, each plant was turned out of its pot and the drainage examined. The majority of these Vines were potted in very fibry but rather strong loam, packed very firmly into the pots. The drainage was ample and very carefully arranged: first a layer of larger crocks was put into the bottom of the pots, and it was finished off to the depth of 2½ inches with finely-broken crocks free from dust. All the plants thus potted and crocked were a perfect mass of fine healthy fibrous roots; so fresh and nice were they that one of our assistants remarked that the roots had begun to grow. The fact is that the roots are just now in the same fresh state as when they ceased growing last autumn. It was not necessary to turn them upside down to get the balls out of the pots; they are such a mass of fibrous roots that all that was necessary was to take hold of the Vine-stem and lift the whole out of the pot *en masse*. The remaining number were grown in a more sandy loam, and potted much less firmly. The drainage, by some oversight, consisted of just a piece of broken pot over the holes in the bottom of the pot. We tried to lift these out of their pots in the same way, but found that instead of a lift of ball and roots from the bottom of the pot, they were only liftable little more than half-way. The layer of soil at the bottom of the pots was soured and pasty-like, and with next to no roots in it. As a whole, there is not half the amount of roots in the same sized pot, and the young fibres there are not so healthy and sound. Here, then, we have the result of a violation of one point of culture making attention to other points of no avail. We have no hesitation in saying that the difference of these two sets of roots arose from the difference of drainage chiefly, and of potting partly, and, as a contingent consequence, the difference of watering. The want of sufficient drainage prevented the water from passing away sufficiently freely, and the loose potting held more in suspension than the pot full of firmly-packed soil did. And wherever these conditions exist, we have in all our practice found fewer rootlets or feeders, and these few of a different order from those in well-drained pot. In the case of Vines this is especially the case; the roots are few in number, dropsical-like, and never ripen or survive

the winter or period of rest in proper condition. Not only is this the case, but a pot firmly filled holds more soil, and, as a consequence, more nourishment. It also holds less water, for a pot with a given quantity of soil has room for less water than another with less and looser soil in it. Nor is this the only advantage; the very resistance offered to the root of a plant by a firm body of soil causes it to make more rootlets and of a better quality than takes place in a loose soil. It is a fact, too, that a soil holding less water in suspension induces a plant to multiply its feeders and take more complete possession of the feeding ground afforded it. A plant in the open ground will make more twiggy roots in a season of drought than in a wet one. The same holds good of plants in a pot. This is a point in plant culture generally that must be regarded as of great importance. Now for the deceptive part of the business in regard to Vines. A Vine in the circumstances as to potting and watering pointed out above as undesirable and injurious, may, and often does, make a stronger cane than another Vine under contrary and better conditions does. But I need not tell the expert that the cane or growth is of a different character. It is longer jointed, there is more pith in the wood, there are less compact and less symmetrical bunches formed in embryo in its buds; its roots do not come so rapidly into action as those of a fine fresh fibry character do. A word as to our mode of placing such Vines in their fruiting quarters. We have an objection to turning them entirely out of their pots into a border of soil, but think it desirable that the feeders should have more scope than is afforded in an 11 or 12-inch pot. We transfer the ball entire into Orchid-pots of the same size, with three tiers of large holes in them, and plunge them in the borders; the roots, of course, get out freely all round the balls into the fresh soil—and for midsummer fruiters this is a great advantage. Too much water at the roots is a great evil in the case of young growing Vines, but it is one that is scarcely possible with perfect drainage and thoroughly firm potting.—*The Gardener*.

Influence of the Stock on Pears.—One of the richest of Christmas Pears is Joséphine de Malines, and it is also one of the hardiest, ripening here—a very exposed situation in Norfolk, not far from the coast—on bushes in the open ground. It seems, however, to be a Pear peculiarly susceptible of influence from the stock on which it is worked. It is here on the Quince, grafted on the common Pear stock, on the Hawthorn, and on its own roots, a pendent bough, which touched the earth, having become layered and thrown out roots. In the first form (on the Quince) it bears early; but the fruit, luscious, is somewhat under-sized. The wasps attack it first of all. On the ordinary Pear stock at ten years old it has not fruited. On the Hawthorn the shoots are thinner than on either of the preceding; it has had fruit twice, but they did not become soft; so far it is not a success. On its own roots it has fruited three times (same age as others) and the fruit is very unlike that of the parents from which the bough rooted. The fruit is somewhat larger, less covered with russet, greener in hue, more vinous, and less honey-sweet. It is also later in ripening. This day (March 2) I have been examining the trees; on the ordinary Pear stock, if there be blossom buds, they are so backward that they cannot be easily discerned; on the Hawthorn, ditto; on the Quince the knots of bloom are very perceptible—as forward as Doyenne d'Été, the earliest Pear on its own roots; but the blossoms are almost ready to expand—the forwardest in a collection of about thirty kinds—very abundant too, which is the first time they have been so. In the previous nine years of its separate existence, the blossoms have been sparse, but have set fairly. Our trial goes to show Joséphine de Malines is best left to itself—i.e., on its own roots—but is a good Pear on the Quince.—G. G.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Keeping Grapes.—A correspondent of the *Rural Press* keeps Grapes fresh and in good condition till April, as follows:—Gather carefully, handle little, break none, and then pack very carefully in alternate layers, with clean dry Wheat chaff, not over three layers to a box; close the lid and keep the box in a dry apartment, where the Grapes may be as cool as practicable without freezing. The dry chaff absorbs all moisture, and imparts no bad flavour.

Fruit Crops and the late Frosts.—On the morning of the 11th inst. 15° of frost were registered here, and all the early blossoms of Apricots, Peaches, and Nectarines, were cut off where not well protected. I am afraid the earliest Pear blossoms, although not expanded, will have likewise suffered, especially on south aspects. The show of blossom buds this year on Pears, Apples, Plums, and Cherries, is very great, owing to the partial crops during the last two years, and the fine summer of last year having ripened the wood well.—WILLIAM TILLERY, Welbeck, Notts.

The seasons alter: hoary-headed frosts
Fall in the fresh lap of the crimson Rose.—Shakespeare.

We have had a rough week of it here. The thermometer on Tuesday and Wednesday mornings (10th and 11th) indicated respectively 14° and 15° of frost. Some damage has, I fear, been done to Peaches and Apricots on the walls, in spite of protection; but the blossoms this season were so numerous, and looked so strong, that I hope we shall save a crop.—E. HOBDAK, Ramsey Abbey, Hants.

A HOLIDAY TOUR.

By THE EDITOR.

PARIS, March 12.—Devoted to his institutions, the Briton is very hard on his climate. If anything remarkable in the way of vegetable produce comes out of other lands, the merit is not sought in the system or the cultivator, while all our own shortcomings are accounted for by the climate, so that even those who heap most abuse upon it should be grateful to it for settling so many questions. But if here, on this 12th day of March, with a heavy fall of snow under foot, and a most bitter north-east wind raking the street, some would probably begin to suspect that there was, at least, one other climate in the world as little like that of Paradise as is our own. In such weather, however, the southward-bound traveller may go farther and fare even worse than in this famous city. The spring flowers in the public gardens only peep here and there through their white blanket; yet there is even now something to interest the lover of gardens. Let us, then, in passing, enjoy it for a day. The Garden of Plants is, perhaps, the ugliest in the world as a botanic-garden; the Grand Trianon, at Versailles, being quite its equal for ugliness, as a palatial one. But it has some interest, in spite of its management and design, both of which are bad, and will repay us for visiting the houses on this wintry day. The house represented on the opposite page is one devoted to plants that endure ordinary greenhouse temperature, and it contains a few specimens of a type which we most require for use in our large cool-houses, not that all of these are in any sense peculiar to it, as, of late, the cool conservatories of our large plant-growing nurserymen contain numbers of fine species suited for the purpose. First, to arrest attention by its grace is a Bamboo, not the large tender Bamboo which requires heat, but one of those hardy sorts (*Bambusa viridi-glaucescens*) which come from cool regions in India and China. In a cool-house, planted in a bed or border, and not in a pot or tub of any kind, and with not less than 12 feet of head-room, these are indeed beautiful plants. In a niche, in the back wall of the house, there is a bust of Victor Jacquemont, the young naturalist, who perished in India, when there as a collector for the Garden of Plants, and author of those charming letters reviewed so favourably in the "Edinburgh" some time ago. Immediately in front of the niche, springs up a plant of the slender hardy Bamboo (*B. gracilis*), the shoots of which rush up by the fine bust, gracing it with long fairy wands, clustered over with leaves that toss from their branches as gracefully as the falling spray from a mountain rock. There are no plants more worthy the attention of those who have to plant and arrange conservatories than these Bamboos. Another family, the Chamædoreas, also, possess extraordinary merit for the same purpose. A specimen of *C. elatior*, here planted out in a bed, at the first glance reminds one of a Bamboo, in consequence of having sent up many stems; seen thus, this handsome Palm looks much more graceful than when grown to a single stem in a pot or tub. The fine effect is owing to the fact that the foliage is so compact, that no confusion is produced by a number of stems. It is probable that all the Mexican Chamædoreas will prove equally valuable for planting out in conservatories. Other plants here, suited for the planting of like structures, are *Cocos australis*, *Jubæa spectabilis*, *Rhapis Sirotsik*, *Livistona australis*, *Chamærops Martiana*, *C. Hystrix*, *C. Griffithiana*, and *C. Palmetto*, several kinds of *Phoenix*, and *Areca sapida*, not to name others more frequently employed. This house suffered much during the bombardment of Paris, the whole end, nearly 40 feet high, being smashed in, one wintry day, by a shell. It was a sad time for those in charge; starving themselves, they had the additional misery of seeing their favourite plants perish from cold; and, as soon as the holes and rents made by the German shells were patched up in the spring of 1871, came the Commune and its bullets, several of which are now imbedded in a fine *Beaucarnea*. Later still, fourteen of the defenders of the Commune were ranged against the terrace-wall on which the house is built and shot dead. Under circumstances like these who could expect good cultivation? So the plants look about as poorly as possible, but the real cause of this, and of the disgraceful state of the gardens generally, is not the Commune, nor the war, nor any number of wars—but, because the chief of the

horticultural department is simply a botanist, and, in no sense, a cultivator; he is "professor of culture" without any knowledge of culture. There are excellent horticulturists employed in the garden, whose efforts, however, are paralysed. The result of all this is, the ugliest garden and some of the worst-grown plants in Europe. The management of this place has such an important bearing on the proper management of public gardens generally, that we shall, probably, again take an opportunity of alluding to it.

The Paris Fruit and Vegetable Market in March.

With its merry clatter of ten thousand tongues, and the many striking faces of the market-women, the Central Market of Paris offers, particularly in the early morning, a never-failing source of interest, even to those who confine themselves to the study of the human species. But we, who love Violets and those precious little fresh Rose-buds, that look as if born in May and gathered before they were kissed by the noonday sun, and on whom, perhaps, the brightness of some of the eyes and faces set in these snowy caps is not, in consequence, wholly lost, may be permitted another stroll along the well-known stalls. Many who see this market in perfection in summer and autumn do not know it in early spring. The bitter cold of the early March morning has no noticeable effect in reducing the numbers who usually throng the market, though it certainly must mar their comfort. The large extent of the Great Hall, however, saves them from such drenchings as the people suffer in Covent Garden on a wet morning. The piles of Mushrooms are, perhaps, the most striking things in the market. These are not in punnets, as in Covent Garden, but thrown out on wide benches, and heaped up as London hawkers heap up their barrows with Oranges when plentiful. As to quality, these Mushrooms are excellent indeed; nearly round, on an average about the size of a Horse Chestnut, perfectly white, fresh and delicate in texture and flavour, they look as if each was selected by a good judge from the myriads that are often seen on a hill pasture on an autumnal morning. These Mushrooms all come from the profound depths and darkness of the old stone mines beneath Paris and its environs. Almost equally round, and chubby, and tender, are the little Carrots, so plump and small, indeed, that they are not bunched, but tumbled into barrels like Nuts. Piles of large Pumpkins strew the ground; these have been kept through the winter, and form, when green vegetables are scarce, an important article of food. In the United States, long-keeping Gourds are quite as important a crop as the Turnip with us, if not more so. It would, therefore, seem desirable that their value should be better known in England, where they are as easily grown as the Vegetable Marrow, the only Gourd really popular with us. As compared with the large Gourd of the Paris market and the best Squashes of the Americans, it is of little importance as a food supply. The common garden Turnips are seen here, but are not so abundant as the Navet, which many think better, and which is pretty regularly supplied to Covent Garden from the Paris gardeners. But there is another very curious Turnip here—the Navet de Meaux. This is a singular-looking kind, usually more than a foot long, frequently curled in form, and only as thick as a Cucumber. These are sent to market in a peculiar manner. The top is cut clean off, a hole pierced an inch below the cut, through which a few straws are passed, which permit of a dozen roots or so being united in a bundle together. These Turnips remind one of the huge white Radishes that one sees in the Chinese quarter of San Francisco, but are not nearly so well-grown as the snowy and tender roots of the careful Chinese gardeners. Passing by many vegetables common to London and Paris markets, we observe that the Shallot offered everywhere here is the true kind, a distinct species with a slender bulb and a grey coat, whereas the Shallot now commonly sold in Covent Garden, and evidently a small variety of the common Onion, is a roundish bulb, with a shining dark brown coat. Some not very important vegetables, almost out of date with us, are here yet seen in abundance, such, for example, as the Rampion, with its long and slender creamy-white roots, which are grown to perfection in the light rich soil of the market-gardens. Quantities of Green Peas, from the south, and piles of Globe

COOL CONSERVATORY IN THE GARDEN OF PLANTS, PARIS.

Artichokes, do not interest us much, because they are obviously products of a fairer clime; but the great feature of the market is the quantity of excellent saladings of every kind, from the long and graceful tufts of Chicory (blanched in caves), to the fresh green rosettes of the tender Lettuce, which Paris is never without. Those sent from Paris to the London market, however good in quality, are never seen there to such advantage as here; their spotless verdure is tarnished by packing and the journey. Though the whole process of growing these saladings is carried on within the very walls of Paris, there are many who suppose them to be (like the Green Peas and the Artichokes from Africa) the produce of a warmer climate. Let us see how they are grown, and glance at

The Paris Market-gardens in Early Spring.

The market-gardens immediately round Paris are now, for the most part, covered with glass—large clear bell-glasses, about 18 inches high, and small shallow frames. The gardens are very small; seldom more than an acre, often less, and usually an oblong piece of ground, enclosed by white walls, with a house, sheds, &c., in one corner. There is no space for walks; the ground is too precious and too dear. Small paths between the crops suffice; the place is rarely seen by anybody except those who cultivate it. The large bell-glasses first strike the eye, from the healthy and beautifully green verdure with which each is filled. A huge Cos Lettuce rises to near the top of the glass; while, at its feet—pigmies round a giant—there is a ring of those dwarf tender Cabbage Lettuces so much seen in Covent Garden in winter and early spring. The icy breath of the north is blowing over the garden, as over all France and England to-day; but the plants are cut off from it, and sitting in the sun within. We have all laughed at Smith's bottled sunbeams; but bottled sunbeams are, fortunately for lovers of tender green-meat, among the actualities. Sometimes these glasses are thickly placed on shallow hot-beds, when used for winter and early spring crops; sometimes on slightly-sloping beds of rich light soil. In frosty weather they are covered with straw mats, which are taken off during the day-time. The bell-glasses are used, for the most part, for the production of Cos Lettuces; the shallow frames for the Noire Lettuce, so much in demand in winter. Among these Lettuces are, in some cases, already planted and thriving, the Cauliflowers that will replace them by and bye, and come in for use early in the season. Whole frames are occupied with seedling Melons and with seedling Tomatoes, with which the rich ground will be cropped before this day two months, and which will yield an abundant return. Radishes and many other saladings are gathered from these frames in like manner, and, in this way, the market is rendered almost independent of the season or the weather. The opinion prevails widely that the smaller the holding the worse the culture. It may be so in some cases; very small holdings and very high culture are the rule here. The owners are certainly as hard-working and, apparently, as poor men as any independent workers can well be, but they appear to gain, at least, as good a livelihood as the farmers who try to cultivate a hundred or more acres in the best parts of Canada. This Paris market-gardening is, however, so essentially peculiar and special that it would be unsafe to deduce any broad conclusions from it alone. The culture in the open fields round Paris is much inferior, and very scratchy and imperfect. Hence, the Parsnips and various other vegetables raised in that way seem very inferior to those seen in the London market. In and near Paris one rarely sees much variety in one garden; the tendency is to special culture. Thus, one whole town and its environs is devoted to Asparagus, another district to Navet and Turnip culture. Mushrooms form a speciality, and even the forcing of Asparagus is sometimes made the main effort of a life. One may look in vain in any of these gardens for either Rhubarb or Seakale. It is odd to reflect how slowly and curiously ideas sometimes travel. Go into the deserts of Utah and enter the garden of a Mormon elder; or, farther still, six or seven thousand miles away on the coast range of the Pacific, and visit a Californian fond of his garden, and you will find Pie plant (Rhubarb) and Seakale as well known as the Potato. Cross the Channel, and in two hours we are in a land where they are seen no more, except, perhaps, in very rare cases as curiosities, or in a public garden in their places in the botanical arrangement.

COTTAGE GARDENING.

By J. MAIN.

It is universally admitted that a piece of garden-ground attached to a labourer's cottage is the greatest boon that can be afforded him, more especially if he has a young family to support. This object has always been recommended by the societies instituted for devising means for bettering the condition of the labouring poor of this kingdom; and on the recommendation of these societies the present allotment system was founded. The produce of even a very limited spot of garden-ground, if well managed, not only adds greatly to the domestic comfort of a working man, but is actually the means of improving his moral character, by giving him employment in his hours of leisure, and an amusing and profitable occupation on a spot which he can truly, and with pride, call his own. But the occupation of a piece of ground is not sufficient unless accompanied with plain directions for the guidance of the labourer in his management thereof; for, although a majority of our rural population are pretty good gardeners in their own homely way, many there are who need advice, and almost all are ignorant of the most economical methods of culture. This information is so plainly detailed that the directions can hardly be misunderstood. When a labourer is so fortunate as to have a garden attached to his cottage—or if he be equally fortunate in having an allotment in some neighbouring field—his first care should be to ascertain whether his piece requires draining, and next, to be sure that it is properly and securely fenced, if fencing be at all necessary.

Draining and Fencing.

Land is frequently liable to be too wet for the successful cultivation of kitchen vegetables, from various causes. It may be too damp from its being situated on the lowest dip of the surrounding surface, to which rain or melted snow naturally flows; or the soil may be constantly too moist from its disposition to retain water like a sponge, such as is met with in bogs. It may be in the same drenched state from having a thick bed of clay beneath the staple, or from having land-springs oozing out of a bed of gravel above it. Now, from whatever cause land becomes too moist for the purposes of the cultivator, its improvement can only be accomplished by thorough draining; and, unless this be effectually done, the crops will not only be deficient or inferior, but the manure bestowed will be quickly consumed, and washed, as it were, out of the soil. Although a cottager should be apprised of the necessity and effects of drainage, it is but seldom that he need be at much trouble in laying his ground dry; for, even in the worst cases, a ditch round the outside will generally be sufficient, taking care to make at the lowest corner some kind of outlet, either into a common and lower ditch, or sinking a swallow through the holding soil, from which the water may soak away into some lower and more porous layer of the ground. Few cottagers need very much advice as to fences. Simple boundary lines are often all that is necessary. In allotment pieces, a footpath all round is a sufficient mark, and better than any kind of hedge, which is usually a harbour for slugs and hurtful insects. But if the cottage-garden abuts upon a waste or common field, then a good fence is necessary. This should either be a ditch and hedge, or a deep ditch and paling—the former is the most common and most lasting.

Trenching and Manuring.

When a labourer enters upon the tenancy of a piece of ground, whether it be an old enclosure or a new allotment, he should, in the first place, resolve to trench the whole plot, unless it has been very recently done to his hand. This, however, he need not think of doing all at once, because he will find it more convenient for him to do it piecemeal; for, at whatever time he may get possession, it behoves him to see what may be done on the instant in the way of getting some kind of crop on part of the ground, and for which simple digging may suffice. The trenching, however, should always be kept in mind, and executed as opportunity allows, and immediately cropped. Trenching is useful to the most shallow rooting plants; and for deep-rooting kinds it is indispensable. It deepens the staple, and renders all subsequent operations more easily performed; it buries weeds and a weedy surface, turning what is useless into the food of succeeding crops. Trenching not only allows a greater range for roots, and permits the sinking away of heavy rain from the surface, but in dry weather allows the ascent of moisture from below to keep the loose surface more moist. The depth to which trenching may be done depends on the natural depth of the staple, and on the nature of the sub-soil, or underlayer. If the latter be pure gravel or strong clay, too much of these must not be brought to the surface at once, unless the clay be of that kind which falls to powder by the action of the weather. If the sub-soil as well as the surface be loam, there is no fear of trenching too deep, even as far as 2 feet; and, in respect of a clay or a gravelly under-soil, though not brought to the surface,

the bottom of each trench should be deeply broken up with the mattock, in order to move and deepen the staple. Whatever the nature and character of the staple may be, it is certain that all and every description may be improved. Manuring as frequently as possible assists and betters every kind of land. Clay is improved by any lighter kind of earth or decayed litter, or sand, ashes, and the like; because these break the tenacity or toughness of the clay, and render it easier to cultivate, and allow the roots of plants greater scope, besides admitting a freer passage to both air and rain-water. A light sandy soil is improved by the heaviest kind of manure, or by dressings of clay or loam, because manure laid upon sand sinks into the ground, and, being quickly absorbed, of course requires more frequent application. Loam of any kind or colour is the best for gardening purposes; it only requires to be well laboured by occasional trenching, dug at least once in the season, and hoed frequently to keep the surface loose. But as it is, like other kinds of soil, liable to be exhausted by cropping, it must be kept in heart by occasional dressings of manure. Obtaining sufficient supplies of manure is one of the greatest difficulties which the cottager has to encounter, especially if he keep neither cow nor pig; and unless he lives by the side of a free common it is not in his power, nor is it worth his while to trouble himself with either, except under circumstances hereafter alluded to. But an industrious man may collect as many matters of one kind or other as may be sufficient to dress one-third, or at least one-fourth, of his ground once-a-year. For this special purpose he should have a hollow pit or place between his house and garden, into which every kind of drainage from the former and refuse from the latter should be thrown. To this may be added all sorts of litter and cattle-droppings from the lanes, roads, or commons, together with ashes, lime rubbish, marl, or chalk—all which, when thrown together and turned once or twice till sufficiently rotten, will be found excellent manure. As the success of a cottager's garden depends solely on his ability to keep his ground in heart, every exertion must be made to secure this advantage; and if, at any time, he happens to have more of any kind of crop than he wants for the immediate use of himself and family, this he should exchange for some kind of dressing; or, if he sells it, the sum should be laid out in the purchase of good manure for his garden, for, by such exchange or purchase, he will be sure to reap a double advantage. Another thing which the cottager who is short of dressing should be aware of is, that manure in a liquid state is most effective. When single plants, as Cabbage, or a bed of seedlings of the same, or of any other kind, require watering, manured water—that is, such as had some kind of dung steeped in it—should be used. The drainage from dung-hills is most valuable for such purpose, if not too strong; but its strength is easily reduced by the addition of a portion of clear water. In some countries, where the soil is dry sand, the cultivators have cess-pools sunk on purpose for making this liquid-dressing, which answers the intention admirably. By the knowledge and application of such means, fine crops of kitchen vegetables may be produced, while, if they are neglected, a very different result will be the consequence.

Rotation of Crops.

Another means of keeping ground in good heart is by following a judicious rotation of cropping. It is bad management to grow the same kind of crops repeatedly on the same spot, and, therefore, the crops must be made to change places every year. This will be practically explained hereafter. The proportion of crops to the whole garden and to each other is a material affair for the consideration of the cottager. That crop which remains longest in use, and which, consequently, is most serviceable in a family, will, of course, command the greatest share of the ground. In all cases, Potatoes will have, undoubtedly, the preference, not only because they are a good substitute for bread, but because a safely-secured winter-store of them is of the greatest importance to the labourer. Supposing, then, that the principal part of the ground is occupied with Potatoes, the remainder will receive those that are the next valuable as eatables, namely, Cabbages and their varieties, Carrots, Parsnips, Onions, Turnips, common Beans, and, above most of the latter, the useful rough Runner Kidney Bean, so extremely useful in a cottager's family. There are some other vegetables which may be recommended for a labourer's garden, but they will be noticed hereafter. There is one circumstance which every manager of a garden, especially those who are confined to a limited spot of ground, should ever be well aware of—and that is, the practicability of having a constantly recurring succession of crops on the same piece of ground. This is a practice which farm or rural labourers in general are but little acquainted with, though, when judiciously planned and executed, it is of the greatest advantage. Mixed crops are allowable in cottage gardening—for instance, a sprinkling of Radish and Cos Lettuce seeds may be sown with the Onions, and when the Radish and Lettuce are drawn, being ready for use, the

Onions suffer no injury. Broad Beans are sometimes planted at the same time and in the same drill with Potatoes, and without any very visible damage to the latter crop. But, in order to keep the ground in full employment, all the crops, that is, the standing crops, must be sowed or planted in drills or rows, with the intention that, before the first crop is off, another shall be put into the intermediate spaces to follow in succession. This is quite practicable with all the Cabbage tribe, or with any other kind of vegetable which may be used in any stage of their growth. Of this description are the Cabbage, Savoy, Onion, Lettuce, &c.; and when such are planted alternately with others, which must stand to acquire full perfection, the first may be used out of the way as soon as they press injuriously upon the second. In this way many more useful vegetables may be raised on a given portion of land than by the old-fashioned custom of sowing broadcast, only one patch of each of the common sorts occupying the ground for the whole summer. Even the Onion-ground may be planted with Cabbages just before the former are fit to pull, which plants, whether Savoys or common Cabbage, become fine useful stuff before Christmas. This constant routine of cropping and re-cropping may be considered as out of the power of a day-labourer to perform; but, whether he may have time or not, it is highly proper that he should be made acquainted with every practical matter which he may endeavour to turn to his advantage.

First Year's Arrangement of Crops.

The management of a cottager's garden must commence when he takes possession. As Michaelmas is the usual term at which cottagers shift their quarters, and, moreover, the most suitable period at which to begin any system of gardening, we shall therefore commence our series of instructions from this said quarter-day, and proceed onwards with the season. The very first thing requiring attention, as already mentioned, is to see that the fence, if one be necessary, is in sufficient order; and the next, to get ready a hollow near the house to receive all the drainage, slops, ashes, and offal therefrom, together with any rank herbage or weeds which may be cleared off the surface. Then, beginning at the bottom of the upper half of the garden, let a good large piece be dug on which to plant two or three hundred early York or Battersea Cabbage in rows one foot apart. The plants should be examined to see if there be any knots or clubbing on the root or bottom of the stem, in which case the affected plants should be rejected. Dib in the plants as deep as the lower leaves, and fix them tightly in the soil—now the labourer need not be afraid of planting too many in this order, because every alternate row must be used as soon as wanted, so that the intermediate space may be dug or not, and planted with long-podded Beans about the end of January. The rows which are left for the principal crop of Spring Cabbage will be in use during May and June, and they should be gathered by rows in succession. When the first row is used, begin the second, clearing off completely as the Cabbages are wanted. The advantage of this mode of taking the crop is, that it allows the cleared ground to be dug and re-cropped if requisite. From the time the Cabbages are planted until the Beans are put in, the ground should be frequently hoed between when the surface is moderately dry, but not at all if wet. When the Cabbages are planted, there is nothing more to be done in planting or sowing till the spring—but, before that season, the cottager must be getting the rest of his ground ready for the spring crops. As much of it as possible should be trenched; and, if he can manage to trench the whole, it would be a good job out of hand. Every labourer knows how trenching is done, and, therefore, advice on this point is needless; it may just be observed, however, that the trenches may be made $2\frac{1}{2}$ or 3 feet wide, and as deep as the staple allows—the first is wheeled to the other end to fill the last trench. The top-spit or spadeful of the second is turned to the bottom of the first, and the remainder is raised to form the new surface, this being repeated over the whole piece. In the autumn or winter-fallowing of garden-ground the surface is either laid flat or in ridges. If the soil be light and sandy, it can hardly be laid too level, because such soil requires no amelioration by frost, nor any exposure to the sun and drying winds to exhale away its moist riches. But if the soil be naturally heavy and clayey, then the surface should certainly be laid in ridges, not only that it may be mellowed by frost, but that it may be rendered as dry as possible before seed-time. These last observations are applicable to digging as well as trenching, for strong land should always be laid in ridges during winter. There is another advantage of ridging land to a cottager who may have an opportunity of getting it into this state during the autumn; it is, that in the spring, when so much business is going on in the fields, any portion of the cottage-garden is much more readily got in order for either seeds or plants than if it had to be dug at that busy time, when every hour of the labourer's time is so valuable to his master and himself. During the winter the cottager must also set his head to work about proportioning his

ground to the quantities of vegetables which he may wish to cultivate for himself and family. This he ought to arrange for himself, because, without knowing the size of the garden, a writer can hardly give advice that would be useful on this part of the subject; but, that he may not be left without some kind of guide in this affair, we shall presume that he has half-a-rood or twenty poles of garden, which is not more than is really necessary for a married couple having three or four children. Calculating, then, upon this quantity of ground, we shall set down what we think should be the proportions of the crops respectively, and which will serve as a scale to direct every cottager who may have either more or less of the supposed quantity of twenty poles. We may next suppose that the piece of ground is in the shape of a long square, 38 yards long and 16 yards wide or over. This area will contain about 20 poles; of this, 19 yards in length must be marked off at one end for Potatoes, and which should be either trenched or dug in autumn or winter, to be ready for planting in the ensuing spring. This division will therefore lie fallow till April. Next to this, mark off 7 yards in length for Cabbage, which should be dug and planted, as already directed, as soon after Michaelmas as possible. About the middle of January, let us suppose that the second, fourth, sixth, and eighth rows of the young Cabbage have been used, point over with the spade the spaces where they stood, and immediately thereon dib in by line six rows of long-pod Beans at 4 inches apart, and cover in. If the ground be loose and puffy, tread it well before the Beans are dibbed in, as they strike root best in firm soil. Thus there are 19 yards left for Potatoes, and 7 in length occupied by Cabbage, leaving 12 yards to be cropped in March and April. This reserved portion may be divided into four parallel beds of nearly 3 yards each:—the first Parsnips, then Carrots, next Onions, and last a bed which may be a seed-bed of Cabbage sown with Radish, Lettuce, and early Dutch Turnip. A narrow slip of this last or uppermost bed may be parted off for potherbs, flowers, &c. We have now set forth how the garden may be cropped in the first year, and mentioned what we consider the most profitable kinds; but it is necessary to revert to the manner of sowing and management during their growth, and here we may repeat that all will be the better for a sprinkling of manure, but, as it is not likely that this will abound, whatever can be got together must be reserved for the Potatoes. The other crops about to be particularly noticed, may be assisted in their early growth by manured water as already alluded to.

The Parsnip.

This very nutritious root is luckily easily cultivated, and when sown in drills on deeply dug or trenched ground, yields a bulky return, which, when stored in dry earth or sand, remains long useful. The drills may be 14 inches apart, the seed sown thinly on shallow furrows opened by line with the corner of a Turnip-hoe and lightly covered with the same. When the seedlings have risen 2 inches high, they should be thinned to 5-inch distances, and the ground always kept well hoed between the rows to kill weeds and benefit the plants. The seed is very light and cheap, 1 ounce being as much as a cottager will require. There are two sorts; the common long one suitable for deep soils, and the short hollow-crowned sort, which is of superior quality, and best fitted for shallow soils. Parsnips may be sown either in March or April, and they will be fit to take up in October. When dry and freed from earth and remains of the leaves, they may be stored among dry earth in any corner of a shed, or other place safe from air and damp.

The Carrot.

This well-known and extremely useful vegetable is, in every respect, except in qualities, very much like the Parsnip, requiring the same treatment as to sowing in drills, thinning, hoeing among during the summer, and taking up and storing in October or November. In thinning the seedlings, they should be left 2 inches apart, and when they have gained a useful size, every other one may be drawn for the pot, leaving the main crop at 4 or 5 inches asunder. There are several sorts of Carrots, but the Short-horn and the Altringham are the best for the cottager. A clayey soil is unsuitable for Carrots; but we have known ingenious labourers, whose gardens were a stiff clay, grow very fine Carrots notwithstanding. Their method was this: the ground was prepared by deep digging, and, at seed-time, ranks of deep holes were made by line along the bed with a crutch-headed taper-pointed dibber; the holes were filled with rich, mellow compost, and on the surface of each two or three single seeds were dropped and slightly covered with a little more of the compost. When the seedlings appear, one only (the strongest) is left, which grows rapidly, and gains a perfect natural form and good size. The ground intended for Carrots had better be sown at twice, one half in March and the other half in April, because it is found that if the worm (a pest we know not how to banish) attacks the crop, the

earliest sown suffer most. Carrots may be sown at other times than in spring, but these sowings are never a profitable crop. The seed requires to be well rubbed between the hands over a cloth before it is sown, otherwise it cannot be distributed equally, the seeds being apt to cling together if not well rubbed.

The Onion.

This is one of the most useful of all cultivated garden vegetables to a cottager; it gives an agreeable relish to almost everything else, and therefore requires the especial attention of the labourer. The ground should be well prepared by manuring (if possible) and careful digging. Sow in drills, 10 inches asunder, about the middle of March, rather thickly, because, as they are useful as soon as they are of the size of a crowquill, the drills may be thinned regularly as they are wanted either to use or sell, taking care that all the strongest are left 4 inches apart to come to perfection. The bottom of the shallow furrow made to receive the seed should be firmly trodden with the foot before sowing, and slightly covered with the rake. The intervals must be kept free from weeds by the hoe, and the drills by the hand throughout the growing season; and, in August, sooner or later, the Onions will be ready to pull. When pulled, they should be laid together upon a bare part of the ground for a week or ten days to harden. After this, the greater part of them should be roped, as the most convenient way for a cottager to keep them, or otherwise kept in a dry loft. There are many different sorts of Onions, but the Spanish and Deptford are two of the best for the cottager's purpose. Onions are also sown in the autumn to draw young for spring use; but this will be again mentioned at the proper time.

Radish, Lettuce, Turnips, Peas, and Herbs.

On the remaining bed, to be cropped in March (it being about three yards lengthwise and the whole breadth of the garden) room may be found for a small seed-bed of Cabbage and Savoy mixed, another for white Silesia Cos Lettuce, another for Short-top Radish, and the remainder for early Dutch Turnip. All these are sown broadcast, but regularly, over the fresh-dug surface and raked in. The Turnip-seed should be sown last, as early sowings soon run to flower. If it be advantageous to the cottager to raise a crop of early Radishes for sale, he may take a bed off the Potato ground; sow at Christmas, or soon after, pretty thickly on the fresh-stirred bed, rake the seed well in, and smooth the surface with the back of a spade, and cover the whole bed with dry Fern or short littering straw 6 inches thick. The covering is kept on till the seedlings are above ground, and then the covering is drawn off every mild day, but always kept over at night till all fear of frost is past. The labour and care of raising early Radishes is of little use to a cottager unless he is sure of having a ready sale for them. We have, as yet, said nothing of Peas, because we do not think they are profitable to the cottager; but, if he resolves to have a few, one row only of Knight's Marrow will be enough. They may be sown any time in February below the Cabbage across the garden, and, if sown thinly, earthed up once, and staked when 5 inches high, are very productive, but, as already said, not profitable. When the beds of Parsnips, Carrots, and Onions are sown, the alleys between should be immediately planted with Cabbage, if plants can be had, for every foot of the ground should be cropped. At this time (March) the narrow slip at the upper end of the garden may be furnished with a few herbs for seasoning soup or broth; namely, a plant or two of Thyme, Mint, Sage, Savory, and Marjoram, with a drill of Parsley sown as an edging. Above all, half-a-dozen or more roots of Rhubarb for the leaf-stalks, which will be found most useful in the family. Seedling plants or odd roots may be had of any market-gardener.

Potatoes.

Preparations must now be made to get in, next month (April), this, the cottager's principal crop. Much of his domestic comfort during winter will depend on his having from ten to fifteen bushels of good sound Potatoes pitted near or well-covered up in some safe corner within his house. We have allowed one-half of his ground for this crop; and if the sets be properly planted, and the crop properly cultivated during the summer, we calculate that the yield will be at the very least fifteen bushels, besides those used in summer. This is a fine store for a labourer to look forward to, saying nothing of his store of Parsnips, Carrots, and Onions, all most useful additions; but he may rest assured that unless they are used with economy, twice the quantities would be of little use to him. We have been much among labourers who had gardens; but with all the authority of a master, and with all the best advice of a friend, we never could prevail with many of them to make the best use of the advantages they possessed. To begin on the Potatoes as soon as they were of the size of Walnuts, thus devouring bushels at a meal, was a common

piece of extravagance! Selling the whole crop for one-fourth of the value, to save the trouble of taking up and storing, was a frequent occurrence; and great waste in the cooking was, in many cases, too visible. But, on the other hand, some, who husbanded their resources lived comfortably, and showed the manifold advantages they and their families derived from possessing a small piece of garden. The ground reserved for Potatoes will hold ten rows at 2 feet apart, and will require about $1\frac{1}{2}$ bushels cut into sets to plant the same, placing the sets about 8 inches asunder in the drill, covering full 8 inches deep. The sets should be as large as the size of the Potatoes will allow, each having at least one eye, rejecting, or not counting on that at the bottom, as no shoots spring from it. The best way of cutting the sets is first to split the Potato down the middle; each half may be divided into two or three sets, according to the number of good eyes, taking as much of the substance of the Potato with each eye as possible. Some curious growers make sets of the crowns, which they keep and plant by themselves, for the purpose of being first used, as the tubers from these sets always come earlier than those of the other sets; but this is a refinement in the culture with which a cottager need not trouble himself. There are a great many varieties of the Potato; some are very early ready for use, such is the Frame; others finely-flavoured and handsome in shape, as the Lapstone Kidney. These, however, from their scanty yield, are unfit for the provident cottager. The best for his purpose, as uniting quality with quantity, are the Champion and the Early Shaw; these are best for immediate use as soon as their tops decay; but for long keeping and storing, the Devonshire Apple and Yorkshire Red should certainly be preferred. Two-thirds of the whole piece should be planted with Reds, and the other third with the Shaws and Champions; and, as soon as the tops of these last decay, they should be taken up and the ground immediately re-planted with Cabbages; Savoys, or other Winter Greens. When the tops have raised 5 or 6 inches high, they should be earthed up for good, for once earthing up is enough; but the vacant spaces between the rows should always be kept well-broken up and loose, by a heavy hoe, fork, or mattock, taking care not to go too near the roots to disturb the runners. When the flowers appear, let them be picked off; for this adds as well to the size as to the number of the tubers. In choosing the kind or kinds for planting, procure, if possible, those which have been named above, and which have been grown on a different kind of soil and in some distant place; for no kind of Potato succeeds long together in the same garden or district. Much has been said and written as to whether Potatoes should be planted whole or cut into sets; but it is now settled that a bushel cut into sets yields a much greater return than if they were planted whole. The yield, however, depends greatly on the quantity of manure bestowed; if dressed as thickly as a farmer dungs for Wheat or Turnips, it may be dug in before planting; but if manure is scarce, the next best plan is strewing it along the bottom of open trenches, in which the sets are placed and covered with loose earth. Where there is no shed or outhouse for storing Potatoes from the air and frost, pitting them in the garden is the most convenient way. A narrow pit about 10 inches deep should be made on a dry spot, in this a bed of dry Fern or straw is first put, then the Potatoes are laid in a ridge of the required length, and covered with a good coat of straw. Over this, earth dug from the sides and ends is piled over a foot thick, forming it like a ridge, and patted smooth with the spade to throw off rain; a trench being left open all round prevents all surface-flow from soaking in. Parsnips, Carrots, &c., may be pitted in the same way.

Scarlet Runners and other Beans.

When the garden is all cropped, as above directed, the next object demanding attention is thinning the rising crops, and keeping the whole free from weeds by the hoe and hand. About the 1st of May, a row of Rough Runners—or Scarlet Runners, as they are more commonly called—must be put in, next to the Peas, if they are sown, between the Cabbages and Parsnips, pulling up a row of the former to make room. The ground for the Runners must be dug; and a drill or furrow opened by line, in which the Beans are dropped, 2 inches apart, and covered about 1 inch. When the plants have risen 2 or 3 inches they must be earthed up as high as the lower leaves. If rods can be had for this crop 6 or 7 feet in length, so much the better; but long rods are not absolutely necessary; low branches, stuck regularly along the row, about 3 feet high, are quite sufficient, providing the leading shoots are kept stopped—that is, pinching the joints off—this causing a branchy growth and great fruitfulness. But the Runner is not nice as to station; they climb up the side of a hedge or paling, cover a porch or arbour, with very little assistance. There is one thing relative to the Rough Runner which behoves every grower to know; it is, that if the pods be not regularly gathered as they become fit for use, the plants cease to be fruitful; or if they get too dry at the root, the topmost flowers drop without setting pods. But a few of the first pods should always be

allowed to ripen as seed for the next year. Attention to these particulars will render the plants fruitful for the whole season. A handful more may be planted about the middle of June, and will grow till they are killed by the frost. The dwarf sort of Kidney Bean are not worth the cottager's notice, unless he grows them to sell for pickling. The Broad Beans that were sown in January or February, among the Cabbage, may now want topping, especially if the black fly has attacked them; this will at once encourage the pods to fill, and get rid of the insects. The seed-bed of Cabbage, which was sown in March, must be looked to; and as the pieces of Radish and Turnip, which were sown at the same time, will now be used, a barrowful or two of dung should be laid on and dug in, and immediately planted with Cabbage-plants from the seed-bed. The Silesia Lettuce, sown in March, should be thinned by drawing part, to be stuck in round the edge of the Onion-bed. The plants will be ready for the purpose about the 1st of May; those left in the bed should not be nearer than 12 inches from each other, it being a very large growing sort. No directions are required by the cottager concerning Cauliflower, Broccoli, Celery, &c., these not being either necessary or profitable to him. In April, however, he may sow a small bed of Scotch Kail; which, if planted on the Onion-ground, without digging, in July, will be very useful stuff, if the winter happens to be severe. Two or three rows of Savoys may be dibbed in among or between other crops about the same time.

When the various Crops come into Use.

The crops above specified will come into use in the following order, viz., every intermediate row of the Cabbage planted in October may be used for Greens during the winter, and their places taken by Broad Beans and Peas, according as the Greens are cleared off. Next, every intermediate plant of the rows of Cabbage intended to stand to head may be pulled as wanted, to serve till the prime Cabbage come in during May and June. The Christmas-sowed Radish (if any were sown) will be ready in April; and in May there will be also the thinning of Onions, Carrots, Turnips, and Lettuce, to eke out a meal or give a relish to the rasher. Cabbage will be plentiful in May; and soon afterwards a row or two of Potatoes may be taken up; not that we would advise beginning on the Potatoes so soon, but that the ground they occupy may be had to get in upon it another crop of Cabbage, Savoys, or any other sort of Winter Greens. Another seed-bed of the Sugar-loaf or Battersea Cabbage should be sown in June, to supply Coleworts (that is, open Cabbage) during the autumn and winter; and if any piece of ground is empty at the same time, it may be sown with Turnips for winter use. If a little Leek-seed was sown among the Onions, the plants may be drawn and planted in a drill by themselves in some vacant spot, 4 or 5 inches apart, to stand for good. But if the Leek be preferred to Onions as a pottage-plant, a little bed should be sown in March, to furnish plants for putting out in rows about Midsummer. It is lucky that, in June and July, the labourer has not much to do in his garden, except gathering some of the crops, destroying weeds, and collecting everything which can be turned into manure for the service of the next season; but, in the last week of July, or in the first of August, he must not forget to sow a seed-bed of early York Cabbage, to raise plants for putting out in October and the following months. If sown a week or two before the times stated, many run to flower without forming heads; and, if sown later than the last-mentioned date, they do not come into use soon enough. About the end of August, if the duties of harvest allow, a bit of ground must be got ready at the upper end of the Potatoe ground—which crops are supposed to be taken out of the way for this purpose—three small beds, one for Onions, another for Spinach and Lettuce, and the third for Radishes. The Onions should be sown pretty thick; and, unless the winter prove very severe, the crop will be very useful in the spring, either for present use or for transplanting into an open spot of ground to bulb in the summer. The Spinach and Lettuce, if they survive the winter, will be acceptable at a time when Greens are scarce. Radishes sown in August, if the autumn is not too dry, are in fine perfection in October and November, and are then a kind of dainty. In August, too, the principal crop of Onions must be pulled and laid together thinly to dry, previously to their being roped and stored. And, when October arrives, there will be both Carrots and Parsnips, as well as the Potatoes, to be taken up and stored in safety, either in pits or otherwise; besides getting part of the same ground dunged and dug ready for Cabbages to be planted, as directed in the autumn of last year.

Plan of Garden.

Having sketched a plan for cropping twenty poles of ground with the most useful kinds of kitchen garden vegetables for a labourer or mechanic, we may now make a moderate estimate of the principal products, to show the benefits accruing to the tenant for his expenses,

time, and labour. We have supposed that the form of the garden is a long square, 38 yards in length and 16 yards wide. This area contains 608 square yards, being somewhat more than one-eighth of an acre, or twenty poles. The ground is divided into seven portions, and marked by yards lengthwise, in order to make the division easier for the tenant. The following plan shows the divisions of the garden for the first year's cropping, which are arranged as follows:—

	Yds.	Sq.	Yds.
No. 1. One yard for pot-herbs and Rhubarb, &c.	1	.	16
2. Two yards for seed-beds and Radish	2	.	32
3. Three yards for Onions, with a pinch of Leek	3	.	48
4. Three yards for Carrots	3	.	48
5. Three yards for Parsnips	3	.	48
6. Seven yards for Cabbage	7	.	112
7. Nineteen yards for Potatoes	19	.	304
	<hr/>		<hr/>
	38		608

--	--	--	--	--	--	--

Supposing the above crops are sown or planted at the proper seasons, as directed—the soil being previously prepared by digging or trenching, and manured, if possible—the crops may be expected to turn out as follows :—

Potatoes, 20 bushels, besides two or three rows taken up in summer.

Onions, 4 ditto, besides the thinnings for summer use.

Carrots, 3 ditto, besides the thinnings.

Parsnips, 4 ditto.

Cabbage, 250 full-grown, besides twice as many used as Greens.

The roots, together, make above thirty bushels of excellent vegetable-food for winter use; allowing that the bushels, one with another, weigh 60 lbs., there will be an amount of 1,800 lbs., or above 9 lbs. per day for the winter half-year. And, besides this winter store, there are Cabbages in use, either as open Greens or as full-headed, from January until June; saying nothing of Radishes, Lettuce, common Beans, Peas—all of which will be in use before the end of that period, and soon followed by early Potatoes and the Runner Kidney Beans, one of the most profitable crops a cottager can raise.

The cropping for the next year will be arranged according as is represented on the diagram, or sketch, No. 2, and which will be the easiest change; and in the third year another change may be made by placing the Potatoes in the middle, and the other crops at each end.

--	--	--	--	--	--	--

1. Herb border—2. Seed-beds, &c.—3. Potatoes—4. Onions—5. Carrots—6. Parsnips—7. Cabbage and Beans, same as preceding year.

The above plan of cropping twenty poles of ground will serve as a scale to the cottager who may have either more or less than the quantity mentioned. For instance, if he has but ten poles, then he has only half the measurement, and only half the amount of produce; and, so of any other proportionate quantity. It is to be observed that twenty poles of good ground, well cultivated, will yield a greater quantity of vegetables than can be economically used by a labourer, his wife, and three or four children. In which case the overplus must either be sold or employed in fattening a porker for Michaelmas, and a baconer for Christmas. This, with such a garden, a labourer may attempt to do, provided he has the convenience for a sty, an inclosed yard, hog-tubs, bins, &c.; and provided, also, he has a little ready-money to buy his pigs, bran and pollard to mix with the boiled vegetables, and Barley-meal to fatten off with. A pig-sty and a garden assist each other greatly; and, at the same time, a cock and two hens, of a good breed, may be kept for their eggs—a pleasant addition to the household fare.

General Rules as to Culture.

To the foregoing directions and remarks may now be added a few general rules, of which no cultivator of a garden should be ignorant.

as success depends on circumstances which are often unheeded or neglected :—First. Never work the soil, by spade or hoe, if heavy and drenched with rain, for, if moved in that state, it naturally settles down too closely together again, and remains in the worst condition for encouraging the spread of roots. Soil cannot be too dry for working ; and moving it in dry weather causes it to attract moisture from the air.—Second. Always sow in time and upon freshly-stirred soil, and while it is loose and moderately moist. Some seeds, as the common Bean and Onion, affect a firm bed to strike root in, and consequently, the first are dibbed, and the last trodden into the soil.—Third. Always plant in newly-dug ground, unless the surface be already occupied with a crop shortly to be cleared off, in which case strong plants of a succeeding crop may be profitably introduced.—Fourth. Destroy weeds before they come into flower ; and when any kind of earth or rank herbage of Grass or weeds is collected for the compost heap, see that the whole is well fermented, and turned once or twice to kill the seeds of weeds, or promote their germination before the compost is used in the garden.—Fifth. Never allow a single square yard to remain vacant during the growing season ; and that this may never be, the cottager should always have seed-beds of Lettuce, and particularly Cabbage or some one or another of the Cabbage tribe, to supply plants for both regular and irregular cropping. Although the cottager may amuse himself by cultivating a greater variety of vegetables than we have mentioned, he must not neglect the more useful kinds, for they require unceasing attention. He may, to be sure, grow Cucumbers and Pumpkins ; the first are always an agreeable relish to the bacon in warm weather ; and the second make an excellent family pie or pudding in autumn, mixed with Wildings or Crabs gathered from the hedges. A labourer may grow Cucumbers plentifully in the simplest way ; about the beginning of May he digs a pit 3 feet square, on a border lying well to the sun, making it 1 foot deep, and laying the broken earth round the sides ; this pit he fills with any rank growing weeds, Nettles, Flags, or long Grass, from the sides of ditches ; let these weeds be somewhat withered before they are shaken and trodden into the pit ; the weeds are then covered with about 10 inches of loose rich mould ; when the heat rises to the surface (if the labourer can neither beg nor buy a pot of plants from a neighbour) he may drop a few seeds in the centre of his little bed ; when the seedlings rise and have produced one rough leaf, they will require a little fresh and dry compost put round and among the stems, and the little bud at the bottom of the rough leaf pinched off. The pit is hooped over and covered every night with a mat or old sack to keep in the heat, which will continue till that of the season is sufficient. Pumpkins may be grown in the same way ; but they require the richest soil that can be got to swell the fruit to a good size.

No directions have been given about growing Cauliflower, Broccoli, Celery, Endive, Asparagus, Artichokes, and several other kitchen-garden vegetables, because these should never encumber the garden of a cottager, being to him unprofitable plants. There are, however, a few more particulars which may be of use to the cottager in the management of his garden; and first, of saving seeds. The only seeds worth his while to save are those of Onion, Scarlet Runners, Radish, and Cos Lettuce; as to Cabbage, Savoy, Carrot, Parsnip, &c., there is such risk in saving them true, and they cost so little if bought, that the amount can be no object to the buyer. When attempted, however, the finest and truest specimens of the crop should be chosen to produce seed. A few plants of Radish and Lettuce may stand where they were sown; a score of the first pods may be left on the Runners, and half-a-dozen of the best Onions planted in a row, on an open spot of the garden, in the month of February, will yield seed enough for the following season. Indeed, saving Onion-seed should be a particular object with the cottager; as having a few ounces to sell will enable him not only to buy all his other seeds, but a load or two of dung besides.

Quantities of seeds required in a small garden, viz. :—

One pint of	Peas is enough for a row of	20	yards in length.
One do. of	Beans	do.	27 do.
One do.	Runners	do.	36 do.
One do.	Dwarf Kidney	do.	26 do.
One do.	Marrowfat Peas	do.	32 do.

1 oz. Onion seed sows 15 square yards; $\frac{1}{2}$ oz., 7 square yards; 1 oz. Carrot, 15 square yards; 1 oz. Parsnip, 15 square yards; $\frac{1}{2}$ oz. of Cabbage, Savoy, Borecole, Broccoli, Cauliflower, is enough for a seed-bed of 4 square yards; $\frac{1}{2}$ oz. of Turnip sows 11 square yards; of Radish, 2 or 3 oz. for spring sowings, and $1\frac{1}{2}$ oz. for autumn; a bed of Asparagus, 5 feet by 30, requires 160 plants; an acre of Potatoes requires from 15 to 20 bushels of sets.

The above particulars will serve as rules for apportioning other kinds of seeds, according to their size and the extent of the ground to be sown or planted. We have not mentioned fruit trees; as there is not room in a cottage-garden for anything of the kind, except,

perhaps, a row of upright-growing Gooseberry trees, to be planted across the lower end of the garden; these should not be too much thinned in the pruning, but be kept in a thick bush-like form for the sake of having an abundance of fruit; all of which is to be used green for puddings and pies in the season. Ripe Gooseberries, or any other fruit, are of but little use in a labourer's family. A few Red and White Currant trees may be mixed with the Gooseberries, if desirable. —*Journal of the Royal Agricultural Society.*

THE ARBORETUM.

THE MONTEREY CYPRESS.

(CUPRESSUS MACROCARPA.)

THIS species may be regarded as the representative or equivalent of our largest European Cypress (the *Cupressus sempervirens*) on the Pacific coast of North America. Like it, it reaches a great age and a great size; its foliage is similar, and, as in it, the fruit is large and hard, differently shaped, indeed, being oblong instead of round, but of the same character, and nearer it than any other well-defined type of Cypress. It has been known since 1838, when Mr. Lambert gave the Horticultural Society a few seeds of it, without name or indication of locality. It then received the manuscript name of *Cupressus Lambertiana*, and, as it was easily propagated by cuttings, it soon got pretty widely distributed in gardens in England under that name. It was afterwards received, through Dr. Fischer, of St. Petersburg, as a new species of Cypress from California, but still unnamed and undescribed. It was next introduced in greater numbers by Mr. Hartweg, who had been sent out to Mexico and California by the Horticultural Society to collect plants for them. In sending it, he gave it the name of *C. macrocarpa*, from its large seeds, and it was described and published under that name, in 1849, by Mr. Gordon, in the *Journal of the Horticultural Society*. So it stood for a number of years, those who may be styled the old holders calling it *C. Lambertiana*, and the new holders calling it *C. macrocarpa*. But, like many other plants—we had almost said, more than most other plants—the Cypresses indulge in individual variations, every seed-bed producing peculiar modifications; and, as with other species so with this, it was soon observed that varieties showed themselves, among which the most remarkable, from their opposition of habit, were two, one growing straight and narrow, more or less pyramidal, or approaching the fashion of the Lombardy Poplar—the other more spreading, and like the Beech or the Cedar. Horticulturists, finding that they had two names and two marked varieties of this Cypress, forgetting the origin of the names, naturally set themselves to apply them to the two varieties. At first, of course, confusion became worse confounded, but gradually the gardening world have got to distinguish the two varieties, and habitually to apply the name *C. macrocarpa* to the upright-growing plants, and *C. Lambertiana* to the more spreading plants. Mr. Gordon has ascribed this difference to the first plants having been chiefly cuttings; but it is beyond doubt that the upright and horizontal varieties are both found as seedlings in beds raised from seeds of the same tree. As these two forms are generally so well marked as to

make it an easy task to assign any plants either to one or the other, it would seem that there can be no harm—nay, that it is rather desirable—that they should continue to be known by separate titles; and as it is never desirable to disturb accepted titles when it can be avoided, we should suggest that the horizontal-growing form should continue to be known by the title of *C. macrocarpa*, var. *Lambertiana*, and the upright-growing one by that of *C. macrocarpa*, var. *fastigiata*. The tree is fast-growing and beautiful at every stage of its growth, and in every form. Its verdure is exceedingly rich, dark, and luxuriant; its branches reddish; and the long whip-like shoots impart a peculiar grace to it. Unfortunately, it cannot be absolutely depended on as hardy in every position or district in this country. Notwithstanding, however, its liability to be cut off when a bad year comes, the beauty and grace of this tree, even in its young stage, are so great that we may be sure it will always hold a place around our English country houses. When killed it must be replaced. It should,

perhaps, be noted that a variety of *Cupressus Lawsoniana* (a much hardier plant) has been met with, possessing exactly the same habit and port as the *fastigiata* variety of *C. macrocarpa*; its colour, however, is not equal to that of the latter, although very beautiful in its own way; but the green of *C. macrocarpa* is peculiarly rich, and we remember no other Cypress which possesses it. It is particularly distinguished from other species of Cypress by the great size of its cones, which are nearly two inches long, and are borne in clusters of three or four. The shape and arrangement of these are well represented in the accompanying illustration. There is, we believe, a variegated variety of this Cypress; but the green form is that to which planters will, probably, attach most value.

Cones of the Monterey Cypress (*C. macrocarpa*).

Profitable Hedges.—By substituting Willow for Thorn, hedges can be made profitable; they are, it is said, more effective as a shelter, quite as strong, reared in a much shorter time, and at less than half the cost. The Willow has been recommended for hedges by Linnæus, Loudon, Miller, and other writers of note; and the only way in which the neglect of such advice can be accounted for is simply that the matter has never been sufficiently brought under notice. A Willow hedge, 200 yards long, planted in ground well dug over, cleaned, and manured—planted with cuttings 12 inches long

and 6 inches apart, requiring 1,200 cuttings, value about 25s.—became in two years a good strong hedge, capable of resisting any pressure an ordinary hedge would be subject to. The Willows being crossed diagonally, rendered it almost impossible for anything to break through. The dressings or spray of the first two years were coarse and worthless, but in the three succeeding years the dressing has sold to basket-makers for 20s. each year, which has paid the entire cost of planting, labour, and rent of land which the hedge occupies. Another hedge planted upon the same principle has, at the second year's dressing, paid the cost of the plants. The above hedges were planted with the Bitter Willow, which neither cattle, game, nor vermin will often materially injure.—*Florist.*

Spring-Flowering Shrubs.—The common Almond is now very showy in many gardens around London. *Cydonia japonica* is also blooming freely on warm sunny walls, and, its white-flowered variety is deserving of culture for the sake of variety. One of the prettiest of hardy-flowering trees, *Prunus (cerasifera) divaricata*, is now covered with milk-white sloe-like blossoms, in the grounds at Kew; and, we have likewise seen odd flowers of the richly-scented *Magnolia Soulangeana* opening their delicately-tinted petals in warm sheltered positions.

THE LIBRARY.

FLORE DES SERRES.*

IN fulfilment of the promise made in your last issue, I shall now proceed to examine and comment on the twenty-seven plates contained in the remaining triple part of this beautifully illustrated work.—Plate 1. "*Stapelia Planti*." This is a most beautifully executed portrait of this remarkably striking and handsome species. For anything like a complete collection of portraits of the varieties of this family, many of which are extremely curious and ornamental, I must refer your readers to a magnificently illustrated book in twelve volumes, imperial folio, only to be found in the library of the British Museum, and entitled "*Hortus Sempervirens Kernerii*," in which, if I remember rightly, about thirty varieties are figured. The variety here figured is said to be the most vigorous growing, and easily cultivated, of the family, and is a native of Natal, it was first figured and described by Professor Decaisne, in the "*Botanical Magazine*."—Plate 2. "*Caragana jubata*," also known as *Robinia jubata*. A most curious black-stemmed small shrub from Siberia, profusely armed at all points by innumerable long and sharp Thorns, and producing small Acacia-like foliage, and Pea-shaped flowers of a dullish shaded white, with a brownish veining towards centre of upper petal, and a blush of light rose-colour towards centre of lower one. This is, of course, quite hardy in this country.—Plates 3, 4, 5, and 6, are devoted to four varieties of Provence Roses, named respectively, Alexandre Laquenant, Ciceron, Duc D'Enghien, and Peron de Gossart. These Roses are all, more or less, dark-shaded varieties, and three of them are medium-sized, and the fourth decidedly a small flower. They are apparently (from the remarks accompanying them in the work), published by M. Van Houtte as a sort of protest against what he seems to consider the unfair preponderance of admiration and attention bestowed by the horticultural world on the Roses known as Hybrid Perpetuals, almost to the exclusion of the Provence family, which he seems to think entitled to a considerably larger share of attention than they at present receive. I do not think that the publication of portraits of these four varieties will do much, if anything, to induce the horticultural world to alter its opinion, as (independently of the Provence Roses only blooming once in the year, whereas, their rivals bloom twice, and for prolonged periods, in both summer and autumn), the blooms of the finer varieties of the Hybrid Perpetuals far exceed in beauty and brilliancy of colour, as well as in size of bloom, those of the varieties here figured, which, being put forward for a special purpose, may be presumed to be among the newest and most remarkable of the family to which they belong.—Plate 7. "*Combretum micropetalum*." From Paraguay; a very handsome free-blooming golden-flowered variety of this family, with conspicuous red-tipped stamens, which, as in *Stiftia chrysantha*, seem to form the most attractive portion of the flower. As this variety is said to do well in a cool greenhouse, it will be more welcome, to those who do not possess stoves or hot-houses, than the more generally known *Combretum purpureum*, which requires artificial heat.—Plate 8. Hardy Ghent Azalea, "*Louis Hellebuyck*." This is a most beautifully executed plate of a most lovely novelty in this ornamental family of hardy plants, raised from seed by the celebrated Belgian hybridiser after whom this variety is named, who devoted his whole life to the cultivation and improvement of this class of plants, and from whose widow the stock of this, and the five following varieties here figured, has been acquired by M. Van Houtte, who is now distributing them to the public. This variety produces fine large trusses of blooms, each of which is of unusually large size, and of a beautifully clear rose-colour on the four lower petals, with a broad and distinct white band running down the centre of each. The upper or middle petal is a most beautiful and striking contrast to the others, being of a bright and clear gold colour, tipped and edged with white. It is altogether an exceedingly fine variety, and a great acquisition to all collections of hardy plants.—Plate 9. Hardy Ghent Azalea, "*Madame Alex*." Hardy. A lovely and delicately shaded variety, producing large trusses of light rose-coloured flowers, each petal being suffused with white intensifying towards the centre.—Plate 10. Hardy Ghent Azalea, "*Mina Van Houtte*." A lovely double-flowered variety, producing rather smaller trusses of bright and clear rose-coloured flowers.—Plate 11. Hardy Ghent Azalea, "*Louis Aimé Van Houtte*." A deep carmine form of the last-named variety, producing medium-sized trusses of double flowers.—Plate 12. Hardy Ghent Azalea, "*François de Teye*." A pretty semi-double light pink flower, produced in larger trusses than either of the two last-named.—Plate 13. Hardy Ghent Azalea, "*Bijou de Gendbrugge*." A most curious and beautiful variety, producing medium-sized trusses of semi-double flowers, the outside and inside edge of the petals of which are a deep

rose-colour, and the centres and duplicature petals pure white, producing a most striking and remarkably novel appearance.—Plate 14. "*Liriodendron tulipiferum*, fol. aur. marg." A most beautifully and evenly gold-margined variety of the well-known Saddle-leaf Tulip-tree, raised from seed by Mr. F. E. Gay, of Bollwiller, on the Upper Rhine, from whom M. Van Houtte has purchased the stock. The variegation in this variety is said to be perfectly and evenly constant.—Plate 15. "*Mucuna pruriens*." A curious climbing plant, from the East Indies and Antilles, requiring the temperature of a stove, and producing immense bunches of deep purple flowers, somewhat resembling a large *Clianthus*, with red inside, and conspicuous green calices. The husks of this plant are used in Barbadoes as a substitute for sinapisms, and also when infused in beer as a remedy for dropsy.—Plate 16. "*Robinia Pseud-acacia Decaisneana*." An exceedingly delicate and pretty variety of this well-known hardy flowering tree, raised about two years ago from seed by Monsieur Villevielle, jun., of Manosque in the department of the lower Alps, who named it after the celebrated Professor Decaisne of Paris. Its flowers are produced in racemes, and are of a delicate white, shaded with pink; it is said to be free-flowering, and also perfectly hardy in this country.—Plate 17. "*Thymus Serpyllum*, fol. aur. marg." A pretty variety of golden-variegated Thyme, much resembling the variety sent out last season by Messrs. E. G. Henderson, under the name of Golden Fleece.—Plate 18. "*Hardenbergia ovata rosea*." A pretty little trailing plant, from South Australia, and requiring the temperature of a cool greenhouse. Its flowers are produced in small bunches from the axils of the leaves, the two upper petals being pure white, and the two lower ones deep pink. This plant has already been figured in the "*Botanical Magazine*," tab. 2,169, under the name of *Kennedyia* species?, and also in Edward's "*Botanical Register*," tab. 298, under the name of *Glycine* species?; it was introduced into Europe by M. A. Van Geert.—Plate 19. Trizonate Pelargonium, "*Achievement*" (Turner), one of the finest and brightest coloured of Mr. Turner's many introductions in this once popular, but now, considerably overdone family of ornamental-leaved plants, which commenced with Mrs. Pollock, which created so great a sensation when sent out by Mr. Grieve.—Plate 20. "*Pelargonium Endlicherianum*," a curious dull-red flowered variety, from Mount Taurus, of purely botanical and no horticultural interest. Why such plants are ever figured in such a work as this, I am quite at a loss to understand.—Plates 21, 22, 23, 24, and 25, represent in one fine double, and three single plates, four varieties of a most beautiful set of hardy hybrid Azaleas now being sent out by M. Van Houtte, and belonging to the variety known as *Azalea mollis glabrior*. The entire set consists of twenty named varieties of the most varied and beautiful colours, and producing flowers of large size, almost, if not quite, rivalling those of the greenhouse or Indian Azalea in beauty. Owing to the names of some of the original plants of this set having gone astray through some mischance or other, M. Van Houtte is unable at present to give the separate distinctive names of the four varieties here figured, but, as he originally possessed only a single plant of each variety, and the young plants propagated from them are kept in separate batches, he can guarantee purchasers of the set obtaining a plant of each separate variety. The first variety figured on the double plate is of a clear golden-yellow, with a distinct punctuation of bright orange on the upper petal, which adds immensely to the appearance of the flower. The second variety figured is a most perfectly-formed flower, of a beautifully clear and deep rose colour, quite the finest thing of the kind I have yet seen among hardy Azaleas. The third variety figured is a pure white, with distinct yellow spotting on the upper petal, but with a rather smaller individual flower than the last-named variety, but equally perfect in shape. The fourth variety figured is of a beautiful deep fiery-orange colour, with a lighter shading towards the centre of the flower. This flower is not quite so large in size or so perfect in form as the first-named varieties of this lovely group, but, for brightness of colour, will be a great acquisition to any collection of these plants.—Plates 26, 27. "*Malus baccata flore roseo pleno*." A most beautifully executed plate of an exceedingly ornamental and very large flowered variety of semi-double Apple, apparently most free-flowering, the outside of the petals being of deep rose-colour, while the inside and central petals are almost white. This fine variety was imported from the extreme east of Siberia; so, is perfectly hardy in this country, coming into bloom at beginning of May, and of easy propagation by grafting on the Paradise stock. This plant will be a great acquisition to every collection of hardy flowering trees.

These remarks bring to a conclusion our notice of the nineteenth volume of this beautiful work, and we have only now to look forward with pleasant expectation for the first quarter of the twentieth volume promised by M. Van Houtte towards the end of the present month.

Junior Carlton Club.

W. E. G.

* "*Flore des Serres et Jardins de l'Europe*." Parts X., XI., and XII., of Vol. XIX., Van Houtte, Ghent.

WORK FOR THE WEEK.

Flower Garden.

By means of neatness and order endeavour to render all ornamental grounds as enjoyable as possible. Walks and Grass must be frequently rolled when there is no frost, and no greater improvement could be undertaken than to make Grass verges and lawns perfectly level. We do not mean like a billiard-table or croquet-ground, but, where the ground naturally slopes, the fall should be uniform and regular. Where verges are irregular it is easy to turn back the turf and to make the ground quite level, and then re-turf, beating quite firmly with iron rammers; but do not give the edges the final trimming until such time as the Grass has taken root, and all danger from hard frost is over. Smoothness, we need scarcely remark, is one of the main constituents of beauty; therefore, a lawn which is not tolerably smooth, can never please. Turn up vacant flower-beds to the ameliorating influence of frost, and renew the soil in such as may require that being done; turn gravel walks, surface-dressing them with a coating of fresh gravel, and lay box-edgings. Frequently examine half-hardy plants protected during severe weather, and endeavour to render their covering efficient by giving additional protection when necessary; also protect bulbs during severe frost. Plant and re-arrange flowering deciduous shrubs, keeping in view ultimate effect; and, so dispose of the stronger-growing varieties as not to overgrow the more delicate kinds. Even Hawthorns, beautiful and desirable though they are, frequently occupy the front rank of mixed shrubberies when they would have been better placed further back, or set in groups; but all the stronger-growing kinds are in better keeping as park ornaments. The best for dress grounds are the different varieties of *Cratægus Oxyacantha*, as, for example, Paul's New Double Scarlet. This is a splendid variety that merits extensive cultivation. *C. O. multiplex*, the best double white, *C. O. punicea*, the finest single scarlet, and *C. O. rosea superba*, may be accepted as fair types of the kinds that will give most satisfaction. The double varieties just named are splendid subjects for pot-culture. If not already done, mulch all newly-planted trees with leaf-soil, dung, or spent tan; top-dress Hollies, Rhododendrons, and such plants as may require stimulating with rotten manure and soil. Prune deciduous plants and climbers, and train such as may require it. Mulch dwarf Roses of every description. More particularly is this necessary with such varieties as are worked on the Manetti stock. In planting Roses on this stock it is important to see that the place of union of the bud with the stock be underground. The great propensity of this Italian Briar to produce suckers, together with its tenderness, is, in our opinion, an objection to its use. We give the preference to such Roses as are grown on their own roots; these, when well-established, give less trouble and produce the best results. The more delicate varieties should be budded on the Briar stock, which is hardier in constitution than the Manetti; and we would advise the inexperienced to plant the most vigorous growers. Prune climbing and hardy pillar Roses. By pruning, we do not, however, mean the whole to be clipped over with the shears; on the contrary, use discernment in the execution of this operation. Strong-growing Roses, such as the Boursault, require well thinning out, shortening the young wood but little. Prune Moss Roses by cutting out the old wood and shortening back the young, pegging down the shoots on the beds which afford the best means of growing this Rose. Austrian Roses should have all weakly wood cut clean out and the head thinned, but do not shorten the shoots at all. Provence Roses may now be pruned, but the pruning of Roses in general had better be deferred for some time to come.

Pits and Frames.

In such as are heated, give no more fire-heat than is absolutely necessary to expel the frost, and give air as early in the morning as the state of the atmosphere will admit. Towards the middle of the month the stock of bedding-plants should be looked over; and soft-wooded plants, of which there is a scarcity, should at once be placed in a growing temperature to produce cuttings for propagation. The *Heliotrope* is well deserving of extended cultivation, and is very desirable in mixed arrangements. The finest varieties for bedding are *Etoile de Marseilles*—a star, indeed!—*Surprise*, and *Jersey Beauty*, the last very dwarf, and one of the best for bedding. As regards Geraniums in boxes and store-pots, a portion of the variegated sorts may be placed in heat when cuttings are required, but we would warn the inexperienced not to be in undue haste, as the loss of a week or two is often more than regained by the superiority of the cuttings put in later. Water carefully but effectually, so as to thoroughly moisten the ball. Cold frames containing comparatively hardy plants, such as *Gazanias*, *Centaureas*, *Echeverias*, and *Veronicas*, &c., must be attended to as regards covering when the weather is frosty. For those who have not the advantage of a propagating-pit,

employed next it, over which a sufficiency of Fern or litter may be strewed to keep out frost; during the prevalence of severe frosts and snow there is no necessity to remove the covering, as it will stand for a month, if needs be, in perfect safety; but, in such a case, inure them afterwards to light by degrees, so that the transition is not too sudden and who have to depend on heating material, now is a good time to get dung and leaves together, and thoroughly mixed, so as to become of a uniform moisture. Take advantage of wet weather to make labels and procure stakes of various sizes; trim and tie them into bundles. Wash flower-pots and store them away for potting, and see that soils are procured in sufficient quantities, and in proper condition, for potting.

Greenhouses.

At present, conservatories everywhere are gay with Camellias, Heaths, Azaleas, Acacias, *Cytisus*, *Daphnes*, *Epacris*, *Hyacinths*, and other bulbs, *Cyclamens*, *Primulas*, *Mignonette*, *Cinerarias*, *Violets*, *Callas*, *Bouvardias*, and many other things, the whole being intermixed with fine-foliaged plants, which serve to set those in flower off to good advantage. The temperature of these structures may be kept at about 45° or 50° at night, allowing a rise of 10° by sun-heat. To plants started into growth give more liberal supplies of water, and keep the atmosphere moist by sprinkling from the syringe. Introduce flowering plants from the forcing pit to take the place of those done flowering. Give air plentifully in the morning, shutting up early in the afternoon, and begin the re-potting of greenhouse plants; and, such as intend to exhibit their plants, must now be busy training, accelerating, or retarding them. Shade a little from bright sunshine Azaleas and Camellias that are in flower, and such as have done flowering, place in an intermediate temperature, and encourage them to make growth.

Ferns.

The general potting of these should have been done last month; but, if the operation has been delayed until now, it ought to be at once accomplished. If the plants have begun to grow, they will be more liable to suffer from shifting than they otherwise would be; but with careful attention in the way of shading, maintaining an equable but gradually-increasing temperature, and supplying a moderate amount of moisture, both to root and top, little danger need be apprehended. Ferns whose fronds spring directly from the soil require a richer compost than such sorts as *Davallia canariensis*, whose rhizomes grow above ground. To the former give a mixture of equal parts of good fibrous peat and loam, with the addition of some leaf-mould, plenty of silver-sand, and some small chips of fine sandstone. If the plants be required, however, for furnishing purposes, a little more loam and a little less peat will induce a hardier growth, and one better adapted for house-work than the luxuriant growth promoted by the first-named soil. Those with rhizomes above ground may be potted in fibrous peat and a little leaf-mould, pegging the rhizomes down on the soil. Some of the *Davallias*, *Polypodiums*, *Phymatodes*, *Drynaria*, and others, grow well on old stumps of Tree-Ferns, affixing themselves thereto like Orchids; if the stumps are in the vicinity of other Ferns, spores of different species are sure to vegetate in their crevices, more particularly those of *Adiantums*, *Gymnogrammas*, *Aspleniums*, and *Pterises*. Syringing Ferns is an operation requiring skill and care; for, although some genera are partial to such treatment, others are particularly averse to it, more especially the *Adiantums*, *Gymnogrammas*, *Cheilanthes*, and other delicate and farinose kinds. Filmy Ferns are best grown in glass cases, or under hand-lights or bell-glasses, or a division of the Fernery may be specially set apart for their culture. Most of the small delicate species thrive well on blocks of decaying wood, pieces of Tree-Fern stumps, or in pots; whilst, for strong-growing kinds, like the *Todeas*, pot-culture is the best and most convenient. For pot-culture, fibrous peat, chopped Sphagnum, and some fine sandstone chips make a good compost; and, for *Todeas*, the surface may be mulched with live Sphagnum. The smaller kinds of Ferns thrive well on little mounds composed of fibrous peat and sandstone chips, or on a block of wood embedded in turfy peat, from which they can emerge and scramble over the wood. These Ferns like a steady moist atmosphere, but too much artificial heat is detrimental to them; in fact, a greenhouse temperature is almost sufficient for the whole of them. In watering, let the water fall lightly upon the fronds; but, in addition to these slight sprinklings, water must also be given to the roots, more especially during the growing season. Hanging-baskets should now be replenished with Ferns and *Selaginellas*, and Wardian cases should be examined and re-filled if necessary.

A RURAL Vermont newspaper announces that its minimum charge for a first-class marriage notice will be 15 lbs. of dried Apples. Notices with "poetry" cost 12 lbs. of Onions more.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

MARCH 18, 1874.

THOUGH early-flowering bulbous plants formed the chief feature of this show many miscellaneous subjects of great interest were, also, exhibited, and the display, taken as a whole, was unusually good. Cyclamens were shown in fine condition by Mr. Goddard, and Crocuses in pots by Messrs. Veitch.

Hyacinths.—Class 1. Fifty distinct varieties. First prize to Messrs. James Veitch & Sons for a fine collection of strong, healthy, well-grown, bells. Among them the following were well worthy of notice—Single whites, La Grandesse, very fine spike; Snowball, short compact spike, pure white, massive bells; Baroness van Tuyll, silvery-white, good habit and spike; Queen of the Netherlands, very fine spike. Single blue; Prince Albert, fine purple-blue, good spike; Moltke, fine bright blue, stout spike; Baron van Tuyll, fine spike, silvery-blue; Argus, fine velvety purplish-blue, with white eye; Admiral de Ruyter, fine massive bells, strong spike. Single reds, Ornament de la Nature, fine light-rose; Solfaterre, bright-crimson, white eye; La Joyeuse, fine spike, robust habit; Garibaldi, bright shining crimson. Messrs. Cutbush and Carter, also, furnished good collections. In the class of eighteen distinct varieties, Messrs. Veitch were first with some very fine even well-grown bulbs—Czar Peter, fine blue; De Candolle, good spike, lilac; L' Innocence, fine spike, white; and others equally good. Various fine collections were also shown by private growers. In the class of six new varieties, Messrs. Veitch, who were first, furnished Cavaignac, fine robust single blue, good spike, large flowers; Grande Maître, fine single blue; Anna, robust spike of pure white flowers, of great size and substance. This variety was a gem.

Tulips.—Six kinds in twelve pots.—First prize. Messrs. J. Veitch, who had fine well-grown examples of Prosperine, fine flower, deep rosy-crimson; Rouge Luisante, yellow and crimson, flaked with rosy-lilac; Wouwerman, fine violet-purple; Vermilion, brilliant fiery scarlet-yellow centre; White Pottebakker, fine white; and Keizer Kroon, golden-yellow, flaked with deep scarlet. Second, Messrs. Cutbush, who showed Queen of Violets, fine light purple; Rose Grise de Lin, fine light rose; Prosperine Molière, fine violet; Rosa Mundi, fine rose. In the collections from private growers were also some fine flowers.

Miscellaneous Subjects.—Messrs. J. Standish & Co. received an extra prize for a group of decorative plants, including the white Abutilon Boule de Neige; white forcing Pink, Lady Blanche, a most profuse and deliciously-fragrant variety, well worth culture, and several semi-double varieties of Azalea, which are much more durable for cutting than the single kinds. The same firm also exhibited a pan of the beautiful blue Lithospermum prostratum, well adapted for forcing; and the beautiful white Tea-scented Rose Niphetos showing it to be a valuable kind for buds. A few Cinerarias with large flowers, and plants of *Æchmea miniata splendens*, a fine Bromeliad, having curved glossy leaves and spikes of coral-coloured buds. Mr. B. S. Williams staged a fine group of rare Orchids, Palms, and Ferns, and other decorative plants, to which an extra prize was awarded. The same award was given to Mr. Bull for a miscellaneous group of choice Ferns, Palms, Orchids, and Cycads. Mr. Denning exhibited a nice group of winter-blooming Orchids, from Londesborough Lodge, including specimens of *Cymbidium eburneum*. Messrs. Veitch staged a remarkably choice group of Orchids, including many rare and valuable species; *Odontoglossum Caradeni*, pale yellow sepals and petals, and lip narrow, spotted with brown; *Miltonia Warscewiczii*; *Odontoglossum Pescatorei*; *O. Andersonianum*, a profuse purple-spotted form of *O. Alexandræ*; a nice plant of *Angræcum sesquipedale*, bearing eight of its white wax-like flowers; *Miltonia cuneata*, with sepals and petals of a dark brown colour, the heart-shaped lip pure white; a fine plant of the rare and beautiful *Dendrobium Wardianum*, with two fine flowering-bulbs; *Vanda cœrulescens*, a pretty little blue-flowered species, well worth general culture; *Cymbidium eburneum*, and other species; together with plants of *Odontoglossum triumphans* and the brown-speckled *O. odoratum*. An extra prize was deservedly awarded to this fine group. In class 10, for six distinct Orchids, Mr. B. S. Williams was first with fine specimens of *Dendrobium Wardianum*, *Renanthera coccinea*, *Dendrochilum glumaceum*, *Phalænopsis Schilleriana*, *P. grandiflora*, and a yellow *Oncidium*. Mr. W. Bull was second with *Masdevallia Lindenii*, *Phalænopsis grandiflora*, *Cypripedium villosum*, *Lycaste Skinneri*, and others. Class 9, six Orchids.—First, Mr. Denny, gardener to Lord Londesborough, with *Odontoglossum Andersonianum*, a fine sub-variety, differing in the spots being conglomerated in the centre of each segment; *Dendrochilum glumaceum*, a very fine well-grown specimen, profusely bloomed. A remarkably well-grown specimen of *Cymbidium eburneum*, with thirteen fine flowers. The rare *Odontoglossum coronarium*, bearing a robust spike of eighteen flowers, sepals and petals of a bright reddish-brown, looking as if varnished; margined with yellow; lip, pale yellow; and a small but well-bloomed plant of *Cœlogyne cristata*. Mr. W. Paul, of Waltham Cross, staged six boxes of cut Roses of remarkably fine quality for the season, and an equal number of stands of Camellias. The effect of these two popular flowers being shown in the same manner and together was very remarkable, and is a convincing instance of the manner in which nature's times and seasons are controlled by art. For the prizes offered by Messrs. Barr & Sugden, there was only one exhibitor, Rev. W. Kendal, East Sulworth, Dorset, but Messrs. Barr & Sugden set up a neat box containing a dozen varieties. Messrs. H. Lane & Sons, Berkhemstead, staged a dozen fine specimen Ivies in pots, including the following varieties: Golden, creamy variegation; Digitata, slender-growing green-leaved variety; Rægneriana large,

glossy, heart-shaped leaves, very distinct; *Caenwoodiana*, fine slender palmate-leaved variety, green, with silvery veins; *Maculata*, green, blotched with creamy white; *Himalaica*, distinct green-leaved form with jagged margins; and *Canariensis maculata*, green, splashed with creamy white. Messrs. W. Rollisson, of Tooting, staged a very interesting group of stove and greenhouse decorative plants, including Palms, Ferns, *Dracænas*, Orchids, succulents, and *Ericas*. In this group the plants of *Erica elegans*, *Adiantum cristatum*, *Brainea insignis*, and a pair of *Dieffenbachia Bauseii*, were well worth notice. Mr. R. Dean, of Ealing, staged a fine collection of hardy Primroses, including varieties with crimson, white, purple, yellow, sulphur, lilac, and violet flowers, and a miscellaneous selection of spring-blooming herbaceous plants, including *Scillas*, Pansies, *Hepaticas*, *Myosotis dissitiflora*, *Arabis albidia* var. *præcox*, *Narcissus Trumpet-major*. Mr. Robert Parker, of Tooting, staged a fine group of spring-blooming herbaceous plants, amongst which the following were specially worth notice:—*Erythronium Dens-canis*, with nodding lilac flowers among its brown spotted leaves; *Polygonatum multiflorum*, remarkably well adapted for spring forcing; and, as a plant for furnishing cut flowers, *Anemone Pulsatilla verna*, with feathery deep green leaves, silvery bracts, and deep purple flowers; the deep blue *Scilla sibirica*, *Dielytra spectabilis*, *Muscari botryoides*, with flowers of the brightest cerulean blue, together with its pure white variety—*M. racemosa*, *Iris reticulata*, and many others. Many herbaceous plants are so well adapted for decorative purposes in pots, and are so easily grown that it is a matter of wonder that we so seldom see them cultivated for this purpose. Mr. Ware, Mr. Parker, and Mr. Barr have often shown us how easy this is to do, but we are slow to follow even such excellent examples.

Fruit.—In the class for two bunches of black Grapes, Mr. W. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Winchfield, was first, with two clusters of Lady Downes, in fine condition; second, Mr. W. Cole, gardener to J. Budgett, Esq., Ealing Park. Mr. J. Douglas staged Lady Downes in this class, with fine berries. In Class 30, for three kinds of dessert Apples, there was spirited competition, and the first prize was obtained by Mr. C. Roe, Welford Park, Newbury, with fine specimens of Cox's Orange Pippin, Scarlet Nonpareil, and Cornish Aromatic; second, Mr. T. Jones, Royal Gardens, Frogmore, with Cox's Orange, Blenheim Orange, Claygate Pearmain. In the class for kitchen varieties, Mr. F. Parsons, gardener to R. Attenborough, Esq., Turnham Green, W., was first, with fine Wellington, Blenheim Orange, and Alfriston; second, Mr. W. Gardiner, gardener to E. P. Shirley, Esq., Stratford-on-Avon, with Blenheim Orange, Yorkshire Greening, and Gloria Mundi. In Class 32, for Pears, Mr. T. Jones, of Frogmore, was first, with Beurré Rance, Chaumontel, and Shobden Court; second, Mr. A. Parsons, gardener to W. J. Blake, Esq., Danesbury, Welwyn, with Fondante de Mons and Uvedale St. Germans. A collection of dessert and Kitchen Apples, sixty-five varieties shown by Mr. S. Ford, gardener to W. E. Hubbard, Esq., Leonard's-Lee, Horsham, deservedly gained an extra prize. This collection was very remarkable for the time of the year.

Vegetables.—Vegetables, including Mushrooms, Cucumbers, Asparagus, and Broccoli, were limited in quantity, but of fair average quality. Mr. E. Cooling, of Bath, was first for Broccoli; Mr. T. Record first for Mushrooms; Mr. J. Douglas for Cucumbers; Mr. E. Clarke, of Sutton, Surrey, for Seakale; and Mr. James was the only exhibitor of Asparagus, the quality being excellent.

First-class Certificates were awarded to the following:—

Polyanthus The Bride (Dean), a very smooth pure white variety, valuable for spring bedding.

Primrose Splendour (Dean), a very profuse-blooming variety, well worth general culture.

Chysis Chelsoni (Veitch).—This is a very interesting cross between *C. bractescens* (a white-flowered species) and *C. Limminghii*, a rosy-petalled species, with a crimson-veined lip. It has been raised by Mr. Seden, and bears great yellow salmon-shaded flowers.

Cypripedium Argus (Veitch).—This is from the Philippines, and is possibly a natural hybrid between *C. barbatum* and *C. venustum*, but it is more profusely blotched than either. It has the slender-edged petals and foliage of *C. barbatum*, while the sepals are green-striped, like *C. venustum*.

Hyacinth Cavaignac (Veitch), a fine porcelain blue flower, closely set on a fine stout spike.

H. Sir S. Plimsol (Veitch), fine spike with finely-formed waxy bells, white, slightly suffused with blush.

H. Anna (Veitch).—This was the finest variety shown, with great waxy bells, fully 2 inches across, borne on a stout spike with good foliage.

H. Quisine Christine (Veitch).

Polyanthus Narcissus (Veitch), a very robust form, distinct from the Roman, bearing nine to ten sweet-scented flowers on a scape.

Cattleya Veitchiana (Veitch), a very beautiful hybrid, raised by Mr. Dominy, between *C. crispa* and *C. labiata*. It has a fresh and vigorous habit, and large showy flowers, in shape like *C. crispa*, but with rosy-lilac segments, and a crimson-blotched lip, like *C. labiata*.

Rose Madame François Janin (Bennett).—This is something like *Madame Falcot*, of a golden-yellow, shaded with salmon, and is very beautiful in the bud for cutting. The foliage is perfect.

Rose Madame Lacharme (Bennett).—This is a fine Rose, of robust habit; but it must rather have disappointed those who have so often heard it described as pure white. It is the colour of the Maiden's Blush, and undoubtedly a fine variety that will be largely grown.

Messrs. J. Bromwich exhibited a very interesting assortment of plant-cases and aquaria, made on improved principles, and well worth notice.

ERRATUM.—By a clerical error of one of our transcribers, our last week's note, headed "Hardiness of the Chinese Arbor-vitæ" (see p. 232), misrepresents what we intended to convey. It should read thus:—"Mr. Sargent, of Boston, informs us that while thousands of the *Juniperus virginiana*, or Red Cedar, were killed in the Northern States by the frost of 1871, the Chinese Juniper (*J. chinensis*) everywhere escaped."

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE BEST VARIETIES OF STRAWBERRIES, AND THEIR CULTURE.

By WILLIAM TILLERY, Welbeck.

HAVING grown an immense quantity of both old and new varieties of Strawberries, perhaps a list of those which I consider the best, accompanied by some remarks concerning their culture, may be of use to intending planters. Let us commence with the Black Prince, which is one of the earliest; although it possesses but little flavour it is a great bearer, and useful for gathering for preserving. Viscomtesse de Fleury is another prolific and early sort, and I find the old Scarlet still one of the very best for growing in quantities for preserving, and, being a very early ripener, it often comes in for that purpose, when the later sorts are spoiled by heavy thunder showers in July and August. As regards mid-season varieties, Sir J. Paxton is a first-rate kind, and carries well. The old Keen's Seedling is still not superseded as a good early kind for forcing, but it requires a careful selection of the plants, as they often get quite barren in plantations of more than three years' growth. Rivers's Eliza is a prodigious bearer, and I find it is a kind that produces better crops in light soils than many other Strawberries; it, likewise, comes in very useful for preserving. During the past season, President has been one of the very best bearing kinds in our collection, the beds being literally paved with trusses of its fruit. The trusses of this kind, too, are so heavy that they require extra care in propping them up, for, if this is not done, the fruit rots when covered by the foliage. Sir Charles Napier is still one of the most profitable varieties for the market-gardener to grow, for, though a little acid in flavour for the dessert, it is good for preserving, carries well, and is likewise a sure bearer. La Constante is a very dwarf grower and makes few runners, but the fruit has a peculiarly rich flavour, and is very good either for dessert or preserving. In the strong loamy soil of the garden here this variety always bears well, without renewing the beds so often as others. Ingram's Prince of Wales has medium-sized deep crimson fruit, which are of the most juicy and refreshing flavour of any kind I grow, and the plants, likewise, bear well. Lucas, a new Belgium variety, is, I find, an excellent bearer, the fruit, very large and of a fine conical shape, with very good flavour. Rifleman, a variety raised by the late Mr. Ingram, is an excellent large-fruited sort of good flavour, and carries well. Marguerite, a French kind, I have discarded, for, although its fruit is very large, the texture of the flesh is watery, with little flavour. Empress Eugénie is another large coarse-fruited kind, which I have likewise discarded, on account of its want of flavour, but it forces well, and is showy in a collection. Of the latest-fruited section of Strawberries, Dr. Hogg is still the best, both as regards size and flavour, and it is closely followed by British Queen and Mr. Radcliffe. On the strong loamy-soil, mixed with burnt red clay, in the kitchen garden here, these three varieties always bear well, and the plants seem healthier than in lighter soils. Cockscomb is another very large new kind that does well in strong soil, but its flavour is not first-rate. The Amateur is a new kind of the Sir Charles Napier type; it is a prodigious cropper, and its fruit large and of good flavour, and, as it travels well, it will make a first-rate kind for growing for the market. Comte de Paris is a French late variety, the fruit very large and handsome, but rather acid in flavour, though excellent for preserving. Frogmore late Pine is the best flavoured of all the late sorts, but it is only a shy grower, and requires good rich soil to make it bear well. The Elton is still the latest sort grown, and is one of the very best for preserving, its flesh being very red and firm, and the fruit large.

Culture.

In the culture of Strawberries, the best results will generally be obtained where the soil has been trenched or deeply dug, and enriched with plenty of good rotten manure; and the beds or rows are not profitable when allowed to remain longer than

three years on the same soil. A good strong loamy soil is the most suitable for the plant, but as this is not found in every garden, a mixture of stronger soil can be added to a light soil, where good crops of Strawberries are a desideratum. Plants of Strawberries which have been forced in pots, will, if planted out in a rich sandy soil, produce excellent crops, for the ball of strong soil at their roots will make them bear well for, at least, two years after being planted out. I raise all my best crops from pot plants when planted out, as early as possible after the fruit is gathered. In general, the plants, after forcing, are huddled together, and often neglected in dry weather as regards water, and not planted out till the pots are wanted again for the newly-laid young batch of runners. This does not give the old plants so good a chance of rooting into the new soil as when they are planted out early. When the weather is favourable in autumn, some of the varieties, when planted out early from pots, produce good second crops of fruit. In planting young plantations of Strawberries from runners, they will be found to succeed best when planted in July or August, for then they have time to root well before the winter sets in; and, if the runners have been strong when planted, they will produce some fine fruit the year following. When the planting of the runners is delayed till the spring, dry weather often prevails in March or April before the roots have progressed much, and a year is lost as regards getting much fruit from them. Late autumn-planting is, likewise, wrong in practice, for the early frosts heave the plants out of the ground unless well protected with litter. I find that a top-dressing of litter put on in the autumn as a protection against severe winter frosts is requisite for Strawberry beds, whether newly planted or not. In the spring the young leaves grow through it, and the strawy litter keeps the fruit clean after the heavy rains or showers. This is better than using tan, short Grass, or hay, for this purpose, as seeds are shed in the ground, and take labour to eradicate them again. In dry summers, Strawberry plants, when swelling their fruits, will enjoy any amount of liquid manure.

French Mode of Culture.

The varieties of Strawberry chiefly grown in France are those known as the Quatre-saisons and the Caprons. The former is a highly-developed form of the common wild Strawberry of our woods (*Fragaria vesca*), which, under cultivation, has acquired the character of producing a long-continued succession of fruit of excellent quality. The Caprons, in like manner, have sprung from the equally well-known, if rarer, Hautboy (*Fragaria elatior*), and exhibit, in a marked degree, the influence of carefully-directed cultivation in ameliorating the wild products of nature. The Caprons are distinguished from all other species or varieties of Strawberry by their strong peculiar musky flavour and perfume; and, it may be remarked, are to other kinds of Strawberry what the Muscats are to other kinds of Grapes. In the neighbourhood of Paris the variety most grown is the Quatre-saisons, and the following account of its culture at Versailles, extracted from the Count de Lambertye's treatise on the Strawberry, will be found interesting:—"The plants are all raised from seed, which is sown early in March under frames. In the beginning of May the seedlings are pricked out in lines in the open air, with a distance of 8 inches from plant to plant. The runners which issue from these are separated and transplanted into a bed, from the middle to the end of August, the same distance being maintained from plant to plant. In both cases the soil is well mulched. The flower-stems and runners of the plants in the bed are rigidly suppressed. The final transplanting is made in the middle of October, when the plants are removed into a moderately-manured well-dug bed, in an airy position. Four lines are drawn in the bed, at a distance of 14 inches from each other, and in these the plants are inserted alternately, with a space of 16 inches between them. In the following spring, the surface of the bed is well hoed, and then mulched; the flower-stems are not suppressed, but the runners are removed now, and again in the autumn, after the crop has been gathered. Each bed is allowed to bear only for a year and a half, and the plants are dug up and thrown away in the autumn of the second year. It is remarked that the plants raised from seed are not so productive as those raised from runners, but the fruit has a much finer flavour."

NOTES OF THE WEEK.

— WE learn, from the *Revue Horticole*, that seeds of that charming hardy ornamental shrub, *Xanthoceras sorbifolia*, have been freely distributed by the authorities at the Muséum. We may, therefore, expect that the time is not very distant when we shall see its lovely flowers add a new grace to the gardens and pleasure-grounds of this country.

— MR. NOBLE, of Bagshot, has obtained permission to hold an exhibition of Clematises this season in the Royal Horticultural Society's Gardens, at South Kensington. The exhibition will consist of some 2,000 plants, and, as a large number of these will be seedlings, flowering for the first time, great variety may be expected. The exhibition will remain open about a month.

— AT the Royal Botanic Society's Exhibition, held on Wednesday last, Mr. Needle, gardener to H.R.H. the Comte de Paris, at Twickenham, exhibited a fine collection of hardy Orchids, some of which were British species of *Orchis* and *Ophrys*, others came from Spain, southern France, and the Alps. Though not very showy in the ordinary acceptance of the term, still such plants are highly interesting to those who examine closely the smaller and more curious vegetable forms. We were pleased to see that these little plants were greatly admired, especially by lady visitors.

— AT a sale of Orchids, imported and established, which took place at Stevens's the other day, plants of *Odontoglossum Roezlii*, just received in excellent condition from Messrs. Backhouse's collector in South America, fetched £7 7s. each; a strong plant of *O. vexillarium*, £11; *Oncidium macranthum*, unusually fine, £10 10s.; *Cattleya exoniensis*, £10; a fine mass of *C. citrina*, £10 10s.; a fine plant of *Cypripedium lævigatum*, £12; *C. Parishii*, £11 11s.; *C. caudatum*, £9 10s.; *Lælia elegans Turneri*, £16 5s. 6d. Other lots, of which there were some 424, fetched from 10s. to £5 per lot.

— WE (*Tribune*) are informed that the Assembly of Iowa has appropriated 1,000 dols. (£200) for the best new Apple that will keep in good condition until after April 1, and for a superior Plum improved from native stock, the same to be a variety not now in existence, and superior to any in hardiness, productiveness, and quality of fruit. The seedlings must be exhibited from year to year before the State Horticultural Society, and the premium is to be awarded in 1886 by a competent committee appointed by that association.

— THE *Scientific Press* of San Francisco gives a picture, taken from a photograph, of a Rose bush in Santa Rosa, which is 25 feet high, 22 feet across, with 4,000 full-blown Roses, and 20,000 buds upon it. It was planted in 1858, and is of the Lamarque variety, one of the most beautiful of white Roses. The stem, near the root, is 24 inches in circumference, and just above the ground it divides into three principal stems that grow over 12 feet without lateral branches. These main branches pass between a strong support and the eave of the cottage against which the bush is trained. If the queen of flowers flourishes in that way in Santa Rosa, that city has by no means an inappropriate name.

— THE last number of the *Revue Horticole* contains a coloured plate and a description of a very handsome *Clerodendron*, called *C. imperiale*, of which M. Carrière is in doubt as to whether it is a species, a hybrid, a variety, or simply an old plant re-juvenised. It forms a pretty and very distinct shrub from 6 to 7 feet high, with a bare stem which seldom branches. The leaves, which are almost whorled, are borne on long petioles, and are about 1½ feet in diameter, broadly ovate, pointed, and of the tenderest green. Above them rises the thyrsoid panicle of Poppy-red flowers, some 3 feet in length, the effect of which must be seen to be properly appreciated. The figure of the plant in the *Revue* recommends it strongly to the notice of cultivators.

— THE Royal Commission on Scientific Instruction and the Advancement of Science has issued its fourth report, which deals with the national museums, and contains a series of valuable suggestions for making these institutions more serviceable. In view of the removal of the natural history collections of the British Museum to South Kensington, the commissioners recommend the appointment of a director of these collections who should be responsible to a Minister of State. The botanical department of the museum, they think, should be arranged with reference to the geographical distribution of plants, while Kew Gardens are to remain as they are. They recommend, however, that increased opportunities for the study of physiological botany should be afforded in the Royal Gardens at Kew. Perhaps the most important suggestions of the commissioners are the two following:—"That, in connection with the Science and Art section of the Education Department, qualified naturalists be appointed to direct the collection of specimens in order to supply whatever deficiencies exist in the more important provincial museums; and, also, in order to organise typical museums, to be sent by the Department

of Science and Art into the provinces, to such science schools as may be reported as likely to make them efficient instruments of scientific instruction." And "that the establishment of lectures on science, accessible to all classes, on the payment of a small fee, should be promoted by the government in the great centres of population."

— IN the gardens of the Muséum, at Paris, a little-known species of *Amaryllis* (*A. calyptata*) has recently flowered. This plant is a native of Brazil, and bears a flower-stem about 2 feet high, terminating in two opposite yellowish-green flowers, at the base of each of which are two bracts of the same colour as the flowers. The plant has little in itself to recommend it, but may prove useful to hybridisers.

— M. GRANGE, of Orleans, has recently sent out two new plants, namely, *Clematis lanuginosa purpurea* (a cross between *C. lanuginosa* and *C. viticella*), which has quite a new and distinct shade of colour, with flowers nearly 5 inches across. The other plant is a very free-flowering *Phlox*, named by the raiser *Boulevard-feu*. It grows about 2 feet high, and bears a profusion of large fiery-red flowers.

— WE notice that an attempt is being made to improve Soho Square. Anything is better than the neglect which it has hitherto displayed, but we are sorry to see that the march of improvement has taken the ill-advised step of planting the inevitable Privet-hedge inside the railings. Soho Square might be made attractive, but, until our city squares are thrown open to the public, their internal decoration is not so important as it otherwise would be.

— PLANTS of a Grass, or rather Reed, called in South America *Taquarussa*, are living fountains. They grow, says Dr. Schomburgk, from 30 to 40 feet high, with a diameter of 6 inches, form thorny impenetrable thickets, and are exceedingly grateful to travellers and hunters; for, on cutting such reeds below a joint, the skin of the younger shoots is found to be full of a cool liquid, which quenches the most burning thirst.

— AMONG the new plants advertised by MM. Fröbel & Co., Neumünster, Zurich (Switzerland), is *Begonia octopetala*, a species recently introduced from the Andes of Peru. It is very robust in habit, and has large orbicular leaves, and flowers over 3 inches across, with eight broad white petals, the backs of which are of a bright carmine-red. This plant is said to be sufficiently hardy to be planted out-of-doors in summer.

— VARIOUS Hyacinth shows are now being held in different places. One, in all respects excellent, may be seen at Messrs. Veitch's, in the King's Road; another at Messrs. Cutbush's, Highgate; and a third at the Crystal Palace, where, besides Hyacinths, Messrs. Downie, Laird, and Laing have a fine display of other plants, occupying staging 100 feet in length. The centre consists of Palms, Azaleas, the variegated *Acer Negundo*, *Spiræas*, and *Dielytras*, supported by such plants as *Cyclamens*, *Chineses*, and other Primroses, and Tulips, the whole making a display well worth inspection.

— NO FEWER than four new hybrid Orchids were exhibited by Messrs. Veitch & Sons at the Royal Botanic Society, on the 25th inst. These were *Dendrobium Dominii*, *Cattleya Veitchiana*, *Lælia Veitchii*, and *Chysis Chelsonii*. It may interest some of our readers to know that *Cattleya Veitchiana* was raised by Mr. Dominy no less than sixteen years ago, and has now only just opened its richly-tinted flowers for the first time. *Dendrobium Dominii* is specially interesting as the first hybrid *Dendrobe* raised, and all the others are distinct and equal, if not superior, in one or two cases, to existing forms.

— A MR. CAMPBELL, says the *New York Tribune*, claims to be able to ascertain in advance the qualities of seedling Grapes. He says that "in the taste or flavour of the green tendrils of the Vine may be found a true index of the character of its prospective fruit." He further declares that the tendrils of each variety possess a distinguishing flavour, by which it may always be detected from any other, and a seedling with this peculiar character may be at once set down as good, even in advance of its crop. His predictions are said to have been verified in every instance, and frequently, too, when the appearance of the foliage would lead him to an opposite conclusion.

— SEVERAL winters of late years, says Mr. McNab, have been remarkable for their mildness, but more particularly the last one, many parties boasting of the bouquets which they have been able to collect from their open gardens. The Gloire de Dijon and other Roses have been flowering freely both on walls and in the open ground, and during the whole winter, even up to the present time, many scarlet Pelargoniums and other summer bedding plants, planted last spring, are still alive. From the reports laid before the spring meetings of the Botanical Society of Edinburgh, it will be observed that the past winter and spring, up to this date (March 12), have produced more open-air flowering-plants than any previous season known to me, showing that, if our summers are not so warm as they used to be, our winters are, seemingly, much milder.

THE INDOOR GARDEN.

SEAFORTHIA ELEGANS.

Few of the larger-growing Palms equal this species in beauty; and it has, what is in many cases a great advantage, the property of being a rapid grower. Its proper place is planted out in a conservatory that is cool in summer, and kept regularly a few degrees above freezing in winter. Planted out in such a position in a bed of rich loam, and abundantly supplied with moisture, it soon makes a noble plant. Although a native of tropical Australia, it is sufficiently robust in constitution to succeed out of doors as a sub-tropical plant during our summer season, when it should be plunged on a well-drained bottom. Our illustration, showing the way in which it is used in French gardens, exhibits the graceful port of this species at a glance, and also the singularly effective character of the plant when associated with Yuccas and other fine-foliaged subjects in the open air. Scarcely any other Palm is better adapted than this for a centre plant in any well-arranged group of foliage or flowering plants; and small specimens are useful for this purpose, as well as for the decoration of apartments and reception-rooms. It is readily propagated from seeds sown in light soil in pots plunged in a gentle moist bottom-heat, and the plants are ornamental from the time they attain 9 or 10 inches in height until they outgrow the quarters allotted to them. Frequent syringings overhead are beneficial to them, especially during hot weather, in order to keep down red spider, and as soon as the pot or tub becomes filled with roots, a little manure-water is advantageous to them. Being readily propagated, it is reasonable in price; no one, therefore, need be without it on that score. We have noted several small plants doing well in apartments, but they require a plentiful and regular supply of water at the root, and the hard foliage should be washed at least once a week with a soft sponge and clean tepid water. If soap is used, be particularly careful to remove every particle of it from the plant afterwards, by either syringing or sponging with clean water. If only one Palm is required for either pot culture or for planting out in the conservatory, we should recommend this before all others, on account of its graceful habit and easy culture. Q.

Seaforthia elegans.

THE FLAMINGO PLANT.

(ANTHURIUM SCHERZERIANUM).

NEARLY every plant-grower is tolerably well acquainted with the many excellencies possessed by this beautiful decorative plant, and it deserves even more extended cultivation than it now receives. Few decorative plants have improved under culture so much as this singular Arad. It is a native of Guatemala and Costa Rica, growing in moist positions, and bearing very small spathes, rarely over an inch long, among the dwarf herbage by which it is surrounded. Indeed, so inconspicuous is the plant in its native habitat, that collectors have passed it time after time, not considering it showy enough to be worth introduction. It was exhibited at South Kensington by M. Wenland early in the summer of 1862, but did not receive much attention at the time, and the figure in the "Botanical Magazine," of June, for the same year, is a correct representation of the inflorescence as it first developed itself under cultivation in this country. Liberal culture has, however, worked wonders, and, instead of the little "brick-red" spathes, only an inch in length, accompanied by foliage small in proportion, we now have fine forms bearing spathes from 5 to 7½ inches in length, and 3 to 5 inches in breadth, the colour being of the brightest shining scarlet or vermilion colour imaginable. Instead of taking the horticultural world by storm at first, and gradually sinking in public estimation, after the manner of many other new plants, this has gradually, but surely, won its way into popular favour, and is now to be found by the dozen in many private gardens, while some of our leading nurserymen have it in stock by the thousand, to meet the ever-increasing demand from amateur cultivators.

Propagation.

One thing likely to make this plant popular amongst small growers and amateurs is the ease with which it is multiplied, either by seed or division. Old and well-established specimens frequently bear abundance of seed without any assistance from the cultivator; and, seed so produced rarely fails to germinate very freely, sown in shallow well-drained pans of light sandy compost. If placed in a close case, on a gentle bottom-heat, germination will take place much sooner, and the pan should not be disturbed, for the young plants will continue to make their appearance for a year or two after the seeds are sown. The young seedlings may be removed as they develop themselves, and, if pricked off into other pans,

or potted singly in small pots, they soon increase in size and vigour. Sometimes it is necessary to assist the plants by artificial fertilisation in order to obtain seed, while in other cases plants seed themselves spontaneously, without any assistance at all from the cultivator. In order to induce fruitfulness, all that is required is to remove the pollen from the spadix of one plant to that of another, and the best way of effecting this is by the use of a camel's-hair pencil, slightly moistened in honey so as to cause the pollen grains to adhere. After fertilisation, the seeds are, at least, a year in arriving at maturity, and, when ripe, the scarlet berries start from the flower-spike and hang down at the sides, being held by two or three little white filaments. When they are ripe it is best to sow them at once, treating them as above recommended. The plant can, also, be propagated by the division of large specimens, or by removing the offsets, which are somewhat freely produced around the base of the old stools.

Culture.

This plant can be grown by everyone who has a plant-stove; or, even in a warm greenhouse, it does remarkably well if liberally treated. It likes a warm temperature and plenty of moisture at the root all the year round; indeed, any attempt to induce the plant to rest in order to promote the production of its bright spathes is sure to result in failure. The compost best suited to this plant is the same as that used for many sub-terrestrial Orchids, viz., fibrous-peat, in lumps as large as pigeon's eggs, living Sphagnum Moss, mixed with broken crocks, leaf-mould, and sufficient coarse well-washed sandstone grit, to keep the whole open and porous. The plant must be well-drained, and, if possible, induce the Moss to grow freely on the surface of the compost. In potting, take care to elevate the plant well above the rim of the pot, and the addition of a little more compost and Moss is desirable, as the plant roots out above the pot. The plant is not subject to many insect pests, but, like all other hard-leaved plants, it should be repeatedly sponged with clean water, to remove dust and other impurities, while frequent and regular syringings with tepid water promote its healthy growth and vigour. The plant grows very freely when its requirements are duly attended to, and, in the case of vigorous specimens a little stimulant, in the way of weak liquid manure, is beneficial.

Varieties.

We know that most plants raised from seed vary considerably, not only in the shape and size of their foliage and floral organs, but, also, in constitutional vigour. This is especially the case with the plant in question, for we have several distinct varieties readily distinguished, at a glance, by minor differences in size or colour of the scape and leaves. In the case of Roses, Pelargoniums, or other florist's flowers, these would have received distinctive names ere this, but, at present, we have only one or two so honoured.

A. SCHERZERIANUM, var. DIXONII.—This is a peculiar abnormal variety, tolerably free in its growth, differing from the other forms in having a curious double spathe. It does not come true from seed, but can be readily multiplied by division.

A. S. ALBA.—The white-spathed variety of this plant is not yet distributed by its fortunate possessor, but it cannot fail to become a general favourite when generally known. In habit, the plant is like the normal forms, but the spathe is of milky whiteness, with a bright orange-coloured spadix. As an exhibition plant it cannot fail to be invaluable as a striking contrast to the scarlet-bracted forms. I can readily imagine many things as likely to occur in horticultural philosophy, but the advent of this snowy beauty took me quite by surprise, since I never heard a whisper as to its existence until I was ushered into the presence of a flowering plant by its lucky introducer.

A. S. MAGNIFICA.—This is the best variety, having very large, thick, deep green leaves, deflexed from the petiole, and it bears spathes 6 to 7 inches long, and of a proportionate width, while, in colour, they are of the most brilliant scarlet imaginable. Fine specimens of this noble variety have repeatedly been exhibited by Mr. T. Baines, Messrs. Cole, of Withington, and many other noted exhibitors. There is no comparison between

this variety and some of the others which have erect, narrow, dry-looking foliage, and small dull-coloured bracts. Good plants of this variety frequently bear from twenty to fifty great scarlet spathes, forming one of the finest and most effective of all exhibition plants in cultivation. There is another excellent variety with narrower leaves and smaller spathes, about 4 inches long by $2\frac{1}{2}$ to 3 inches wide. This plant, like the last-named form, has a robust and vigorous constitution, and is very profuse in the production of spathes. I once saw a plant of this nearly a yard across in the collection of Mr. Sigismund Schloss, Bowdon, Cheshire, and this plant bore upwards of a hundred of its showy bracts. At least one plant of each of the above should be grown in every collection of choice stove plants, however select.

F. W. BURBIDGE.

Dendrobium Boxallii (Rchb.)—The more we know of Orchids, the more are we perplexed by their affinities, and, in some cases, shadowy differences. The present plant, however, is quite distinct enough to constitute a species, though, in most respects, it closely resembles others already generally in cultivation; still, its chaste beauty cannot fail to make it a favourite when better known, especially as it flowers most profusely. I received notice of its having flowered in three collections nearly simultaneously, viz., with O. O. Wrigley, Esq., Bridge Hall, Bury; Messrs. Low & Co., Clapton; and with Messrs. Veitch, Chelsea, the last being the first to exhibit blooming specimens of it at South Kensington on the 18th February last. In general habit it most nearly resembles *D. Wardianum*, having stout knotted bulbs, which vary from 1 to 3 feet in length, and which are pendulous. The flowers are borne on the leafless bulbs of the preceding year, and generally in clusters of two, rarely three, together. The individual flowers vary in size on different specimens, the largest being about $2\frac{1}{2}$ inches across. Sepals and petals, pure white, tipped with bright rosy-lilac or pale magenta. The lip is nearly round, with a large circular blotch of pale orange-yellow in the centre, the apex tipped with pale magenta. In general appearance the flowers are nearly exactly intermediate between *D. crystallinum* and the knottystemmed *D. crassinode*, but they are, in most cases, larger and more brighter coloured than those of either of those species. I have counted fourteen flowers on a bulb 15 inches long in the Clapton Nursery, and it flowers equally freely elsewhere.—F. W. B.

Orchids now in Flower at Oakley House, Gledhow, Leeds.—*Angræcum eburneum*, *Calanthe Masuca*, *C. nivalis*, *C. Turneri*, *Cattleya labiata*, *C. Trianae*, *C. T. albida*, *Cœlogyne cristata*, *C. alba*, *Cypripedium hirsutissimum*, *C. Hookeræ*, *C. Lowii*, *C. Roezli*, *C. Schlimii*, *C. venustum*, *C. villosum*, *Dendrobium Boxallii*, *D. Dayanum*, *D. heterocarpum*, *D. Infundibulum*, *D. Jenkinsii*, *D. lituiflorum*, *D. macrophyllum*, *D. moniliforme*, *D. nobile*, *D. n. pendulum*, *D. Primulinum*, *Epidendrum atro-purpureum roseum*, *E. Ibaguense*, *Lycaste Skinneri* (many varieties), *Masdevallia Veitchii*, *Mesospinidium sanguineum*, *Odontoglossum Bictonense*, *O. Cervantesii roseum*, *O. crispum*, *O. cordatum*, *O. Ehrenbergii*, *O. gloriosum*, *O. Hallii*, *O. luteo-purpureum*, *O. maculatum*, *O. nebulosum*, *O. Pescatorei*, *O. pulchellum majus*, *O. Rossii*, *O. triumphans*, *Oncidium cucullatum*, *O. Kramerianum*, *O. luridum*, *O. Ornithorrhyncum*, *O. sarcodes*, *Phalænopsis amabilis*, *P. grandiflora*, *Trichopilia suavis*, *Vanda tricolor amabilis*, *Warszewiczella velata*.—W. H.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Dendrobium Wardianum.—This is now flowering in many collections near London, and several fine plants of it were exhibited the other day at South Kensington. A specimen of it at Alton Towers is also now bearing twenty-five large richly-tinted flowers. It is one of the finest of all known Dendrobies, and is deservedly a general favourite.

Dracæna congesta.—Of all the varieties of the Dragon tree, this is certainly one of the best for indoor culture. Its habit is extremely graceful, its foliage being borne on an erect slender stem, each leaf gracefully recurved, and of a fresh green colour. Like all other hard-leaved plants, it requires regularly sponging to keep it in good health, and, if the plants are laid on their sides and sprinkled with soft tepid-water, it freshens them up very much. My plants, a nice pair, were purchased in the autumn, and have never ceased growing all through the winter. I bought a plant of *D. terminalis* at the same time, but it seems more delicate and difficult to manage.—H. A., Sydenham.

Clematis indivisa.—I have three plants of this free-blooming species, and consider it to be the best of all for cut-flowers. In habit it is quite distinct from any other *Clematis* with which I am acquainted, having smooth glossy foliage, that contrasts well with its pearly flowers. Each bloom is about the size of a crown piece, composed of about eight white wax-like lance-shaped segments, with a cluster of lilac-tinted anthers in the centre. It is rather too large for button-holes, but for bouquets it is one of the most distinct and beautiful of all winter flowers. I used some of its blooms and buds the other evening in making a wreath for a lady's hair, and it was very much admired. I find Mr. Standish uses it extensively for floral decorations.—J. W. S.

THE FLOWER GARDEN.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Crustaceous Group.

SAXIFRAGA LONGIFOLIA.—I have already alluded (see p. 239) to this as the "Queen of Saxifrages," nor could a more appropriate title be found for this lovely plant; but, before I say more as to wherein those elements of beauty consist that entitle it to that rank, let me ask—what is *S. longifolia*? Some twenty years ago, under the same name, a plant was grown that clearly did not carry out the original distinctive character of this lovely species: its leaves were nearly as broad as *S. Cotyledon*, but devoid of any tendency to an obovate character; it formed rosettes of an equal, if not greater, diameter than this species; its flowers were much fewer and more scattered, and the inflorescence altogether larger. I have myself seen an exceptionally well-developed cyme of the so-called *S. longifolia* acquire the height of 3 feet 2 inches, each petal being dotted with numerous minute crimson spots. These, though in the distance unobservable, added much to the beauty of the individual flowers on a closer investigation. I had long before satisfied my own mind that this was not the true *S. longifolia*, but that it must be referred to Sternberg's variety of the same, to which he gave the name of *S. longifolia* var. *elator*. So different, however, is the plant from the true species, that I was always disposed to look upon it as worthy of sailing under its own name; and I think there need be no

*Saxifraga longifolia* on rock-work.

hesitation in referring it to Kerner's *S. altissima*, recognised as a distinct species by Engler in his "Monograph," under which title I shall presently deal with it. Returning, therefore, to the true *S. longifolia*—for whose introduction into cultivation in this country we are indebted to our indefatigable Alpine-growers, Messrs. Backhouse, of York—we find it, as regards the rosette previous to blooming, distinguished by its narrow linear slightly-spathulate leaves, being much recurved, and nearly convex on the surface, by the presence of a large amount of the calcareous incrustation, and a total absence of offsets from the base of the plant (one form produces these freely; but, as I have not yet seen it in bloom, I can say no more than that it is not the true species). When grown in good well-favoured soil, the rosette will attain a diameter of 9 to 12 inches, composed of considerably over 200 leaves, and, under these circumstances, has a charming effect—so much so as to cause one to wish that it might continue to retain, through a series of years, its juvenile character. When it does bloom, it sends up a dense spike of whitish flowers, whose petals towards the base acquire a crimson tinge from the immense number of minute dots of that colour, the beauty of the tinting being much enhanced by the contrast presented in the yellow-coloured anthers that occupy a varying relationship to the crimson of the petals, according as the stamens retain their normal position, or approximate towards the styles, which they alternately completely surround—a peculiarity, by the way, not confined to this species only, to which I would invite the attention of my readers, at least such of them as may be interested in the singularly complete arrangements by which nature occasionally assists in the process of fertilisation.

As I have before said, the tendency of any plant of this species to throw out offsets indicates at once a divergence from its true typical character; therefore, that mode of increase is not to be depended on. It is, however, to be got true from seed, in a degree, at least, judging from my own experience, of about one in five; the typical plants may readily be selected the second year, and to this somewhat erratic source those who possess the plant must look for increase. The gracefully-curved lines that the leaves present, their exquisitely symmetrical arrangement, accompanied by the well-defined marginal line of white along the sides of each leaf, render this plant, in its true form, fully entitled to the queenly title it has received; and possibly the rich and varied flora of the Pyrenees has never contributed a more charming addition to our rock-gardens than *S. longifolia*, to which mountain range, so far as our present knowledge goes, it appears to be confined.

S. ALTISSIMA, of Kerner, is so closely allied to the preceding species, that it unquestionably claims our attention next. I have already stated that, possessing, as it does, a much taller inflorescence, accompanied by a sparser arrangement of the flowers, it appears to lay claim to a distinct specific title. I believe the plant, which is often seen in cultivation under the name of *S. nepalensis*—a name in the highest degree inappropriate, seeing that we have no record of a crustaceous species occurring in the Himalayas at all—is identical with this species. Its geographical habitat is in the Tyrol; and, if I am not mistaken, it was originally introduced into this country, under the old name of *longifolia*, from the Botanic Gardens at Munich.

S. LINGULATA.—The tongue-leaved Saxifrage is one of the freest-growing border-plants of the large-foliaged section of this group; its rosettes are of considerable size, but lack that symmetrical regularity that characterises the preceding species. The surface of each leaf is slightly channelled, and, being of a greyish colour, the marginal markings do not present the same distinct appearance; nevertheless, as a border or rock plant, it is by no means to be despised. It grows so freely, especially on a cold damp soil, that a small tuft will, in a few years, become a dense irregular patch of nearly a yard in diameter. The flowers are of a creamy-white, quite devoid of any pink colour, and are produced on irregularly-panicled cymes, densely arranged at the termination of the secondary branches. The weight of the bloom usually causes the whole inflorescence to incline to one side, and, after a shower of rain, they are generally prostrate on the ground; nor do they readily assume the perpendicular after having been once bent down. So freely does this plant send out offsets, that, though I have saved large quantities of seeds, I have never deemed it worth the trouble of raising from seed. It is a native of the Alps, Apennines, Pyrenees, and the islands of the Mediterranean, but does not appear to have penetrated into northern Europe at all. According to Engler, *S. lantoscana* and *cochlearis* are looked upon as varieties of this species; but, as I fail to see the relationship, I shall deal with them hereafter as distinct species.

S. HOSTII—said to be synonymous with *S. elatior*, though that which I have cultivated for many years as *S. elatior* is evidently more nearly related to *S. aizoon* than to the species under consideration—is very distinct in its general appearance; its rosettes are comparatively small, not more than 2 or 3 inches across; their leaves are bluntly and broadly linear, recurved at the points, and always of a light yellowish-green colour; the marginal markings assume a distinctly separate and serrated character; it rarely produces flower-stems, and, when it does so, they scarcely ever rise to a height of even 12 inches; the flowers, similar in colour to the last species, form tasselly groups at the ends of the secondary branches. It is a native of the Apennines and the southern slopes of the Alps, but is generally confined to the Dolomitic Mountains.

S. PECTINATA is a compact-growing plant, with leaves about an inch long, gradually tapering from the base to a somewhat acute point. There is, perhaps no species that shows so distinctly those white marginal markings as this; hence, its extreme value as an element recently imported into the flower-garden, and, unquestionably, a line of it has a wonderfully pretty effect, especially in the early spring. When the first push of active vital growth appears, then the frosted silvery character of the leaf-markings comes out to perfection. Its flowers are white, produced in dense compact thyrsoïd cymes,

and rising to a height of about 9 inches. How is it that this plant does not appear to be recognised, even in the subordinate capacity of a variety? In Engler's "Monograph" the very name is completely ignored, and yet, not only has it a perfectly distinct general appearance, but it also retains its character when grown from seed much more perfectly than many of our recognised species. It is a native of Carinthia, extending into Asia Minor, and pretty abundant on the Caucasus.

S. ROSULARIS.—Under this specific title—given to it by Schleicher, a Swiss botanist—a plant has long been cultivated, and so familiar will all my Saxifrage-growing readers be with it, that I feel sure they will agree with me when I hesitate to consider it merely a form of *S. Aizoon*, but look upon it as a good, constant, and most appropriately-named species. Its chief distinctive characters consist in its forming a mass of somewhat lax circular rosettes, varying from 1 to 2 inches in diameter, each rosette formed by a limited number of almost orbicular leaves, whose margins, on close examination, present a set of beautifully-regular cartilaginous serratures, inside of which occur the large crustaceous dots, each being well separated from its adjacent neighbour; the body of each leaf assumes a concave or cup-like character, and is of a deep green. The floral axis rises from 9 to 12 inches high, and its flowers are white, of larger size, and possessing a larger development of disk than occurs in any of the *Aizoon* group. The very fact of its having been cultivated for thirty years, to my knowledge, and that it at the present day retains as perfectly those well-pronounced characters that it did at the first, give it, in my opinion, full and ample claims to the specifically distinct status which I here recognise. It is a native of the Swiss Alps, and grows freely in any dry sandy soil, but, in a damp situation, becomes sickly and loses nearly all its beauty.

PRIMROSES AND POLYANTHUSES.

WITH the wild Primrose all of us are familiar; nevertheless, the true lover of nature, walking abroad in early spring, stoops with delight over a patch of it in full bloom, and not improbably plucks the flowers in admiration of its beauty. But what would he think if, instead of patches of the unpretentious wild Primrose flowers, he suddenly lighted upon a bit of woodland, or some shady glen, the whole of which was carpeted with the richest and loveliest hues—white, yellow, lilac, mauve, red, purple, crimson, and other intermediate shades—all Primroses, and all growing as freely and blooming as abundantly as our old familiar wild kind could possibly do in like circumstances? This conception may be treated as an absurdity. And yet, if Primroses of the most lovely hues of colour, having habits exactly like that of *vulgaris*, and endowed with constitutions as hardy, can be easily and freely grown in our gardens, why may they not be found in abundance in woods and wild gardens? How is the wild Primrose propagated so freely? Of course, chiefly by seed, although, from the grassy nature of the seed-bed, perhaps not one-tenth of all that nature sows germinates. What nature does so imperfectly, and yet so well, surely may be improved upon by the gardener's art; and whilst no one would advise the indiscriminate casting of choice seed in all directions, in the hope that some may grow, it is safe to assert that if holes were here and there scooped out in banks or dells, or beneath the shady trees, and anywhere about the wild garden or woody glades of an estate, and then filled up with fine soil, and just a few seeds of rich-coloured kinds sown, nearly all would grow, and then the transformation would soon be accomplished. There can be no doubt that in the past few years we have made great strides in the production of really good and beautiful forms of the Primrose. The true habit is retained, but the flowers now have a good rounded form, and have substance, and, indeed, possess that refinement of appearance that charms the eye, and, at the same time, satisfies the judgment of a true florist. This is great gain; for, with the recurring desire in the public taste for old favourites, and especially for early spring flowers, it is most pleasing to have these gems to offer as specially adapted to suit the demand that is now arising. One or two kinds have of late been made prominent in the floral world for their diverse, but particular, beauties. These are *Primula altaica*, a

true single primrose, the flowers of which are of a delicate mauve-lilac tint, which is also extremely early to bloom; and *Primula auriculæflora*, a rich crimson single Primrose that blooms most profusely and early, and which has such recognised merits that it has received a first-class certificate from the Royal Horticultural Society. These kinds are in commerce, and are, therefore, obtainable. In the spring of last year a very lovely seedling kind, named *Violet Gem*, also received a first-class certificate, because of its novelty, the rich violet-purple hue of its flowers, and the neat bouquet-like form in which they were borne on the plant. This kind is, however, but the *avant-courier* of many others equally beautiful, and of the same strain, but having great variety of colour, and with most of which the lovers of Primroses will have a better acquaintance as soon as their stocks become abundant. *Fairy Queen* is pure white; *Sulphurea*, large sulphur-yellow; *Magenta Beauty*, a rich tint of magenta colour, and very pleasing; *Rosy Morn*, large, in colour, bright rosy-scarlet; *Lilacina*, delicate mauve-lilac; *Crimson King*, deep rich crimson; *Sunrise*, large rich red; *Queen of Violets*, a charming violet tint in colour, good form, and robust grower; *Marginata*, blooms large, bright red, and edged white; *Glowworm*, deep blood crimson; *Violacea*, very early, distinct, and pleasing; and *Splendour*, large, crimson-scarlet. All of these are quite distinct from each other, and form a lovely selection that few can realise the beauties of till they have seen for themselves. Until they become plentiful they amply repay for pot-culture, and, indeed, when kept under glass during the winter, will bloom early in the new year, whilst their beauties are protected from the rude storms and frost of the open air. With the rising taste for Primroses, of course the double kinds are not forgotten—these being specially favoured, because their flowers are so solid, and are valuable, when gathered, either for button-holes or bouquets, or for that kind of indoor decoration for which all flowers are alike acceptable. With the old *Double White* and the *Lilac*, nearly all persons who have gardens are familiar; they are common and constantly met with, especially in places where spring-flower gardening constitutes a prime feature. They are, also, favourite cottagers' plants, and, in some market and flower-gardens around London are very extensively grown, that the flowers they produce so abundantly in the early spring may be gathered for market sale. In some old gardens huge patches of these kinds are found, the bottoms, probably, not having been moved or divided for many years. As a rule, however, the plants should be lifted and divided every two or three years, as the blooms are then much finer and more freely produced. In order of abundance, the *Double Sulphur* comes next, and it is an exceedingly early kind, and a strong grower. Plants of this sort, if they have done well during the summer, will commence to bloom early in November; and, if kept under glass, will carry flowers all through the winter. Very equal to this, both in habit of growth and early flowering, is the *Crimson Purple*, or, as it is sometimes called, "*The Scotch*." The foliage of both these latter kinds is narrow and tapering, and very smooth. By these peculiarities these sorts are easily distinguishable. The finest yellow is known as the *Giant Yellow*, producing very large double blooms, in colour, straw-yellow, borne upon long stout stems; and it makes a capital variety to gather from for bunching. The richest-coloured, however, is the *Late Yellow*, a distinct kind, more resembling the *White* in habit and size of bloom. Very choice and scarce is the *Rose Double*, a beautiful kind, and one deserving a much wider cultivation; the flowers are in colour rosy-red, of medium size, and freely borne. Then there is the *Purple*, which is a deep-coloured form, and by no means common; and last, though not least, the *Double Crimson*, the richest and most effectively coloured one of the list. This kind is exceedingly rare—so much so that it is difficult to get half-a-dozen plants anywhere, those who have stock clinging to them with great tenacity. As far as my knowledge extends, I believe that these nine kinds constitute the whole of the varieties of double Primroses to be found in cultivation. I have also added to my stock a very pleasing kind called the *Blush*. It is white, shaded with mauve; evidently a sport from the old *White*, and a robust grower. I have examined growers' lists, and can find none others, and but one or two persons offer the whole of them

for sale. This comparative scarcity is due to two causes: careless cultivation and popular negligence. The latter reason, especially, has operated largely to restrict the growth of these Primroses, as of late years the mania for gorgeous summer bedding-plants has acted most disastrously in causing the neglect of many of our hardy border gems. We are gradually creeping out from under the crushing influence of this mania, and there are healthy signs in various directions, that almost forgotten hardy spring plants are once more coming into favour. The Polyanthus forms of the Primrose present many different types, varying from rugged and colourless kinds, scarcely superior to the common Cowslip, to the beautiful gold-laced section, the florists' pet flowers, the markings of which must be as perfect and as evenly defined as it is possible to have them. This is the section of the Polyanthus so popular as exhibition flowers—especially in the north—and named kinds of these are abundant. It is, however, a remarkable feature of this strain, that the very best named kinds of the present day do not present one single feature of advance over the kinds that were popular forty years since. The old florists' rules have "cribbed, cabined, and confined" these show Polyanthuses within such restricted space for improvement, that actually many fine old kinds have been entirely lost, and inferior ones have taken their places. Charming as are a few nice well-bloomed plants of the gold-laced kinds, it is nevertheless particularly noticeable that they all present features of real similarity; so much so, in fact, that it requires the eyes and knowledge of an expert to discover the difference. Still, these have their worshippers, and they are not a few—men who will go into raptures over a laced flower, but will turn with contemptuous indifference from a kind that, however beautiful, is yet without the prescribed pale of show flowers. The richest-coloured, most varied, and finest forms of the Polyanthus are what is now known, for lacking a better name, as the fancy section—these presenting features specially adapted for border decoration, being strong, robust, and standing drought well. Many have blooms as large and rounded as a florin, and, if but admissible as exhibition plants, would soon supersede the laced kinds. Some have very clear and decided colours, and, when in bloom, carry the trusses in dense even bunches, so that they may well become specially useful for spring bedding. The colours range from pure white, sulphur, yellow, mauve, red, purple, and crimson, with many intermediate shades and varied markings, all extremely beautiful. I grew a large mixed bed of these last spring, and think I never saw any mass of spring flowers more attractive and gay than they were, and they only require to be universally known to be as universally admired. There are some particular kinds of the Polyanthus grown specially for market, that differ from any of the before-mentioned sorts, as they have, in some respects, the habit and character of the laced kinds, and are yet devoid of edging, being simply very dark self-flowers with good substance and blooms of medium size; they are peculiar to the London market trade, but present little variety. These are usually sold as roots, large quantities being grown. For

bunching, kinds that have the merit of being dark in colour, and have large trusses on long stems, are most favoured, and any sorts that come well up to these merits are in great request. Of course, any grower for market has need of very large quantities of any one kind, and to obtain these from new ones is a work of great time. The market flower-gardens present many features of interest in the spring, not a few of which are found in the varieties of the Polyanthus. Few plants are more easily grown and increased than the Primrose family, as all the single kinds will seed freely, and reproduce themselves in abundance by that means. Propagation by division of the roots is also simple, the plan being to lift the plants about November, and carefully pull or cut the roots into several parts, and then replant again in good well-dug soil; these young plants will carry good heads of bloom the next spring, and should be allowed to remain untouched for two years at least. The

greatest enemy of the Primrose is drought; it likes a little shade, but specially delights in a nice cool deeply-worked soil, into which it can send its roots freely. A dressing of old pot earth around the stools during the summer, especially after a soaking rain, is most serviceable, and adds not a little to the growth of the summer crowns. When these are strong, autumn blooms will always follow, and thus the flowering period is prolonged. Choice new or scarce kinds are best kept in pots for a year or two until their stocks are increased, when they may be planted out at discretion. A. D.

Lilium speciosum.

JAPAN LILIES.

Among the species of Lilies, introduced into this country from Japan, the varieties of the lance-leaved kinds are most valuable summer-blooming plants, either for conservatory decoration or for beds and shrubbery borders in sheltered positions. Bulbs of this class are now cheap, and easily procured, while their culture is so easy that failure need scarcely be apprehended. For conservatory or balcony culture they are best grown in pots, and, as they are gross feeders, a rich compost should be used for them, such as fresh fibrous loam and leaf-mould, with a sufficient quantity of coarse sandstone-grit in it, to keep the whole in a porous condition; and, after the pots have become filled with roots, repeated doses of clear liquid-

manure will be found to be beneficial. By clear liquid-manure I mean that from which all coarse sediment has been removed. Unless this is done, this sediment forms a close layer on the surface of the compost, clogging it up, and preventing the circulation of air, which is so essential to the roots of all plants in active growth. In potting Lilies I use 12-inch pots, place three bulbs in each on a well-drained bottom, and make it a rule to plant the bulbs low down in the pot, so that, when they are covered with an inch or two of compost, the pot is little more than half-full of soil. Thus, when the roots appear above the soil, fresh material is easily applied to them, which infuses fresh vigour into the young growths, and, as a matter of course, finer blooms are the result. As soon as all danger from late spring frosts is over, I take the Lilies from the pits or greenhouse, and plunge them in coal-ashes outside, in a sheltered situation, at the

manure will be found to be beneficial. By clear liquid-manure I mean that from which all coarse sediment has been removed. Unless this is done, this sediment forms a close layer on the surface of the compost, clogging it up, and preventing the circulation of air, which is so essential to the roots of all plants in active growth. In potting Lilies I use 12-inch pots, place three bulbs in each on a well-drained bottom, and make it a rule to plant the bulbs low down in the pot, so that, when they are covered with an inch or two of compost, the pot is little more than half-full of soil. Thus, when the roots appear above the soil, fresh material is easily applied to them, which infuses fresh vigour into the young growths, and, as a matter of course, finer blooms are the result. As soon as all danger from late spring frosts is over, I take the Lilies from the pits or greenhouse, and plunge them in coal-ashes outside, in a sheltered situation, at the

same time giving them the protection of a tiffany awning, which not only breaks the force of the sun's rays, but also shelters the young growths from high winds. A border under a north wall suits them admirably, as I find that they do not like the full glare of the summer's sun. Grown in this way, I have had fine specimens, from 4 to 5 feet high, and nearly as much through, bearing from 100 to 200 fully-expanded flowers and buds. When in this state of perfection, they are invaluable for indoor decoration, and are also useful for conservatory ornamentation or exhibition purposes.

Out-door Culture.

Lilies of this class will also succeed in beds and borders for several seasons. For this purpose I start the smallest bulbs two or three in a 32-sized pot at the same time as those for pot-culture, viz., in February or March; but, instead of potting them on like the others, I simply turn them out of the pots into the positions which they are to occupy about the beginning of June, after which they require no attention, except staking, and occasional waterings in dry weather. A great point in the way of securing success is to plant deep in the following manner. First, take out the soil of the bed 18 inches deep, forming a hole about the same width. "Imagine a hole half-a-yard deep in which to plant a Lily"—it may be said; but this is my system, and I must be blamed, after having tried it and failed to experience its advantages over sticking in the bulbs to be half-roasted by the scorching sun, if success is not the result. In some cases I have taken out a hole 2 feet deep, but the depth above mentioned is generally sufficient. At the bottom of this hole I place 3 or 4 inches of broken bricks, or lime-rubbish, to act as drainage, or some rough littery manure from the stable-yard does nearly as well, and upon this I place about 4 inches of a rich soil, composed of ordinary garden loam and well-rotted hot-bed manure in equal proportions, and on this I turn out the Lilies, as above stated, in June. The ball need not be broken, and fill up round the sides with the loam and manure, giving a good watering to settle them in their places. Only just cover the ball. Now, it will be seen, that each plant is in a little well, or hollow, the sides of which serve to protect it from rough winds until the roots are firmly established in their new quarters. As the plants increase in height, fill up the hollow with rich sandy earth, and water as required. It will thus be seen, that when the hollows are filled level with the surface of the bed or border, the roots are at least a foot below the surface of the soil, and, no matter how hot and dry the season may be, Lilies thus planted will have plenty of moisture below in which their roots will luxuriate in spite of the hot burning crust of dry earth which surrounds the stems above. Our out-door Lilies, thus managed, have invariably been greatly admired.

I will now give a short list of the varieties which I cultivate in the manner just described, and, may remark, that on warm dry soils in some favoured localities, the bulbs need not be taken up in the autumn, as they are hardy enough to withstand the most severe winter, if mulched with a thick coat of stable dung or leaves, covering the whole with a thin layer of soil to prevent its having an untidy appearance.

L. SPECIOSUM.—This is a showy form, having reflexed, wax-like, pure white segments suffused and spotted with crimson. The brightly-coloured anthers also add to the beauty of the flower; but if they are cut off before the pollen-cells burst, the flowers keep much longer in good condition than they do if left undisturbed.

L. SPECIOSUM ALBUM.—This is like the preceding in all respects, except that the flower is of the purest white, and, if anything, rather smaller in size. It is distinct, and well deserves cultivation as a variety.

L. SPECIOSUM PUNCTATUM.—This is as nearly as possible intermediate between the above, the segments being of pearly-whiteness, delicately suffused with soft flesh-colour, with a few deeper-coloured rosy spots.

L. AURATUM.—This, "the Golden-rayed Lily of Japan," as it is called, grows well and blooms profusely, treated as has just been described. It is generally grown as a pot or house-plant, but it is very nearly hardy—quite so in positions as far

north as Leeds, and when this fact becomes fully recognised, it will prove to be one of the best, most easily-grown, and showy of hardy bulbs. Seedlings vary much in the size and colour of their flowers, but all are beautiful. This variety can now be had very cheap, bulbs being imported from Japan every autumn and winter by the thousand.

Many other kinds of Lilies also, may be grown as has just been recommended, and will amply repay the little extra trouble which they receive. J. B.

Hardiness of Eryngium bromeliæfolium and Pelargonium Endlicherianum.—Mr. Perry notes the complete hardiness of *Eryngium bromeliæfolium* (p. 241), and Mr. Harpur Crewe notes the non-hardiness of *Pelargonium Endlicherianum*. Here the case is exactly the contrary; the *Pelargonium* seems quite uninjured by the winter, while I have never been able to keep *Eryngium bromeliæfolium*. The first frost kills it, while the very similar *E. yuccæfolium* survives. This leads me to remark that the term "hardiness" is very misleading. A plant dies during the winter, and it is at once pronounced not to be hardy; but this is certainly not proved; it may not even be true of that particular garden, and it may be quite untrue of a garden not a quarter of a mile distant. Plants die from many other causes than cold; from weakness, old age, slugs, mice, carelessness, or unsuitable soil. Plants, again, are often pronounced not hardy simply because the owner has no patience. Very many plants, after flowering or after transplanting, rest completely for a year or even more; the owner pronounces them dead and they are dug up and thrown away. In this winter I shall lose a great many plants of whose hardiness there is no doubt, yet which have certainly been killed by the winter. They have not been killed by the cold but partly by the wet, and partly by the alternation of mild with frequent, though not severe, frosts. The plants that have suffered are chiefly herbaceous plants, which do not die down beneath the surface, but which show an exposed growth of green.—H. N. ELLACOMBE, *Bitton Vicarage*.

Winter Cress (*Barbarea vulgaris variegata*).—This is one of the hardiest of decorative plants, and one which is exceedingly useful for spring bedding, for which purpose it should be sown in August. If sown a month or six weeks earlier, however, the young plants have a pretty appearance throughout the winter months. The plants from these sowings should be cleared away the following summer, and something else substituted, as their liability to run to seed makes them objectionable. If sown now, they will prove useful in the flower-garden in summer. They grow freely, and the leaves are beautifully variegated with yellow, which is quite permanent. They are well adapted for edgings to flower-beds and borders, and they enjoy a moderately damp and rich soil. Self-sown seeds come up freely where plants that have been allowed to seed have been growing.—W. FALCONER.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

A fine Rose Hedge.—In Lord Middleton's garden at Applecross is one of the finest Rose hedges in the kingdom, which, last season, was one sheet of flowers. The variety is *Gloire de Dijon*, and the hedge is used as a screen, which simply consists of a neat wire fence with five strands, to which the plants are fastened. This hedge is 5 feet in height, and over 200 feet in length.

Lonicera Standishii.—For several years we have noticed this sweetly-perfumed white-flowered Honeysuckle blooming in front of the Museum at Kew. It is not showy, but its foliage looks fresh and green during the summer months, and its grateful odour and habit of flowering early, entitle it to a place in every garden.

The Early Bulbous Iris.—One of the most singularly beautiful of spring flowers, is the early bulbous *Iris* (*I. reticulata*), which is now flowering freely in several establishments in the neighbourhood of London. Its flowers are of a violet-purple, veined and beautifully stained with orange, and deliciously fragrant. In well-drained sandy soils this plant is thoroughly hardy, and on account of its early flowering deserves a place in every garden.

Night-flowering Plants.—You must add to the list of these (p. 241) the *Yuccas*. They rank in this respect with the Evening Primrose. The flowers begin to expand at dusk—they fully expand during the night, and though seen fully expanded during the day following, they are then beginning to close. It is partly owing to this arrangement that the flowers are so seldom fertilised in Europe. Those of your readers who wish to know more of this subject should consult Dr. Engelmann's interesting paper on the Genus *Yucca*, in the "Transactions of the Academy of Science of S. Louis," April, 1873.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

Origin of Double-flowered Pelargoniums.—The following extract from the journal of a horticultural tour through some parts of Flanders, Holland, and the north of France, in the autumn of 1817, by a deputation of the Caledonian Horticultural Society, may be interesting to M. Sisley, as it appears to be what he has been looking for in vain in the very town where the plant was common at about the time he mentions:—"We may here notice that an ornamental variety of *Pelargonium inquinans*, with double flowers, is very common at Ghent, no fewer than ten different competitors having exhibited flowering specimens of it at the last festival. This variety, we believe, has not yet reached Scotland."—J. G. NELSON.

GARDEN DESTROYERS.

GARDEN PESTS.

By THOMAS BAINES, Southgate.

Woodlice.

THESE are exceedingly troublesome when they exist in large quantities. Being almost omnivorous, nothing comes wrong for them. They seem to equally enjoy a juicy Peach or Melon, a nice fresh Mushroom, the roots of an Orchid, or the most putrid animal or vegetable matter, if in a sufficiently dry state. Where they exist in large numbers in the Orchid-house, they do great damage by eating the young feeding points of the roots, especially of such things as Cattleyas, that require to be kept dry when not in active growth, but which, nevertheless, make a good deal of roots during that season. If the woodlice are numerous at this time, they will destroy almost every root that is made on the surface of the pots, rendering the growth which follows small and weak. They are extremely partial to horse-droppings in a half-dry state; where they exist in quantities, a number of 10-inch or 12-inch pots may be kept, filled with droppings, and placed amongst the plants, near the pipes, or wherever they congregate. If these are taken out and emptied once a week, the insects destroyed, and more droppings put in, they may be soon reduced in number, so as to be incapable of much harm. Sweet Apples or Potatoes, scooped hollow and placed upon the pots will attract them; if these are looked over every day, considerable numbers of the insects will be found underneath. Melon-frames and pits are their favourite haunts, especially the latter, if the brick-work is out of order, affording them means to secrete themselves. In the winter, whilst the pits are empty, point up all defects in the mortar, lime-wash, and remove all old soil or other material in which they can find shelter; and, as soon as the young plants are started, commence placing traps for them at once—do not wait until they exist in large numbers. It is the delay in taking means for their destruction until the place is swarming with them that renders them capable of so much mischief. Nothing is better than boiled Potatoes cut in two, the pieces put simply in small flower-pots, and over these a little dry Moss. If the traps are examined once a day, the insects will be prevented from ever existing in sufficient numbers to do harm. In the Mushroom-house they are a very great nuisance, for here everything exists congenial to their taste—warmth, food, and material in which to lodge. If they exist in great numbers, boiling water poured down the sides of the beds up to the wall will destroy all it comes in contact with. The little pots with the Potato baits can be used with advantage; but here, as with the Melons, taking time by the forelock in destroying them, before they exist in numbers sufficient to do much harm, is the right way. They sometimes are a source of annoyance on the Peach-wall, by eating holes in the ripe fruit; it is not the quantity they eat, but the number of fruit they disfigure. Here they exist where the mortar in the joints is defective, and more especially under the coping, where they meet with suitable lodgings. The best remedy is keeping the walls well pointed, so as not to allow them any place to secrete themselves; without this they cannot exist, for all the soft-billed birds, such as robins and hedge-sparrows, devour them eagerly if they can get at them.

Wireworms.

These are the worst of all the earth worms, their ravages on the corn crops of the country in some seasons being such as to affect the price of the staff of life, and frequently necessitating the ploughing up of large breadths of corn through the destruction of the plant. In gardens they are equally destructive, especially in such as are newly-made, or where there has been new soil added from Grass-land. The wireworm is not at all fastidious as to any particular description of food, being equally at home feeding on the roots of a choice Ranunculus, Pink, or Carnation, or in the kitchen garden on the more homely fare of Potatoes or Beet. In some parts it exists in much greater numbers than in others. In the south of the kingdom it is much more plentiful than in the north. There is nothing that suffers more from its attacks than that now much and undeservedly-neglected flower, the Ranunculus.

Its equally beautiful companion, the Anemone, suffers by the attacks of this insect in a somewhat less degree. The old Ranunculus grower finds it necessary to pass through the hand the whole of the new soil he yearly adds to his beds, breaking every piece that is sufficiently large to conceal any of these unwelcome visitors; and, after the soil is consigned to the beds, it is necessary to resort to the further precaution of inserting slices of Potatoes thickly an inch below the surface of the soil, looking over them every day. When any addition of new loam has been made to Pink, Carnation, or Pansy beds, the placing of these Potato traps is necessary, or the mortification most likely will have to be endured of seeing many a fine pair of plants destroyed. In newly-made kitchen gardens for two or three years they are very troublesome. I have seen them attack the crops of early-sown Peas, especially when the season is such as to delay their coming up for a considerable time, eating three-fourths of the seed by the time the plants had made their appearance above ground, and were, consequently, in a great measure dependent upon the seed for support. Potatoes they completely destroy the quality of; if a tuber is pierced even to only the depth of a quarter of an inch by wireworm, the texture of the Potato is spoiled, being, when cooked, devoid of the dry sparkling starch, and more like a piece of soap. French Beans, Runners, and Broad Beans also suffer from their attacks. They frequently are very destructive to the different members of the Cabbage family, often being mistaken for the ordinary Cabbage grub or clubbing. I have found with this, as with other garden pests, that in some parts of the country it is more partial to one particular crop than in others. The most effectual means I have ever tried on new broken-up land was, at the beginning of March, to sow the whole over with a thin crop of Mustard, letting it grow until it was just coming into flower, and then digging it under, just covering it with the soil. It would appear that the plant so treated has the effect of killing the wireworms which feed upon it. Objection may be taken to the loss of time which this measure necessitates; but it frequently happens that the ravages of the insect are such as to render it impossible to obtain any crop until something is done to destroy them. Rape-cake crushed fine, and sown on the surface of the ground, which they devour, will kill them. The time occupied from the eggs being deposited in the earth until the insect assumes the winged state and takes flight, is much longer than with the generality of insects nearly allied, and during such times its depredations extend.

American Blight.

This insect, which is most destructive to Apple trees, breeds fast, and spreads with great rapidity. In the garden or orchard, where it makes its appearance on a single tree, if left unmolested it will soon be found in quantity on the surrounding trees, even at a considerable distance. It establishes itself in any crack or inequality in the bark, and breeds in quantity, giving the trees for a portion of the year the appearance of being partially coated with cotton-wool. Like most other insects that attack the bark of plants, the injury it effects is not so soon apparent as in the case of such insects as confine their depredations almost exclusively to the leaves. It causes unsightly protuberances on the bark, and ultimately reduces the trees which it attacks to a stunted unhealthy condition. It is difficult to completely eradicate it, its destruction being well-nigh impossible, where it once gets established in large orchards. The amount of labour it would require to eradicate it when it attacks large trees, would preclude the possibility of attempting the experiment; but in moderate-sized gardens, where the trees are small, it can be destroyed, especially if there is no delay in taking means for its destruction as soon as its presence is discovered. Some years ago it made its appearance on half-a-dozen trained Apple trees at one corner of the garden. One of these was of an inferior kind, consequently I determined to experiment upon it. First, I procured from the gasworks some ammoniacal liquid; one-half of the tree I painted over with the liquor, full-strength, the other half with it diluted with water to the extent of one-half. The application was made as soon as the leaves had fallen in autumn. The destruction of the insects was complete, as also the tree on the side dressed with the liquor in its undiluted state: the

other side painted over with the liquor diluted was not injured in the least; nevertheless, I would advise anyone using this remedy, not to use the liquor in a stronger state than from one-third to two-thirds water, for, although on several subsequent occasions, I used it at the strength of half-water with the most effectual results without injury to the trees, yet I believe the liquor obtainable in some places is much stronger than in others. It should be applied as soon as the trees are out of leaf in the autumn, as if delayed further in the winter, the buds begin to swell, endangering their falling-off. I have tried washing the trees over with a mixture of lime-wash, and lime and soot combined; of Gishurst and soft-soap; but none of these were of much avail, the insect soon re-appearing afterwards, and necessitating a continued repetition of the remedies which had been employed.

Lilies Injured by Insects.—My gardener has not been able to succeed satisfactorily in the culture of Lilies and other bulbs grown in the hot-houses and greenhouses for the last year or two. In turning out pots of *Eucharis amazonica* and *Vallota* the other day, he observed on the bulbs and on the roots what appeared at first to be minute grains of silver-sand; but, on observation through a pocket lens, he discovered that these apparent grains of sand were small insects, with transparent bodies, and brown legs and heads, of more than one variety, some with round bodies, and others with long bodies of various lengths. Further investigation showed that the roots of some of the sickly bulbs had been perforated by these insects, which had also eaten holes in the body of the bulbs themselves, and are to be found, even when the bulbs are not eaten, between each layer of scales. In his somewhat lengthened experience of insect enemies, my gardener had never met with this sort of foe before, and is in ignorance how to get rid of it. I have sent you portions of the *Eucharis* and *Vallota* bulbs, on which the insects abound. Will you be so good as to inform me what insect it is which has destroyed our Lilies, and what we ought to do to get rid of it? The bulbs have been shaken out and powdered with lime as an experiment; but sufficient time has not elapsed to prove whether this mode of treatment will succeed or not.—W. P. S. [The insect is one of the snake-millipeds, named *Julus punctatus* by Fabricius, and *Julus pulchellus* by Leach. It is both carnivorous and herbivorous, and is often very destructive to the garden. My belief is, that they are general feeders or scavengers, and that they are often introduced into pots and beds along with insufficiently-decayed manure. Once introduced, however, it is most difficult to get rid of them. Curtis recommended what your correspondent has thought of—the application of lime. He says, “Whether lime would answer the purpose I have no means of ascertaining, but I am inclined to think it might; for, I believe, they cannot endure heat, and I am certain they are not able to exist without humidity, for, if confined in a box deprived of moist earth or damp Moss, they die in a few hours.” Unhappily, they will live as long as the root or bulb they are attacking. The specimens sent along with some fragments of bulbs, in a wooden box, are fresh and lively, although, after two days drying in the box, the portions of bulb cannot be said to be so. Among the remedies suggested are watering the soil with lime-water, spreading soot on it, sprinkling nitrate of soda round the plants; applying salt, and enticing the insects away by traps of slices of Potatoes, Cabbage leaves, &c., to be afterwards examined, and the insects destroyed. Among the Millipedes there are also small Acari, which will, doubtless, succumb to the same treatment. Your correspondent will confer a favour upon many if he will communicate the result of his experiments to you, whether they prove successful or failures.—A. M.]

Penalties for Destroying Small Birds.—Having seen in THE GARDEN a correspondence relative to the destruction of birds in gardens by way of protecting Peas and other crops, I beg to remind your readers that, by the 35th and 36th V., c. 78, anyone destroying any of the birds therein mentioned, from 15th March to 1st August in every year, is liable to a very heavy penalty. I would, therefore, strongly recommend that no traps be set, as it is not possible at all times to catch the right bird, and, in case of the wrong bird being killed, the penalty is incurred.—J.

Apple-tree Aphides.—What is the black incrustation on the accompanying Apple shoots? I suppose it to be an embryo form of some aphid, but do not remember to have met with it before.—E. D. [The incrustation in question consists of the eggs of *Aphis mali*.—A. M.]

Cure for Greenfly.—Greenfly, especially on Roses, may be kept under by using the following mixture:—Dissolve 8 lbs. of the best soft-soap in 12 gallons of warm rain-water; then, when the water is cold, add a gallon of strong tobacco-juice. The use of sulphur and daily syringing with soft-water is the best cure for red spider on plants or fruit-trees, where the soap mixture cannot be used.—W. T.

A HOLIDAY TOUR.

By THE EDITOR.

FERRIERES.

It has long been a fashion with continental lovers of gardening to employ Englishmen to form their gardens, and, among those so formed, there is none more remarkable than Paxton's work at Ferrières, the princely seat of Baron Rothschild, and none which will better repay a visit from the traveller traversing the dreary fields of this part of France. The house, as well as the grounds, and almost everything about the place, was the work of Englishmen, and the gardens show an instructive mixture of the best features of the horticulture of both countries. As a garden, or any part of it, is only really worth describing, in so far as it is instructive or suggestive to those for whom it is written, we will only allude to those features that possess some interest for the English reader. It is at once distinguished from nearly all French château gardens by having Grapes, and other indoor fruits and hot-house plants, generally quite as well-grown as in the best English gardens. The design of the grounds, too, is far above the average degree of merit, though the fairly well-formed sheet of water is somewhat too near the mansion, which, as our illustration shows, is a very large one. An unhappy feature, and one which cannot be denounced too much, is a formal margin of stones around it, somewhat similar to, but smaller than, that which now disfigures a part of the ornamental water in the Regent's Park. The individual, who causes a neat little barricade of stone to be built around a piece of ornamental water may have genius, but it certainly is not for landscape-gardening. The very line of beauty, so to say, where the turf might slope easily down to kiss the water, or the wavelet play amongst a fringe of Forget-me-nots or Arrow-heads, to be finished off like a manure-tank! It is too bad. The line of kerb-stones, placed along the margin of the Serpentine, is another “improvement” of the same type, and a little worse, because even more formal. It is an instance of money thrown away to produce a needless eye-sore. As a protection to the edge from the action of the water such things are never of any real use, and, in the case of the Serpentine, the water is frequently below the kerb-stones. The best margins for artificial water are sand or turf, and, if these are disturbed by the action of the water, they will certainly be more fitting in their worst condition than cement, bricks, flints, or kerb-stones. The house is, of course, fortified with a terrace-garden, but this is not over extensive or overdone with bedding-out. On its steps, one day, Jules Favre met Bismarck, when he went to plead in vain the cause of beaten France. The king and Bismarck had their quarters here when the Germans overran the plains around, and gave orders that not a finger was to be laid on anything. Had it been otherwise, the specimen *Wellingtonias* might have proved useful under the soldier's pot, or suffered some equally ignoble fate, as did many thousands of specimen trees around Paris during the siege. Probably the finest Orangery in any private garden in France is here, and the Orangery system of cultivating plants is here seen in its best aspect. Nothing can exceed the health and beauty of the specimens grown in enormous, but well-designed, tubs, and standing so close together that the dense heads touch, and one seems in an Orange grove. In addition to the many Orange trees, there are superb pyramidal Myrtles, nearly 20 feet high, in tubs; numbers of tubs of the New Zealand Flax and large specimens of the Australasian *Araucarias*, which do well treated thus. The Orangery system, well carried out, is perfect protection during winter; but there is no growth at all till the plants are placed in the open air in May, or whenever their various degrees of hardiness will admit of it. The darkened roof and back-wall, and the absence of all heat beyond that afforded by the walls, secure these ends. In English gardens, the Orangery system is of little or no consequence; it may have been otherwise when we had few or no evergreens but those preserved by its aid; now-a-days, we have so many that few gardens do justice to the half of them. The troublesome and expensive system of tubbing and moving the plants in and out of these structures is also highly against the system, particularly as the plants possess no peculiarity of form and colour that are not afforded better by hardy subjects requiring

VIEW IN BARON ROTHSCHILD'S GARDENS AT FERRIERES (SEINE ET MARNE).

none of these costly attentions. The system of planting-out Palms and many other fine-foliaged plants in a large house, and with an eye to picturesque effect, is here well carried out, and the effect very good at all seasons. The fresh green *Lycopodium denticulatum* forms, as usual, the turf of the small but beautiful landscape. In addition to the many Palms and other plants recommended for this purpose, *Theophrasta imperialis* may be named. Specimens here planted out exceed any seen at our exhibitions, and are tall imposing columns of noble leaves. Among trees, good specimens of the Weeping *Sophora* are employed with fine effect near the water at Ferrières. Perhaps its slow growth with us prevents it from being more frequently seen in our gardens. A large extent of the pleasure-grounds at Ferrières, very well planted and designed in all its parts, is devoted to extensive, well-built, and richly-stored aviaries, menageries, &c.; but, as these are somewhat out of our province, we will step into the

Hardy Fruit Garden.

This is the finest we have seen in any private place in France; and, though certain kinds of fruit may be grown better in places specially devoted to their culture, on the whole, this is as good a garden for hardy fruits as we have seen in France. The first thing that strikes the eye are the splendidly-formed espaliers. They are more than twice as high as those usually seen in our gardens, being about 10 feet high; but not a square foot of the whole surface of a trellis several hundred feet long is without the portion of branch which the fruit-grower originally intended it to carry. The form mostly employed is the *Palmette Verrier*, of which an illustration will be found in page 271; and, of this, there are scores of specimens as regularly formed as if the shoots pushed and sap flowed at the bidding of the gardener. Walks, running the length and breadth of the garden, are planted regularly with these high trellises, the effect of which is very striking. Other kinds of espalier trees, of which the branches do not turn up at the ends, but run obliquely their whole length, are abundant here, and are preferred to the *Palmette Verrier*, which, once formed, does not admit of increase in size. Trellises for espalier trees are very much more common than with us. The reason is that the autumnal winds are very destructive to large finely-grown Pears on pyramidal trees; on trees fixed to espaliers the fruit does not tumble off before the strongest September gale. This is, indeed, an important consideration, for those who are thinking of growing the finest kinds of keeping Pears. This garden contains hundreds of the finest pyramidal Pear trees I have ever seen, tall, stoutly and regularly set with branches, each, in its turn, furnished, from top to bottom, with plump fruit-buds. Each is a picture in itself in the eyes of a lover of fruit culture. Yet, beautiful as they are, there remains the objection that fruit grown in this way and carefully looked after, in all respects, is liable to be dashed to the ground by an autumnal wind; and, hence, the grower cannot depend on them as on an espalier. Cordons of the various fruit trees, mostly simple cordons, are employed, when the aim is to cover the wall quickly and get an early return. Ground cordons of the Apple form a continuous and frequently inter-grafted line by the side of the walls, and are very useful in the production of fine specimen fruit of the more esteemed kinds. There is a deep, a too deep, permanent coping to the walls, and, beneath, iron stays to support a temporary coping, not less than 2 feet wide during the blooming season. This, as a rule, will not be applied till the trees are in flower next month. It is particularly to be observed that good growers of the finer winter Pears, in this country of fine Pears, insist on the necessity of having a wide coping over the Easter *Beurré*, not only when in flower, but throughout the season. They hold that, in a climate so changeable, and frequently so severe, spotting, cracking, and various other maladies, are best guarded against by a deep coping. Happy the Virginians and Californians, who, in their generous and never capricious climate, grow the finest Pears in the world!

It is impossible to give the reader a fuller idea of the contents of this garden, except by the aid of elaborate engravings, which it would take long to prepare. All who are much interested in fruit culture should take an opportunity of seeing it when the trees are in bloom, or in fruit; and, if a

little late in the fruiting season, the richly-filled fruit-room will show that the garden is as remarkable for the quality and abundance of its fruit as for the perfect training and general good health of the trees.

THE KITCHEN GARDEN.

FORCING VEGETABLES.

Rhubarb.

RHUBARB may be forced in an early Peach-house, in a Vinery, under pots or boxes, and, in all cases, successfully, but I find the following simple method best, inasmuch as it produces plants which are more easily gathered, and superior in quality to those produced by any of the methods just named. About 3 feet of the soil in which the crowns are growing are left as a bed, on each side of which a trench 2 feet deep and 2 feet wide is dug out, and filled with half-decomposed horse-dung firmly compressed. When this is done, in order to form a span-roof, three, four, or six equilateral triangles are put over the bed, the bases of which are supported on bricks, or are driven into the ground on the outer edges of the bed, and held together at convenient distances by means of a beam or plank run along their tops. Short narrow boards are then laid (about 3 or 4 inches apart), sloping from the outer edges of the ridge to the top beam, and, finally, the whole is covered with a sufficient quantity of dung or leaves to raise a good heat. A few 4-inch drain pipes passing through the dung serve as ventilators, and are useful. As the stems become rather drawn when the temperature exceeds 60°, one end may be built up with litter, the other used as a door, and a truss of straw will be most suitable for that purpose, provided it is sufficiently large to fill the aperture. The dung may be turned, and supplemented with more to keep up the temperature, but such is seldom necessary.

Seakale.

The treatment which suits Rhubarb also answers well for Seakale, only, for the latter, less heat is necessary than for Rhubarb. A temperature of 50° is sufficient for Seakale, or even less, if it is kept close. Seakale forces well in a Melon or Cucumber bed, with a little soil in the bottom for the roots to grow in, and about a foot of space for head-room. The soil and roots, when planted, should receive a good watering; then, fill up the space mentioned with leaves, free from slugs or woodlice, and on the leaves set French Beans or other plants. This plan is no better than forcing in the open ground, under boxes or pots covered with litter; but, being always to be depended upon, a first crop can be obtained very early in this way. We force Seakale successfully here on ridges 2 feet high, by 2 feet in width. The ridge, which is forced one year, rests the next; and is again forced the following year. The crowns are set 2 feet apart. On the decayed leaves being cleared away, the ground is slightly forked; a liberal dressing of salt and finely-sifted coal-ashes is spread on the surface; and these help to keep the slugs at bay. Over each crown is placed a box, corresponding in size to the crown. The sides of the bed are then built up with 2 feet in thickness of heating material, and over the boxes about a foot of the same is spread. Three weeks later, excellent Seakale may be gathered; the boxes are then shifted to fresh crowns, and the same operation is repeated. A succession is easily obtained, but, of course, the quantity forced is in proportion to the consumption. Should more come in than is required, it will keep for weeks, by setting the bases of the heads in platters of water, in a cool cellar.

Asparagus.

Nothing gives greater satisfaction than a good dish of Asparagus in mid-winter, and this may be easily obtained. Crowns three years old and upwards are best adapted for forcing. A close frame, 4 feet deep, is filled close to the glass with brisk fermenting dung, firmly trodden, and this receives a good watering; after which, inverted turves are laid over the surface, the lights put on, and the whole allowed a few days to settle, and for the heat to rise. A three-year-old Asparagus-bed is then selected, and beginning at one end the crowns are carefully lifted with a fork, at two, three, or four

different times, as they may be required. In re-planting, they are placed as thick as they can lie on the turves, which, by this time, will have acquired a very genial heat; and they are covered over with sufficient coal-ashes to conceal the roots; coal-ashes I find to be better for the purpose than soil, as slugs are not so liable to harbour in them. It is better to lift a whole bed than a crown here and there, as the bed can be prepared again and sown afresh. After going over all the plantation, taking one or more beds in a season, according to circumstances, the first bed will again be ready for forcing, provided the Asparagus ground is large enough to furnish one or two beds every four or five years. The frame should be kept rather close (if the steam is not too great) until the buds appear; after which, air may be freely given at the back, especially if green Asparagus is required, but if blanched heads are wanted, little air and no light are necessary; and the quicker they are got up the more juicy and crisp they will be found to be. When the crowns become exhausted, they may be thrown away, to give place to others, as they are of little or no use afterwards. As the dung will have sunk a foot or 18 inches in the beds, the deficiency may be made up with fresh material; but, for a third batch, the frame should be cleared out altogether.

Potatoes.

Potatoes seldom repay the trouble of forcing them. It is a common practice to force them in pots in an early Vinery; but I have always seen them attain a much greater degree of perfection in a dung-frame than in pots. A moveable three-light frame, placed over a pit dug in the ground to suit it, answers well. It should be from 3 to 4 feet deep, and filled with fermenting dung, over which should be spread about 6 inches of soil. When the latter has become sufficiently hot, the tubers may be planted in it 6 inches asunder, in lines 12 inches apart. Should the tops grow faster than the dung subsides, the frame may be raised about a brick in depth at a time. Linings must be attended to, and protecting material should be at hand in case of frost. Tepid water should be given if the soil gets too dry; but one good watering is generally sufficient in the winter months. For pot culture, Potatoes are best planted in 4-inch pots, in which they should become rather pot-bound; then shift them into 10-inch pots, in which they will ripen.

French Beans.

These may be forced in pots and boxes, or they may be planted on Vine-borders or Melon-beds; the principal points, as regards success, being heat and proximity to the glass. Red spider is a troublesome enemy to French Beans, and should be checked, on its first appearance, by consigning all affected plants to the rubbish-heap. Six-inch pots are the best in which to grow them. One piece of crock should be put in the pot, and over that a handful of half-inch bones, which serves for drainage as well as for manure. The pots are then half-filled with good yellow loam, and five seeds are planted in each pot. They are then placed near the glass, in a dung-frame or forcing-pit, in a temperature of from 65° to 70°. They are then watered freely, and the points are stopped at the third bud. When the flowers begin to appear, the pot is filled up (leaving plenty of room for water) with equal proportions of loam and old Mushroom-manure. This is of more service to them, at this stage of their growth, than filling it up at first. The bones over the crock are also a great stimulus to them; for, on turning out the ball, they will be found surrounded by roots. Staking must be attended to; and, for this purpose, nothing answers better than pieces from a worn-out Birch-broom. After the flowers have set, manure-water will be found very beneficial to them. When grown on an inside Vine-border, it is best to start them in large 60-sized pots, and to plant them out in drills, running from back to front, a foot apart. In the case of a Melon or Cucumber bed, one line on a raised ridge in the centre does well; but I prefer pot-culture, inasmuch as they are easily shifted from place to place; for instance, when set, they can be moved to a shelf at the back to make room for others.

Parsley.

It is seldom necessary to force this, but in the case of an emergency it may be done successfully. Lift good strong roots, cut off the under part about 2 or 3 inches from the top,

pot them in 4-inch pots, and place them near the glass, in a temperature from 60° to 70°, keep them rather moist, and, in a fortnight from the time of introduction into heat, excellent Parsley may be gathered. A stock of Parsley may be kept up all winter by planting a dry cold frame with good strong roots in the month of October.

Carrots and Radishes.

A gentle hot-bed close to the glass is best suited for these. About 4 inches of rather light soil should be spread over the dung, on which the seeds should be sown broadcast. They should then be lightly covered and watered with a fine rose. Thin them to the required distance apart when large enough to handle, and protect them with mats during frosty nights.

Wotton Gardens, Aylesbury, Bucks.

JAMES MORRISON.

THE GLOBE ARTICHOKE.

In most establishments this Artichoke is highly esteemed; and it is important that every cultural arrangement that will tend to extend the season of bearing should receive due attention. Years ago it was the custom in most gardens at the approach of winter to cover the plants entirely, or nearly, with litter, and then to bank them up with earth, in which condition they remained through the winter. I believe, however, that the Globe Artichoke is much hardier than was at that time supposed. Four years ago I planted a few plants, with the view of testing their hardiness, in a plot of land not at all favourable for their growth, and they have never had any protection at all; nevertheless, they have never suffered injury from exposure to the weather. In the southern and midland counties, all the protection they require is, in severe weather, to place a small forkful of litter over and round the crown of each plant, to be removed when the weather changes. Globe Artichokes are often allowed to remain too long in one spot, and, where this occurs, it has the effect of inducing a large production of heads in July, whilst later in the season there will probably be a scarcity. The best way of managing them, according to my experience, is to re-plant about a fourth of the whole crop every year. The crop will thus occupy fresh ground every four years. One of the principal advantages of this system of culture will be the extension of the season of bearing. The old-established plants will come into bearing first, whilst those that are transplanted in March will, in consequence of their removal, come into use much later, and, so form a desirable succession. In making new plantations, with a view to autumn production, I do not think it is desirable to plant very small bits, and neither is it necessary, as, in removing a fourth of the crop, good strong off-sets, with a good root attached to them, can be selected for re-planting. I need scarcely say that the ground should be in good heart and have been previously deeply-worked. They may be planted in rows, 3 ft. apart in the rows, and 4 ft. row from row. In very hot dry weather, they will be much benefited by being mulched with half-decayed manure, and, as the heads are cut for use, the stalks that bore them should also be removed, as they only help to exhaust the plants. There are several varieties in cultivation, but the best we have here bears a dull purplish-coloured head, with the scales turning in at the top. They may be raised from seed, and in the course of the last fifteen years I think I have raised two batches of seedlings; but, they are not to be relied on. Many of the seedlings will produce small worthless heads, and they are so easily increased by division of the roots, that raising plants from seeds is unnecessary, unless for the sake of experiment.

E. HOBDAV.

A New Salad.—A correspondent (M. D. Guinéneuf) informs us that last year he observed in the market gardens in the neighbourhood of Brussels a vegetable which he had never previously seen in cultivation. He describes it as a sort of Chicory, which forms a neat little head about 5 inches long and 3 inches across, very much like a dwarf Cos Lettuce. It is very extensively used by the people of Brussels during the winter and spring months, the blanched leaves resembling the Barbe de Capucin in flavour, while it is as easily grown as the Dandelion. The following is the mode of culture pursued at Brussels:—It is sown in spring, either in lines or broadcast; the seedlings are either thinned or transplanted, and, during the summer, require no other care than hoeing and weeding. In autumn, the plants are taken up and replanted in a deep trench or in rows, so as to have about 10 inches of soil above the neck of each plant. In this way the leaves are blanched, and, before they have reached the surface of the soil, the plants should be taken up for use. The plants are also forced in the open air by digging alleys between the trenches and filling them with fresh manure. Our correspondent recommends this excellent winter salad very strongly to the notice of our London market-gardeners.

THE FRUIT GARDEN.

THE PEACH ON OPEN WALLS.

By T. BAINES, Southgate.

THE frequent recurrence of severe spring frosts, which we have experienced within the last twenty-five years, have led many to come to the conclusion that the climate of England (so far, at least, as extreme low temperature during the months of April and May is concerned) has undergone a change, such as Mr. McNab supposes has occurred in the climate of Scotland. The observations now carefully taken and recorded in almost every county in the kingdom, will, in years to come, be of some assistance in determining the extremes of temperature occurring in each locality. So far as my own observations have extended in different parts of the kingdom in which I have happened to reside, there has been greater local difference in the extreme low temperatures that have occurred in the spring months than during the winters, and this independent of low-lying situations, the character of soils, or other local circumstances which are generally accepted as exercising an influence over temperature. The ability of any given species or variety of plant to withstand the effects of the weather for a series of years, sufficiently long to enable us to draw a comparison with how it fared in a corresponding period previously, is urged by some as a fair means of comparatively estimating the weather we now experience with that which occurred in years preceding. This test I look upon as uncertain in the case of plants under artificial cultivation, inasmuch as the treatment they at present receive may be somewhat different from that to which they were subject during the time compared with the present. The frequency with which our hardy fruits (or such as are usually grown with the protection of a wall) suffer from spring frosts, is often held up as proof of our springs being more severe than they used to be; but, will a conclusion, based on this assumption, bear investigation? Are our hardy fruits, or more particularly such as we grow with the assistance of a wall (especially Peaches and Nectarines), so well calculated by the treatment they now receive, to withstand the effects of spring frosts as they were in years past? I am not speaking of places where wall fruits receive all the attention necessary or possible, but I am alluding to the far greater number of places where they do not receive such attention as they used to get in times past. Within the last thirty years a partial revolution has been brought about in gardening through cheap glass, and the more general use of hot water as a medium for heating glass structures. In any place, large or small, where a hundred plants of all descriptions were required twenty years ago, a thousand are wanted now, and in most places without additional hands to meet the increased labour involved. Is it then to be wondered at if the attention to wall fruits, as well as other things, falls off to the lowest point? Consequently, this most important branch of gardening is left neglected.

Frost-resisting Power of Bloom.

From close observation, I feel convinced that the state in which a fruit tree is found in the autumn, when the leaves fall, has a good deal to do with the power which its bloom has to withstand a low temperature whilst in flower the following spring. I am aware that this is opposed to the ideas entertained by some who maintain that a certain amount of frost occurring whilst a tree is in bloom will destroy the crop, no matter under what condition its bloom buds have been formed. It is now some twenty-five years since I was first led to notice the partial effects of frost on fruit bloom. During some alterations that were in progress, in the autumn, a number of full-sized Gooseberry and Currant bushes, along with some Apple trees that had been planted seven years, had to be removed; they were taken up with care, all the roots possible were preserved, and they were transferred to a quarter already partially occupied with similar trees. They were removed early in October, whilst there was yet considerable heat in the soil, and I have no doubt their roots would begin to act at once; but, from their size and the length of time they had stood in the place from which they were removed, it will be easily supposed

that they made very little growth the following summer. Their efforts were almost wholly confined to forming fruit buds, which they did to such an extent as to present in the autumn, when the leaves fell, which they did a fortnight earlier than the surrounding trees that had not been moved, a mass of plump buds to the extremity of the branches. The spring following we had a repetition of severe frosts, accompanied by cutting east winds, during the blooming season. Fruit of all description was a failure in the neighbourhood; yet the trees that had been removed bore good crops, more especially Currants and Gooseberries. We had more fruit on one of these bushes than on twenty that had not been moved. Now, what were the conditions under which the bloom buds of these trees were formed and matured the preceding summer? Just simply such as pre-disposed the trees to a fruit-bearing state; all their energies were directed to forming and maturing the embryo fruits, which, consequently, possessed a vigour and vitality such as made them capable of withstanding a lower temperature than trees that were more disposed to the formation of wood. Since that time I have had many opportunities of confirming the conclusions I then arrived at, and from that time I have been a firm believer in either root-pruning, or re-planting, according to the nature of the trees and the circumstances under which they exist. There are other causes that exert a similar influence on the cold-resisting powers of the bloom. I am now speaking of fruits in general, whenever we have an exceedingly dry time early in the summer, so that growth gets checked somewhat prematurely, and afterwards we get copious rainfall early enough for the trees to push growth freely again—this growth coming at a time when the energies of the trees should have been at rest, and the ripening process proceeding, never has the chance of getting fully matured; and, I have noticed, without exception, that the following spring it takes a less amount of frost to destroy the fruit crop than after an autumn when the trees were enabled more fully to mature their wood and bloom buds. Anyone who takes the trouble to observe, will see that this badly-ripened bloom, when it is expanded, is much smaller, according to its kind respectively, than the same variety of tree produces when it has been well ripened, and it is often structurally deficient. Strawberries, after a dry season, do something to confirm this view. If, immediately after the crop is ripe, they suffer severely for want of water, they frequently have no bloom the following spring; if they suffer in a less degree, they will throw up flowers, but they are at all times weak and puny, and the least frost, whenever it may occur, destroys them.

Importance of Water at the Root.

But it is the Peach that has done more to confirm the views I have formed on this subject than all other fruits. Indigenous to those districts of Persia where the atmosphere is considerably moist, and the soil knows no drought; it suffers under cultivation in this country from a want of water, especially at the root, to an extent to which no other fruit is subject. The quantity of water that it will bear, and which it absolutely requires to do justice to it, is not understood by all who attempt its cultivation, and this not confined to any particular portion of the season, but through the whole course of the existence of the plant. If proof of this were needed, it would be found in the magnificent old Peach at Chatsworth, which grows in a situation where there is an impossibility of its roots ever being in a state even approaching to dryness. It is now some years since I saw it, but in the number of things to be met with there, of an extraordinary character, there was nothing with which I was so much struck as this tree, and I understand that it is now in as fine condition as ever it was. The cultivation of Peaches under glass, in such parts of the country where they refuse to grow in the open air, is simply a necessity; even where they will do without such assistance, it gives us the advantage of having them some three months earlier than they can be had on open walls, and, consequently, lengthens their season that much. With this fruit, as with other things, where the cost is incurred of providing a glass covering, wherein to grow it, the chances are that all the attention necessary to ensure success will be bestowed upon it. Yet, even here, in the matter of water, it is often allowed

to run short, especially with those who think that, during the season in which it is at rest, it may, or ought to, be allowed to become dry at the roots; hence the showers of falling buds, at a time when they are expected to open nicely. But it is on the open walls, in such parts of the kingdom where it will succeed, that I plead for its receiving that attention which it well deserves, but which it frequently does not get. In fact, it has become fashionable for some writers to assert that the time has come when its cultivation in the open air ought to be abandoned. My reply is, when it refuses to bear well after it has received the same amount of attention in the open air that is bestowed upon it under glass, it will be time enough to give up its culture on open walls. What are the conditions under which it is often found to exist? No attempt is made to loosen the branches from the walls, to counteract the effect of the sun acting on the brickwork during the winter, and causing the bloom to open much sooner than it ought to do.—To supply this omission, resort is had to shading—sometimes, overdone—at other times, deficiently. And, if the trees get safely through the blooming-season, where the syringe or garden-engine is used every day on the

sary to resort to thicker moveable covering. During the growing season, whenever the soil gets too dry, I give the whole border a thorough soaking every week, by applying from 100 to 150 gallons of water to each tree. In addition to regular copious washing overhead with the garden-engine, I never allow the trees to get smothered with useless wood, nor yet reduce it to the opposite extreme, or remove it too suddenly—thus, arresting the free development of roots, which are essential to the healthy condition of the trees. I encourage as much foliage as can receive the requisite light and air, without unduly shading the fruit. Trees so treated mature fruit double in size and quality to the starvelings so often met with; and, if in a situation and soil not absolutely unsuited to the growth of the Peach, go on improving, instead of the continual re-planting required where the trees receive an insufficiency of water, with its certain consequences of all the insect pests that will live upon them. Even trees that have been half-killed by a course of bad management, in the way described, will recover surprisingly with good treatment. It is often said, that any weakly Peach or Nectarine will flourish, if it is covered with glass. So they generally do; but, continue

Palmette Verrier (see page 263).

trees in the Peach-houses, those on the walls are operated upon, perhaps, once a week, or seldomer. The result is green fly, red spider, and thrips by the million, draining the trees of their sap; this, of course, produces a crop of fruit deficient in both quantity and quality.

There is yet another cause that is much more fatal to the ensuing year's success. It is the deficiency of water at the roots in June and July, after which we often get a copious rain-fall, which starts the trees off growing again at a time when they should be ripening their wood and bloom-buds. This unseasonable growth never has any chance of ripening, the winter is on before it has time; the result is, an insufficiency of bloom of the most weakly description, totally unable to withstand anything approaching trying weather; often composed of little more than calyx and petals: the pistils and anthers being malformed or absent. As soon as bloom begins to open, I put on the coping-boards (10 inches wide), to which are hung old fishing-nets, fastened to stakes driven into the ground, 18 inches away from the wall; these are never removed until the fruit is set. It is all the protection they receive, but the garden here is on the top of a hill, where there is rarely so much chilly vapour as in lower situations; in such places it is neces-

to treat them with the inattention that too often has brought about their unsatisfactory condition, and there will not be much improvement. Their improved condition is generally traceable to the additional care bestowed upon them after the house is erected over them. I do not mean to ignore the untoward effects which our proverbially fickle climate, frequently has upon our best efforts; but, I demur to more being laid to its charge than it deserves; or to the doctrine that the time has come, when the cultivation of the Peach on open walls should be given up by resorting to its cultivation under glass exclusively.

Cropping Peach Borders.

As to cropping Peach borders being admissible, a difference of opinion exists; some maintain that nothing should be grown over the roots. In this, as in most other matters connected with a garden, circumstances will determine the proper course to follow. Where a sufficiency of warm sheltered borders for all purposes exists without growing anything on the Peach borders, it is a mistake to plant on them; where the reverse is the case, some things with good management may be grown on them with little or no ill effects. The worst circumstances that arise are where there is any deficiency

of water in the summer, the evil is augmented by the additional extraction of moisture from the soil by whatever crop is grown on the border; but, where there is no stint of water, that will not occur. Whatever is grown must be something that will not necessitate any disturbance of the roots of the trees. A row of Lettuce is very useful near the wall, but there is the objection that they generally rear a progeny of green-fly, that finds its way on to the trees as soon as they have any leaves upon them. My own practice is to keep one-half the length of border under Strawberries, the plants being 2 feet 6 inches apart each way. These stand three years; the soil is never dug between them. The hoe is used to keep down weeds, and a good mulching of littery dung, fresh from the stables, is applied in March. The other half border is cropped with early Peas for three seasons; after which it is planted with Strawberries, changing the Peas to the other half. I also plant a row of early Potatoes within 6 inches of the wall. The ground under Peas is never dug so deeply as to interfere with the roots of the trees. We apply here all the old potting-soil, as well as such as has been used for Cucumbers and Melons, with a moderate dressing of manure. The almost unlimited amount of water used prevents the trees from experiencing any ill effects from the Strawberries and Peas, which in their turn are all that can be desired, the water benefiting them equally with the trees. The latter are nailed.

Wiring Walls.

I have had wired walls. There is something to be said both for and against them, but, balancing the good against the evil, I consider them as great a mistake as was ever introduced into gardening in a country like ours subject to spring frosts. The object of wiring is simply to save the wall from the effects of nailing, but, as it lessens the protecting powers of the wall, its existence is simply a mistake. We frequently hear it said the face of the bricks should not be nailed into, only the joints. I say never nail into the joints except where necessary for securing the strong branches in their proper places; nail as far as possible into the bricks alone. Let it be done with care, never driving deeper than is necessary, being equally careful not to splinter the bricks when removing the nails. After fifty years use, the wall, if the bricks are good to commence with, will, in reality, be none the worse, the holes not being such as will harbour insects; whereas, if the joints are nailed into, the mortar is so far displaced as to give shelter to whatever insects will live in it. On wires with the shoots from half-an-inch to an inch away from the wall, as this system necessitates, a severe night's frost will frequently kill every bloom; whereas, the same trees, if nailed with their shoots lying absolutely against the bricks, will have enough of the bloom escape for a crop. If anyone who is not fully aware to what the heat absorbed in the south side of a brick-wall during the sunny days that generally precede these frosty nights in spring amounts to, and which is thence given off by radiation, will procure a couple of registering thermometers; hang one where it will be completely away from any disturbing influence; the other, place face-side to the front of the wall, in fact, with the bulb touching the bricks, as do the shoots when nailed; compare the different temperatures registered by the two thermometers in the different positions, and the influence of a wall in warding off frost from anything in absolute contact with it, will be seen at once, as, also, the difference there is betwixt this absolute contact with the wall, and even the distance of only half-an-inch from it. I have often proved this, but never more fully than in the spring of 1872; in that season we had more Peaches and Nectarines, than all I saw collectively elsewhere on open walls. We had 10°, 11°, and 12° of frost, in one week, during the time in which the trees were in bloom, but enough escaped for a crop, the greater portion of it being on the sides of the shoots lying in contact with the bricks. This was more apparent as the fruit began to swell, necessitating the trees being gone over, un-nailing the shoots so as to admit their being wedged up to allow the fruit to swell. Had the wall been a wired one, fifty fruit would not, in all probability, have escaped. I always fully, but gradually, expose the fruit to the sun, by removing all leaves that intercept it, which, consequently,

gives the fruit a very high colour. In that season, when ripe, they had a somewhat strange appearance, on account of most of them being coloured at the stalk end of the fruit, arising from the position which they occupied on the wall. We have now (March 2) finished nailing, being compelled to bring it to a close on account of the forward state of the trees, which are earlier than I like to see them. The present mild winter has had an influence upon them, unaccountable as compared with other kinds of fruit. I have often seen Apricots, Apples, Pears, and bush fruits, a month earlier than they are with us this season. Peaches and Nectarines alone being too forward

Stem Roots of Vines.—Will you inform me if the roots on the rods of an early Vinery are in any way injurious to Vines, or if the cause is from the roots outside not being in good health?—W. C. [Stem roots are often produced on forced Vines, and the cause of their appearance has long been a subject of dispute. Some varieties are much more subject to their appearance than others; for example, the Muscat Noir de Jura almost invariably produces them, no matter in what conditions it is placed. They do not appear to exert any direct influence, either for good or harm, and some of our best Grape-growers look on them with indifference. The generally received idea among practical horticulturists is, that they are produced in consequence of the roots being in a cold wet border, and the branches at the same time in a hot and humid atmosphere. These conditions may possibly promote their formation, but in the large conservatory at Chiswick, where many varieties are planted side by side, all enjoying similar soil, temperature, and humidity, one Vine will produce these roots in abundance, while on its next neighbour, perhaps of the same variety, not a stem rootlet is to be seen. This would lead one to infer that their production is owing to some inherent constitutional condition of the individual Vine; doubtless, the due ripening of the wood assists their suppression very materially. This production of adventitious roots is not confined to the cultivated varieties of the Grape Vine alone, for we find the rambling *Vitis gongylioides* invariably producing pendent aerial roots in great quantities, and often 8 to 10 feet in length, while the tendency shows itself in other species throughout the order, but in a less marked degree.—B.]

Orchards in the Carse of Gowrie.—What (says Mr. McNab, in a paper read the other day before the Botanical Society of Edinburgh) has become of all our boasted Carse of Gowrie orchards, which for a long series of years, half a century ago, used to be so remunerative to their proprietors? We find it recorded from the years 1809 to 1813 inclusive, that seventy varieties of Apples were then cultivated as standards in the Carse orchards, including Ribston Pippin, Nonesuch, Yorkshire Greening, &c.; also thirty-six varieties of standard Pears, including Galston Moorfowl's Egg, Swan's Egg, Jargonelle, &c.; also eight varieties of Plums, including white and red Magnum, Orleans, and Damson. The money produce of the thirty Apple orchards alone, containing in all 126 acres, independent of the Oats, Wheat, Barley, and Grass, frequently grown amongst them, from 1809 to 1813, inclusive, amounting to £10,515. During 1809 the Apples from the 126 acres yielded £2,318; 1810, £2,366; 1811, £1,840; 1812, £2,333; and 1813, £1,668, averaging from £16 to £20 per acre. These orchards still exist, but we hear little or nothing of their remunerative qualities. All that we do learn is that in some years Apples are produced in considerable abundance, and in other years they are exceedingly scarce, but that the average of any five consecutive years is greatly below what it used to be in former times. About the year 1812 it is stated that, in consequence of the remunerative return of these orchards, very large additions were made to them, and all the new varieties of Apples, &c., introduced.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Plum Culture in Oregon.—Dr. Watkins, of Portland, Oregon, informs the *Albany Cultivator* that they have there the finest Plum country in the world—that trees of the Peach Plum, twelve years old the past season, bore 400 lbs.; that every variety ever tried there bears in abundance, the trees breaking down under their loads of fruit, and the insect curculio, which has destroyed the Plum orchards of Eastern America, is unknown.

Grafting-Wax.—How can I make good grafting-wax, and how should it be applied?—S. B. [Grafting-wax is usually made of a mixture of resin, beeswax, and tallow, melted and well-stirred together. The resin tends to make the wax hard and adhesive; the beeswax to impart a durable consistency; and the tallow to make it soft enough for use. A proper quantity of each, to form wax that may be easily applied with some artificial warmth, and that will adhere well, and not melt in the sun, will answer. Sometimes an equal quantity of each is used. Another good mixture is made of three parts of resin, three of beeswax, and two of tallow; but it is cheaper to use more resin, and a common mixture consists of four of resin, two of tallow, and one of beeswax. The resin causes this to adhere a good deal to the hands.]

THE HOUSEHOLD.

Baked Peach Puddings.—Make two pints of sweet cream or new milk boiling hot, and pour it upon a pint and a half of bread crumbs; when half cold, add the juice of a Lemon squeezed upon half-a-pound of powdered sugar and the well-whisked yolks of eight eggs; mix with this two quarts of canned Peaches; put a border of rich paste around a baking dish, and bake from a half to three-quarters of an hour; have ready, whisked to a foam, the whites of the eggs, which, when the pudding is done, spread over its top, and return to the oven for a moment to slightly brown the top.

Preserved Fruit and Vegetables.—Canning fruit has become an extensive industry. The Peach-packing establishments are chiefly in Maryland and Delaware, and there were about 12,000,000 cans packed last year. The Eastern States, New York, New Jersey, and Maryland furnish most of the canned Tomatoes, 18,000,000 cans having been put up from last year's crop. From 6,000,000 to 8,000,000 cans of Corn have been packed. Maine furnishes the best Corn, where also are situated the largest lobster establishments. Pine-apples are largely canned at Nassau, Bahama Islands. In fact, almost any kind of fruit or vegetable may now be obtained for table use in the winter season so canned as to preserve very perfectly the natural fresh flavour.

Lemons wholesome.—When people feel the need of an acid, if they would let vinegar alone, and use Lemons or Apples, they would feel as well satisfied, and receive no injury. A suggestion may not come amiss as to a good plan, when Lemons are cheap in the market, to make good Lemon syrup. Press your hand on the Lemon, and roll it back and forth briskly on the table to make it squeeze more easily; then press the juice into a bowl or tumbler—never into a tin; strain out all the seeds, as they give a bad taste. Remove all the pulp from the peels, and boil in water—a pint for a dozen pulps, to extract the acid. A few minutes boiling is enough; then strain the water with the juice of the Lemons; put a pound of white sugar to a pint of the juice; boil ten minutes, bottle it, and your lemonade is ready. Put a tablespoonful or two of this Lemon syrup in a glass of water, and have a cooling, healthful drink.—F.

Barberries to Preserve.—Boil 2 lbs. of loaf sugar in a quart of water for twenty minutes; then put in your Barberries and let them simmer for an hour; then pour them into a glazed pan. Next day strain the syrup, and add to it another pound of sugar, then let it simmer for half an hour; put in the fruit again, and, when the syrup is about to boil, take it off. When quite cool, put the preserve into proper jars, and tie down with leather or bladder, having brandied paper on the top of the fruit.

Thyme Dumplings.—Well wash some sprigs of Thyme, pick off, singly, a quarter of an ounce of the tender leaves; mix them with the crumb of a penny roll grated, three-quarters of a pound of finely-shred beef suet, a dessert spoonful of sugar, four eggs well beaten, and enough brandy to make it the consistency of paste. Form it into dumplings, flour them well outside, put them into cloths, and boil them for three-quarters of an hour. Serve with wine sauce poured over them.

Black Currant Leaves for Tea.—The *Journal des Connaissances Medicales* contains an article on the virtues of the leaves of Black Currant or Quinsey berries (*Ribes nigrum*). These leaves, when green, are much used by the country people for tea in cases of difficult digestion. With sugar this beverage is agreeable, aromatic, and possessed of exciting properties. M. Blucher of Point d'Ouilly, in the department of the Calvados, has been induced to distil these leaves in the same way as those of Peppermint, Balm, &c., the operation being stopped when the liquid obtained is equal in weight to the substance employed. The leaves should be handled as little as possible, in order not to crush their odoriferous glands. This distilled water is a good vehicle for all stomachic potions, and will keep two years.

Marmalade.—Put 6 lbs. of Oranges (bitter) and six Lemons into a brass pan, cover them completely with water, and boil until soft (about three hours). Lay a plate on the top of the Oranges, to keep them below the water during the boiling. When soft take them out, cut in halves, scoop out the pulp, and throw away the seeds. Scrape the skins free from the white fibre inside, then cut into very thin strips with a silver knife. Strain the water in which the Oranges were boiled—probably now reduced to less than a quart—put it into the pan with 12 lbs. of loaf sugar, another quart of water and the pulp, boil fifteen minutes, add the cut skins, boil ten minutes, and pot.

Carrot Pudding.—One pound of grated Carrot, 6 oz. of bread crumbs, 6 oz. of Raisins, 6 oz. of Currants, 6 oz. of sugar, $\frac{1}{2}$ lb. of suet, half a Nutmeg, half the rind of a Lemon grated, two table-spoonfuls of flour, one egg, and a little salt. Mix all well together, and put into a well-buttered mould. Boil four hours.

THE LIBRARY.

WINDOW GARDENING.*

THE science and art of window gardening, as well as the use of decorative plants in apartments, is, as yet, in its infancy, and its early history seems shrouded in obscurity, although it, doubtless, had its origin in country districts, from whence it found its way into towns. It seems strange that this interesting source of enjoyment should have been neglected for so many years by the horticultural press, but, so it is; while, at the present time, it enjoys no mean amount of literature specially devoted to its progress and advancement. Fifty years ago plants were commonly grown in cottage windows, those more generally employed being *Fuchsia globosa*, Fair Helen Geranium, Musk, several *Mesembryanthemums*, Cactuses, and crimson China Roses. More recently, the newer varieties of *Calceolarias*, *Fuchsias*, *Campanulas*, *Balsam*, and *Pelargoniums* have been employed, while, at the present time, we employ Figs, Palms, Ferns, and the very choicest of exotic plants for the indoor decoration of our dwellings, not only in the quiet country, but also amid the dust and bustle of the busy city. We gladly welcome any work that contributes to the wide-spread influence of domestic floriculture, an influence that contributes so much to our comfort and happiness in the smoky atmosphere of a town residence. Looking at the subject from a commercial point of view, we find many large establishments devoted entirely to the culture of decorative plants in small pots, while thousands of pounds are spent yearly in London for the pretty little decorative plants so often met with in the window cases and apartments of town mansions. We look on the decoration of our dwellings with healthy plants and fragrant blossoms as the sign of a more healthy appreciation of nature as the embodiment of all that is beautiful and attainable in art. We have several very flourishing window-gardening societies established, not only in the metropolis, but also in other large cities and towns, as Hull, Manchester, Nottingham, and Sheffield. Window-gardening is evidently becoming quite as fashionable an amusement for ladies in America as it is with us here at home, and the above work seems calculated to forward progress in this direction, and is full of the most varied information with regard to the culture and arrangement of the various plants most generally used for window and room culture. This information, together with the 250 illustrations scattered throughout the work have been derived from various sources, but, in saying this, we do not wish to infer that the work is less valuable for its power of teaching on that account. The instructions throughout are simple, and, in most cases, to the point, while the book is written in a pleasant unaffected manner, likely to suit its American readers, and contains many hints that would be serviceable to our own window gardeners.

THE IVY.†

WE cannot congratulate Mr. Hibberd on this work. The list of varieties of our common Ivy (all with new names given by the author) is a long one, and contains much descriptive matter; but, after reading through a succession of them, we are forced to the conviction that, in the majority of instances, it would be absolutely impossible to distinguish one from the other, even with the aid of Mr. Hibberd's descriptions. The historical and descriptive chapters contain a good deal of interesting information. The work is copiously illustrated, but the engravings, especially the views, are by no means in a high style of art. Mr. Hibberd has done useful work in his time, but we do not think that the book under notice will add to his reputation, or be of much service to Ivy-growers.

OUR FLOWER-GARDEN.‡

THIS little shilling work will probably be found usefully suggestive to the owners of small suburban gardens who are at a loss to know how to make the most of, perhaps, a limited space. The author states how he effected this in his own case, and, with the help of diagrams and views, gives a very good idea of the manner in which he succeeded. The same plan is not in all its details applicable to every small garden, but something like it may in every case be worked out. The book concludes with a chapter (with numerous illustrations not, perhaps, so good as they might have been) on the construction of miniature ruins for Fern-cases, &c.

THE ARBORETUM.

HARDY TREES AND SHRUBS.

By GEORGE GORDON, A.L.S.

THE TRUNCATE-LEAVED MAPLE (ACER TRUNCATUM).

THIS forms a nice small tree, 30 feet high, with slender, spreading, ash-coloured branches. It is a native of the north of China and Japan, and was first introduced in 1860. The leaves are palmately five-lobed, truncate or slightly cordate at the base, and thin in texture, pale green, quite smooth on both surfaces, entire on the edges, deeply lobed, with the recesses open and rounded, and on very long slender footstalks; lobes ovate, tapering to a long acute point, quite entire, and widely extended; flowers small, yellowish-green, and produced on very long slender footstalks in loose few-flowered terminal corymbs; fruit or keys rather small and quite smooth, with thin flat carpels, and widely extended wings. The length of a full-sized leaf is 7 inches, including the footstalk (which is from $3\frac{1}{2}$ to 4 inches long), and in breadth from $5\frac{1}{2}$ to 6 inches. There is a very handsome Japanese variety of this Maple, called *Acer truncatum pictum*, which has the leaves beautifully marbled with pale yellow. It is the *Acer pictum* of Thunberg's "Flora Japonica," and of the nurseries.

Planting Willows on River Banks.

—I propose, by planting Willows, to consolidate the banks of a winding brook, which are continually being washed away. Which is the best kind of Willow to plant under such circumstances, and which is the best way of planting it? Shall I plant rooted trees or cuttings? if cuttings, shall I plant them upright or in a diamond fashion, like Loudon's Willow hedges? Is Alder as good or better than Willow for the purpose?—RIVALIS. [On submitting this question to Mr. Scaling, of Basford, who is a large grower of Willows, he has kindly favoured us with the following reply:—"After many experiments in the United States, the Department of Agriculture at Washington, has decided that the only effectual way to retain or consolidate the banks of their rapid water-courses is to plant Willows, and that plan is now being adopted. The kind of Willow best suited for that purpose is the *Salix fragilis*, or any of its varieties, or the Huntingdon Willow. Stakes or cuttings are preferable to rooted plants; first, because the banks are not disturbed, or the turf broken by pushing the cuttings into them; and, secondly, all Willows grow better from cuttings than from rooted plants."]

Trees and Shrubs for Sea-coast planting.—In the list which Mr. John Scott gave in your number of the 7th inst. of trees and plants which he has found to succeed in "the most stormy locality . . . on a strong blue Oxford clay, exposed to N.E., E., and S.E. winds, close to the beach, up which the storms often hurled the dashing waves in wild fury, bathing everything in salt and water, and leaving every vestige of vegetation drenched with wet," there occur the names of some which give a widely different result in a similar exposure on the west coast. It is difficult to imagine such plants as *Camellia*, *Rhododendron*, *Escallonia*, *Mahonia*, *Picea Nordmanniana*, and *Horse Chestnuts*, succeeding in the eye of the blast, unless Mr. Scott alludes to small specimens, which are still under the protection of some fence to windward. Probably, the drenching of salt water would not injure these plants; but all experience shows that they cannot stand an unbroken sea blast. *Horse Chestnuts* we have found peculiarly sensitive to exposure, and *Rhododendrons* turn quite brown, although all in the list will stand any amount of frost which can come to them in this climate. It is to be feared that much

disappointment would be experienced if sea-side planters were to take Mr. Scott's list as a guide. On a windward coast, the outermost trees can never be anything but scrub, but it is extraordinary how serviceable the humblest living shelter is in sifting the blast, and how soon trees gradually increase in size behind it, if the soil is genial. The following may be suggested as more serviceable as storm-breakers than Mr. Scott's selection:—*Sea-buckthorn*, *Pinus maritima*, *Pinaster* and, *austriaca*, *Huntingdon Willow*, *Beech*, *Ash* and *Sycamore*. They are named in the order of hardihood and, except perhaps the Willow, are very enduring. The Willow is invaluable as a nurse, for in a favourable season it will make sufficiently long shoots to give material shelter to its neighbours, even though all the life be blown out of the shoots by the following spring.—SALMONICEPS.

Best Time to Cut Timber.—Dr. Hartig, who has made numerous experiments to determine the point, states that March and April are the best months in which to cut timber for building purposes, as it then contains its lowest per cent. of moisture, which he states to be forty-seven per cent. During the three previous months it has fifty-one per cent., and the three following ones forty-eight. He further states that properly-seasoned timber should not contain more than from twenty to twenty-five per cent. of moisture, and never less than ten per cent. If the moisture is removed to a still greater extent, the wood loses strength and becomes brittle. Another

authority states that if trees are felled as soon as they are in full leaf, and allowed to remain undisturbed until the leaves dry up and fall off, the timber will be found well seasoned, the leaves having exhausted all the moisture.

What is the best Low Evergreen Hedge?—I want to make a low evergreen hedge, on the garden side of a newly-planted Quick hedge. Both hedges will be kept cut down to 4 feet, to allow of our seeing over into a paddock. Yew is too dangerous, so near young horses. If *Thuja Lobbii* bears the knife, and could be cut decently as low as 4 feet, it seems the prettiest green. *Siberian Arbor-vitæ* is a better natural shape, but turns, in winter, a dirty brown colour, very inferior to *Thuja Lobbii*. *Phillyrea* is a lovely dark colour, but are there any varieties, dwarf enough, to make a low hedge, without becoming all wood? Chinese Juniper has as lovely a green

as any of the plants just named, but it seems to make a naked stem quickest of all of them. Will some of your experienced readers help me to decide?—PLANTER. [Mr. McNab says—"The plant of all others, for your correspondent's purpose, is the Holly. The Boxwood is also well adapted for such a purpose. If a Conifer is wanted, some of the varieties of *Cupressus Lawsoniana*, particularly the *C. L. viridis* would be superior to the *Thuja Lobbii*."]]

Ancient Yew Trees.—The churchyard at Overton, in Flintshire, says *Science Gossip*, is planted thickly with splendid Yews. One, quite hollow, measured 30 feet in circumference, at 3 feet from the ground. Again, there are twenty large Yew trees in the churchyard at Gresford, in Denbighshire, one of which girths 29 feet in circumference, 5 feet from the ground; it is more than 60 feet high, and is supposed to be about 1,450 years old, planted in the year 426, when the Romans finally left Britain, Wales being at that time a Roman province. These are, however, not so large as the one in the churchyard of Darley, Derbyshire, which measures 33 feet round the trunk, and, though bereft of many of its branches, is still in full vigour. In the churchyard, Tisbury, Dorsetshire, there is now standing an immense Yew tree, which measures 37 feet in circumference. The trunk is quite hollow; it is entered by means of a rustic gate, and seventeen people recently breakfasted in its interior. One in Staines is upwards of 1,000 years old. The great Yew at Fortingal, Perthshire, N.B., is stated by Gilpin, in his "Forest Scenery," vol. i., p. 282, to measure $56\frac{1}{2}$ feet in circumference, and supposed to have existed at the commencement of the Christian era.

The truncate-leaved Maple.

WORK FOR THE WEEK.

Flower Garden.

Where new lawns have to be formed, the preparation of the ground is of the greatest importance, and, except this is attended to in the first place, no after management is likely to be so thoroughly productive of that verdant, close, even, evergreen turf so desirable. Unless good firm turf can be secured, perfectly free from coarse Grasses and weeds of every description, it is best to sow with seeds adapted for the formation of a permanent lawn, being particular that the ground is made evenly solid. Lawns that were top-dressed early in winter, and such as are patchy, will be improved by being sown with Grass seeds and white Dutch clover; afterwards rake and roll over the ground. Finish turfing repairs, and edge the margins of walks. This is a good time, before the ground becomes hard, to grub up Daisies, Dandelions, &c. Sweep and roll the turf; the rolling should be done the day previous to mowing, and lose no time in having the Grass cut with the machine, which will greatly improve the appearance and texture of the turf. Specimen ornamental shrubs should now be pruned. Aucubas, Hollies, Bays, Portugal Laurels, &c., will be greatly improved by going over them with the knife, so as not to lacerate the foliage. The branches may also be regulated, cutting back straggling shoots upon such plants as Junipers, Retinosporas, Yews, Thujas, &c. Unless such plants as the Irish Yew, for instance, are rendered compact by pruning, they break down and often become unsightly. Borders containing herbaceous plants should be manured and dug; and such plants as require it should be divided and replanted. Herbaceous plants are the first to cheer us in spring and the last in autumn; they therefore deserve a little attention. Plant Gladioli either in groups, beds, or lines, keeping the crowns about 3 inches under the surface. That soil is best for them which has been enriched with manure twelve months previously and frequently turned; avoid manure in any form coming in contact with the bulbs, as it is almost certain to generate decay although it gives continuity of bloom. Gladioli should be planted at different times. They are also well adapted for pot culture. Mignonette may now be sown, and also hardy annuals at intervals. Transplant autumn-sown annuals, and thin out those remaining, so as to induce perfect development. Sweet Peas should now be sown.

Greenhouses.

Indoor plants are now starting freely into growth, and must, therefore, be encouraged. Deciduous shrubs and climbers, still unpruned, must now receive that attention, in order to prevent unshapely growth; and all evergreen shrubs may yet be safely pruned, and, if necessary, transplanted or re-potted. Stake plants in pots as requisite, bearing in mind, however, to use as few for that purpose as possible. As the young shoots lengthen, they should be tied out at once to the principal supports. In re-potting, carefully disentangle the outside roots, for plants shifted in a pot-bound condition never succeed satisfactorily. Good substantial loam, skimmed off the surface of a rich pasture, and stacked for twelve months previous to use, with alternate layers of manure, forms an excellent compost for most plants. Wash all sashes requiring that attention, paint any rafters or other wood or iron-work, that seems to need a coat of paint, and scrub off any confervæ or green slime that may collect on the stages. No dirty pots should be used in potting, and the pots in which plants not to be shifted this spring are growing, should also be well washed, and the surface soil cleaned, and, if necessary, a fresh dressing applied. Newly-potted plants should be kept in the warmest corner of the house for a time, and excluded from cold draughts, but to plants in active growth plenty of air should be admitted, and abundance of water given. Maintain the gaiety of conservatories and other show houses by means of Hoteias, Spiræas, various sorts of Prunuses, Deutzias, Lilacs, Rhododendrons, Weigelas, and Roses, brought from forcing houses. Keep up a good succession of Hyacinths, Tulips, Narcissi, and Crocuses, and for late bloom remove some of the latest of these to a cool-house or pit, with a north aspect. Introduce Mignonette from frames, and, if necessary, sow a fresh supply in pots for summer blooming. Rhodanthes are charming plants, both for summer and autumn decoration; therefore sow some at once in 4 and 6-inch pots, or in pans, and, when ready, prick the young plants out into pots, keeping them near the light, and pinching them at the third joint.

Stoves.

Finish potting the principal hard-wooded occupants of stoves as early as possible. *Alocasia Veitchii* and *Lowii* are plants which are frequently not well-grown, chiefly through being potted in unsuitable soil. They do not like anything of an adhesive nature; they do best in one-half fibrous peat, one-half chopped Sphagnum, with a liberal

admixture of sand. *Alocasia metallica* enjoys the same materials. The more easily-grown *Alocasia macrorrhiza variegata*, on the other hand, requires a different soil. Good turfy loam two parts, rotten dung one part, with sufficient sand to secure quick and thorough drainage, suits this plant well. Palms may now be potted, using fibrous peat, with a moderate admixture of broken crocks and sand; being water-loving plants, unless well-drained, the roots become unhealthy. With longer days, the temperature of the stove ought to be increased 8° or 10° during the daytime, and 5° at night; closing early so as to shut in the sun's genial warmth, which is much better, as well as more economical than fire-heat. Syringe the plants at the time of closing the house; and always let this be done sufficiently early to allow the foliage to dry before night. Stoves that face the south, or in gardening phraseology stand east and west, will require slight shading during sunny weather; at least some of the occupants will need a little shade, and it is better to place such at one end of the house, and only shade that portion; as the less shade the better, if scorching can be avoided. Stoves that are built north and south do not require shading so early in the season.

Indoor Fruit Department.

Pines are now being cut in good condition; others are swelling, flowering, and coming on in succession. To those ripening fruit, give but little water; whilst, to those in a less advanced state, supply it more liberally. For suckers, maintain a temperature of 65° at night, and to those farther advanced allow 70° by day, with a rise of 10° by means of sun-heat. Keep the bottom-heat at about from 75° to 80°. Give weak manure-water at the root, and also sprinkle the plunging material and paths with it. To late Vines give abundance of air, so as to keep their buds back. Vines that are just started should be kept close and freely syringed, thinning both bunches and shoots as they require it. The farthest advanced Figs should have a night temperature of 60°; these should now receive plenty of water overhead as well as at the root. The second house may now have the same temperature as the first; the third one kept at 55° at night, allowing a rise of 10° by sun-heat. Peaches, Nectarines, Apricots, and other fruits should be well syringed, except when in flower, and due attention should be paid to thinning the fruit, as soon as it is tolerably well set, and again after stoning time.

Kitchen Garden.

The value of trenching and ridging ground in winter has been made fully apparent this spring, for, while plots that were dug only, have been hardly workable, the ridged ground crumbled down like dust, even although there has been little frost; and, indeed, it is upon such ground we depend for our early Cauliflowers, Lettuces, Peas, Potatoes, &c. Sow a little Salsafy, Scorzonera, and Skirret in lines about a foot apart; the first or second week of next month is the general time for sowing these; but in late localities they should be sown earlier. Of the three, Scorzonera is the greatest favourite. Sow a full crop of Savoys, Broccoli, and Brussels Sprouts; sow, also, some seeds of Asparagus in lines 18 inches apart; likewise successional crops of Radishes, and occasionally some Lettuces, both Cabbage and Cos kinds. Also plant out winter-raised or protected Lettuces between Cauliflower plants, or transplant a full crop over Seakale or Horseradish plantations. Finish transplanting Onions, and, if not already done, sow the summer crop at once. Sow Round Spinach between rows of Peas, or, in some other places, in quantity sufficient to meet the demand; sow also some of the New Zealand Spinach in heat for a summer and early autumn crop; this variety often affords fine succulent leaves, when ordinary Spinach cannot be had. Of Carrots sow a full crop in deeply-trenched ground, which should get a good dressing of fresh air-slaked lime. Sow some small kinds of Turnip in lines a foot apart, or in beds 4 feet wide, on warm, light soil. Earth up and stick Peas as they advance in growth; any exposed to cutting winds should have the assistance of a few evergreen branches to break its force. The following are first-rate sorts for sowing about this time, viz., Champion of England, Laxton's Prolific and Quality, Veitch's Perfection, Dixon's Favourite, M'Lean's Best of All, Prince of Wales, Wonderful, Fairbeard's Surprise, Victoria Marrow, Knight's Tall Marrow, British Queen, and Ne Plus Ultra. Transplant Cabbages as required. Lift, divide, and transplant pot herbs, and sow in a frame some for planting out in May or June. We have never seen strong loamy soils work better than they have done this year, up to this date, for the rainfall in January and February was below the average; and the months of October, November, and December, in 1873, were, likewise, very dry. All kinds of early vegetable seeds have, therefore, been sown in most cases in good condition, and, should the spring be favourable, there is a good prospect of abundance of both vegetables and hardy fruits.

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC SOCIETY.

MARCH 25.

THERE was a nice show of stove and greenhouse plants, Hyacinths, Cyclamens, Orchids, Roses, and early spring-flowers on this occasion. Hyacinths were, in many cases, the same as those staged at South Kensington on the 18th. The most interesting portions of the show consisted of the new plants.

New Hyacinths were staged in fine condition by Messrs. Paul, Messrs. Cutbush, and Messrs. Veitch, the latter having twelve very fine varieties. Foremost here, as at Kensington, was Anna, a fine waxy-white (double spike); Ida, soft canary; De Candolle, bronzy-blue; Fabiola, dense spike, rosy-salmon; Lady Palmerston, soft rich rosy-lilac (fine spike); Vuurbaak, dense spike, vivid crimson; La Joyeuse, soft rose; Czar Peter, fine single blue; and King of the Blues, a fine spike of deep velvety-blue bells, of good substance. Messrs. Cutbush had two new varieties in their collection, viz., Christine Henderson and George Peabody, both noted above. Amongst private growers, Mr. James Douglas, gardener to J. Whitbourne, Esq., Loxford Hall, Ilford, took the leading position, and staged a dozen fine varieties, the best being De Candolle, La Grandesse, Czar Peter, Vuurbaak, Von Schiller, Sir Garnet Wolseley, fine single purple; Lord Byron, fine single blue, with very fine waxy bells; Erebus (new), a deep purplish-black, with a very dense spike. Mr. James Weir, gardener to Mrs. Hodgson, Hampstead, had a nice collection, the best whites being Mont Blanc and Queen of the Netherlands, both single; Baron Von Tuyll, Marie, Hadyn, and Grand Lilas, single blues; and Von Schiller and Macaulay, single reds.

Tulips.—Nice collections, three bulbs in a pot, were staged by Messrs. Veitch, Messrs. Cutbush, Mr. Douglas, and Mr. Weir. The single varieties, as here staged, are very ornamental, and vary in colour, from pure white, through all the shades of lilac, rose, scarlet, and purple, many being either feathered or flaked with rich golden-yellow. Among the best varieties are the following:—Rouge Luisante, fine deep rosy-lilac; Wouverman, deep purple; Prosperine, silvery-rose; Vermilion Brilliant, scarlet and yellow; White Pottebakker; White Canary Bird, clear yellow; Princess Helena, white; and Chrysolara, a bright golden-yellow, very effective, contrasted with the deep purple varieties.

Stove and Greenhouse Plants.—Mr. Ward, gardener to F. Wilkins, Esq., of Leyton, staged twelve nicely-grown plants containing good specimens of *Lycaste Skinneri*, one of the most profuse-flowering of winter Orchids; *Odontoglossum Pescatorei*, in fine condition, with five branched spikes, the blooms being larger than ordinary, and one of the strongest plants of *O. triumphans* that we have ever seen. This plant had very large pseudo-bulbs, fresh green foliage, and bore a branched spike nearly a yard long, on which were nineteen fully developed brightly-coloured flowers. This group also contained a well-bloomed plant of *Dendrobium nobile*, one of the oldest and best of its class; and also a fine little specimen of *Cytisus racemosus elegans*, about two feet through; *Eriostemon intermedium*, well bloomed; and a nice plant of *Erica Lindleyana*, a pretty erect-growing variety, much resembling *E. Wilmoreana*, both in growth and flower. Mr. G. Wheeler also had a nicely-flowered group of this class. Azaleas were shown by Mr. J. Ward, well bloomed, the principal varieties being *A. Model*, fine silvery-rose; *A. Borsig*, a fine semi-double white, fine for cutting, as the flowers of these do not fall so quickly as the single kinds; *A. punctata* omnicolor, a pale rosy-striped variety; *A. Charmer*, a fine large-flowered rosy-lilac form, with wavy petals; and *Souvenir Van Peene*, a pale rosy-salmon. Mr. G. Wheeler was second with nice-bloomed plants, one or two being rather weak. This group consisted of *Marie*, pale vermilion; *Gautoise*, delicate lilac, edged with white; *Iveryana*, white, striped with bright rose; *Perfection*, rosy-lilac; and the bright vermilion-scarlet *Chelsonii*, which is now, however, superseded by the still more vivid *Stella*. In the miscellaneous groups, some interesting plants were staged by Messrs. Veitch, Messrs. Rollisson, Mr. B. S. Williams, Messrs. Jackman, and others. One of the prettiest features in the exhibition was the remarkably well-grown pot-specimens of *Clematis*, staged by the last-named firm, and to which, as will be seen on reference to our prize-list, a special award was made. Being quite distinct from any other decorative plants, and as they may be had in bloom all the year round with but little trouble, we may anticipate their more general cultivation at no very distant date, especially as they are equally well adapted either for conservatory decoration or summer and autumn bedding. Their great star-shaped flowers vary in colour from pure white through all the shades of soft lilac to the deepest of purples, while as climbing or trailing plants in the cool conservatory or greenhouse they are unrivalled. Messrs. Rollisson & Sons exhibited a very nice group of flowering and foliage plants, consisting of Orchids, bulbs, and choice succulents. In this collection we noticed a fine variety of *Imantophyllum miniatum*, with broad petalled and very richly-coloured flowers; also plants of the old, but beautiful, Fern, *Brainea insignis*, similar in habit to a robust *Lomaria gibba*, but much better in every respect. Mr. B. S. Williams had a nice collection of Orchids, foliage plants, and succulents. *Anthurium crystallinum* is a striking plant, with great velvety-green leaves and bright silvery veins. Among the Orchids shown by the same exhibitor we may allude to the old, but little known, *Ornithidium coccineum*. In habit this resembles an *Odontoglossum*, having fresh green leaves and clusters of small, but vivid-scarlet flowers at their base; *Cymbidium Parishii* (?), and the plant of *Renanthera coccinea*, before

alluded to in our columns. Messrs. Lane & Sons staged a collection of small Camellias in pots, very nicely flowered, as well as a miscellaneous group of spring-blooming shrubs. Messrs. Cutbush, Mr. Toms, and Messrs. Veitch, also staged groups of flowering and foliage plants. The latter firm had a nicely-bloomed plant of *Dendrobium Dominii* the first hybrid in the genus and the result of a cross effected between *D. nobile* and *D. moniliforme*. In habit and flower it closely resembles the last-named parent. Mr. Chancellor, The Retreat, Richmond, sent four nicely-grown specimens of *Mignonette*, remarkable for their large flower-spikes, the perfume of which was most grateful throughout the conservatory in which they were placed. Well-grown pots of *Lily of the Valley* were staged by Mr. J. Douglas, and Mr. G. Wheeler sent a like number with better foliage but far fewer flowers. *Deutzias* were also staged by Mr. Douglas in beautiful condition. These plants were deservedly awarded the first prize. The most important point about them from a cultural point of view was their being old plants trained into a balloon shape, the result being perfect globular masses of fresh green foliage and snow-white flowers, about 2 feet high. The usual way of growing *Deutzias* is to cram as many imported or home-grown plants into a pot as possible, but the plan adopted by Mr. Douglas is well worth a trial. Mr. Reeves, nurseryman, Acton, sent six well-grown bush plants, and Mr. James also sent half-a-dozen plants grown in the usual way. *Cinerarias* were staged in fair condition by Mr. James, and also by Messrs. Dobson & Sons, the prizes being awarded in the order named. The plants staged by both exhibitors were dwarf, compact, and well flowered. *Cyclamens* were staged by Messrs. Veitch and Mr. B. S. Williams in the miscellaneous classes, and also by other market growers. The principle award was made to Mr. Goddard, whose plants were well-nigh perfect in leaf and flower, Mr. James being second. Both exhibitors had well-grown plants most profusely bloomed. Messrs. Lane also exhibited a new *H. P. Rose Souvenir de Romaine Desprez*, a fine flower, of a rosy-lilac tint. Mr. Needle, gardener to the Comte de Paris, Twickenham, sent between forty and fifty pots of hardy Orchids and *Ophrys*, remarkably fresh and healthy, and well-bloomed. These curious little plants certainly deserve more attention than they at present receive, and their cultural treatment is very simple, all they require being a compost of fibrous loam and lumps of limestone on a well-drained bottom, plenty of water when growing, and a cold frame with an eastern aspect.

Cut Flowers.—A nice collection of *Camellia* flowers, in fine condition, came from Mr. W. Paul, of Waltham Cross, who also set up some fine stands of cut Roses, of marvellous quality for the time of the year. Among the new varieties we noticed the following:—*Madame Lacharme*, fine blush white, and a vigorous grower. *Princess Christian*, a soft rosy flesh-coloured variety, fine in the bud. *Derraine Lamy*, fine rich crimson, set off by fine wax-like foliage. This is a vivid flower, very full, and of good form. *Madame de Ridder*, a fine purplish-crimson, with very smooth petals, somewhat resembling *Dupuy Jamain*, but not quite so full, and more distinctly suffused with purple.

Certificates of Merit were awarded to the following New or Rare Plants:—*Chysis Chelsonii* (Veitch).

Cypripedium Harrisianum (Veitch).—This is a beautiful and free-flowering hybrid, raised by Mr. Dominy, between *C. barbatum* and *C. villosum*. In habit it comes nearest to the latter parent, but is distinct from either, and one of the best *Lady's-slippers* in cultivation.

C. Roezlii (Veitch).—This is a very robust-growing species, bearing large long-petalled flowers on a stout scape, which is furnished with very large bracts. It differs from *C. longifolium* in its broader leaves and richer tinted flowers.

C. Argus (Veitch), described in our last week's number.

Cattleya Veitchiana (Veitch).—A richly-coloured cross between *C. labiata* and *C. crispata*.

Lælia Veitchii (Veitch).—This is a new and beautiful plant raised in Messrs. Veitch's establishment, between *Lælia Pilcherii* (also a hybrid) and *L. cinnabarina*. In habit it resembles the latter parent, having deep orange-yellow flowers 3 inches across, with a crumpled crimson lip.

Vanda carulescens (Veitch).—A pretty little blue-flowered species, evidently a very free bloomer. The lateral sepals are curiously incurved, each flower being about an inch across.

Eranthemum aureo-reticulatum (Veitch).—A pretty foliaged plant with pale stems and large oblong leaves, netted with golden-yellow. It is worth growing, and is distinct, most of the other species having red or purple veins.

Adiantum sessilifolium (Veitch).—A fresh green elegant species, having large triangular tripinnate fronds 2 feet high, the pinnae being crisped along their upper margins. This is a distinct and free-growing plant.

Asplenium schizodon (Veitch).—A very distinct species which, at first sight, reminds one of *Lomaria gibba serrulata*. Its fronds are broadly bipinnate and of a bright green tint.

Rapatea (*Saxo Fredericka*) *pandanoides* (Veitch).—A curious plant, nearly related to *Juncus*; each leaf has a sheathing base, and from these the young red-tinted foliage rises like a sword from its sheath. Worth culture as a curiosity.

Boronia megastigma (Veitch).—A slender-growing Heath-like plant, bearing small drooping flowers, golden-yellow within, and of a lurid brown outside. The flowers are very sweet-scented.

Dracæna Baptistii (Veitch).—A robust and striking plant, with broad rosy-tinted foliage. One of the best of all the newer varieties of this genus.

Curmeria picturata (Veitch).—A dwarf foliage plant, having ovate foliage, cordate at the base, of a light velvety-green tint, with a broad irregular silvery blotch or stripe up the centre.

Clematis Vesta (Jackman).—A robust and free pale-flowering variety. Well worth growing.

Clematis Countess of Lovelace (Jackman).—A profuse bloomer. Well worth growing for variety, as are nearly all the plants of this fine genus.

Anthurium hybridum (Williams).—A strong-growing species, having green saddle-shaped leaves. The younger foliage is of a fine deep bronze-like tint, and the whole plant is very ornamental.

Gymnogramma decomposita (Williams).

Agave Taylorii (Williams).—An interesting hybrid, and one of the best of the filiferous group.

Cypripedium Roezlii (Williams).—See above.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

GRAFTING DWARF ROSES.

It may not be generally known how very easily dwarf Roses may be increased in spring by grafting in heat under glass. In this way stronger plants may be obtained, in a given time, than by any other method of propagation with which I am acquainted; the chances of success are also more to be depended on; and, when grafted close to the collar of the stock, in the way which I shall presently indicate, they become, in a short time, virtually on their own roots. In February or March, I secure a sufficient number of one-year-old Manetti stocks, with a supply of well-ripened wood for scions of any kinds of Roses; it may necessary to increase all kinds of Tea Roses do well grafted in this way; but it is important that the shoots selected should be firm, and the buds dormant. If soft sappy wood is used it will damp off to a certainty. The roots may be shortened, and the stock headed back to within $1\frac{1}{2}$ inches of the collar, in fact, leaving only just sufficient room to put on the scion. There are various modes of grafting, but what is termed whip-grafting is that most generally useful for the inexperienced knifeman. This may briefly be described as cutting away a rather large slice from one side of the stock, and, neatly fitting the scion to it, taking especial care that the barks of both stock and scion form a perfect junction on, at least, one side, without which no union can take place, and the whole should be firmly bound together with matting or Roffea Grass (a cheap material, that is now largely sold). As fast as the stocks are worked they should be laid on one side, and the roots covered with damp Moss, or something to check evaporation till a sufficient number are done to fill a hand-light in the propagating-house or any other place, where a steady bottom-heat of 75° can be obtained. The hand-lights should stand on about 6 inches of very light sandy soil, in which the grafted plants should be plunged closely together, or nearly so; at the same time, completely covering the junction of the stock and scion, as this obviates the necessity for using grafting-clay or wax; at least, I have had as much success without its use as with it, but, of course, the air must be excluded in some way, which is done in this case by the plants being plunged above the junction. A hand-light will hold from 50 to 100 plants; and, as each glass is filled, it should receive a watering with tepid water to settle all down. The lights will generally require to be kept close, or if any ventilation is required at all it should be given early in the morning or at night. If all goes on well, in a fortnight or three weeks, the scions will be pushing into growth, and the stocks emitting fresh roots. They should now be taken up and potted separately into 48-sized pots, in about three parts rather strong loam and one part old manure, well broken up, taking care in potting that the stock is completely buried, which, as they are grafted close to the collar, there is no difficulty in doing. Anyone who prefers the common Briar for a stock may raise them from seed, and graft in the same way I have recommended for the Manetti. I have sometimes, when hard pushed for stocks, obtained small Briars from the hedgerows in the neighbourhood, or used some of the old fashioned summer-blooming Roses for stocks; but, of course, the better the stocks in a general way, the more complete will be the success. But, in early spring, when most things are just waking into life, with the growth of the stock just a little in advance of the scion, and a gentle bottom-heat, an inexperienced propagator will obtain a far larger portion of success by this than by any other method. After potting them off, they should be grown on in heat for a time, and then gradually hardened off. As the plants grow, the only care required is to tie up the shoots, and pinch them, so as to form handsome specimens. If they are attacked by aphids, mildew, or the common rose-grub, it will be necessary to use tobacco-water and flowers of sulphur, in the first two cases, and to hand-pick the grubs, as a remedy for the last-named evil.

E. HOBDAV.

LUCULIA GRATISSIMA.

We seldom meet with a really well-grown specimen of this fine conservatory shrub, although it has been long introduced to our gardens; and, of all plants for the winter decoration of a well-lighted and moderately warm house, this is certainly one of the best. We have often wondered why so many cultivators fail with this plant; but could never satisfy ourselves as to the cause, especially as it is by no means difficult to grow. About twenty years ago a specimen of this *Luculia*, which grew in the large conservatory at Chiswick before it was converted into a Vinery, used to be the admiration of both gardeners and visitors. It is rare to see any stock of young plants of this fine sweet-scented shrub in nurseries; though this cannot make much difference to its more general distribution, since it might soon be propagated by the dozen or hundred; but the fact is, there is at present no demand for it. We, however, never knew anyone with whom it succeeded well once who would ever care to be without it afterwards. Only the other day a noted gardener in the midland counties wrote to us to the effect that his plant of *Luculia* had been a perfect picture; it is 10 feet high, and quite as much through, one dense mass of fresh green foliage, and rosy clusters of fragrant flowers. One of the best specimens of this shrub we have ever seen is at Little Dalby Hall, Leicestershire (the country seat of E. B. Hartopp, Esq.), where it occupies a corner of the conservatory, and forms a glorious bank of flowers and foliage 13 feet high, and 9 or 10 feet through. When seen in such fine condition as this, it is one of the most effective of all decorative plants, and furnishes plenty of spray for drawing-room vases or dinner-table decoration. The plant likes a good body of fresh open compost, in which its roots luxuriate, spreading in all directions; still, one occasionally meets with nice little specimens in tubs, but even these would be far better if planted out. A little weak manure-water is very beneficial to this plant when making its growth, more especially in the case of those plants which have their roots confined. If regularly syringed, and a genial temperature maintained, this plant is rarely troubled with insect pests; while any little extra attention bestowed upon it is amply repaid when its flowers make their appearance. We have no other plant that rivals it as a winter-blooming conservatory plant, and it certainly deserves a fair trial everywhere where choice delicately-perfumed flowers are required for decorative purposes. The plant is readily propagated by means of cuttings or layers inserted in a sandy compost in a genial bottom-heat, and when the young plants are fairly established, they develop themselves very rapidly. The plant does well in a large pot or a tub; but, if it is planted out in a good fresh compost of fibrous peat and turfy loam, it develops itself far more rapidly and requires no further attention than occasional syringings, and a good supply of water at its roots. Its great clusters of sweet-scented flowers are generally produced in December, and this makes the plant doubly valuable, as choice flowers are then generally scarce. The plant should be pruned in about the middle of March, and will soon start into growth, especially if assisted by gentle syringings on warm days. Every encouragement should be given to induce the plant to make its growth early and quickly, so that the young wood may get thoroughly well-ripened in the autumn, as this conduces to large clusters, and a far finer crop of flowers. A warm sunny position should be selected for the plant, and the compost should be placed on a well-drained bottom. We have seen very pretty well-bloomed plants trained along the back-wall of a plant-stove; but a warm conservatory is the proper place for it, and a good specimen should find a place in every garden, however small. The plant is a native of northern India, being found in tolerable abundance throughout Nepaul, forming a beautiful tree. Another species, *L. Pinciana*, still more rare, and it is, if possible, still more beautiful than the last-named, succeeds under the same treatment. It has clusters of white flowers, and is readily distinguished from its congener by a row of small scales around the tube of the corolla. Like the last it is deliciously fragrant, and first flowered in Messrs. Pince's once noted collection of rare exotics; and it was so highly valued that they sent a special messenger with cut flowers for figuring, and a living plant for the Royal Gardens at Kew.

B.

NOTES OF THE WEEK.

— PUSCHKINIA SCILLOIDES, a beautiful plant, belonging to the Liliaceæ, is again blooming in Mr. Parker's nursery, at Tooting. It bears a loose spike of pale blue flowers. It is a native of southern Russia, and is, as yet, rare in gardens.

— WE are indebted to Mr. Barr for a sight of the true double Daffodil, a very different plant from that usually so called. Both the true Daffodil and its double variety are plants of medium growth, and bear bright yellow flowers of handsome form, set in a sulphur-coloured perianth. It is a rare and valuable species.

— ONE of the finest specimens of the beautiful *Phalænopsis Schilleriana* now in cultivation is at Yewfield House, Arbroath. It is furnished with fourteen leaves, which vary from 14 to 18 inches in length, and it has this season borne four spikes, on which there are altogether 209 fully-expanded flowers. In the same collection is a fine specimen of *Angræcum sesquipedale*, having sixteen fine flowers on four spikes. Than these finer specimens could not well be had.

— IN Mr. Barr's trial grounds, at Tooting, may now be seen at least twenty species and numerous varieties of early-flowering *Narcissi*, many of the forms being exceedingly rare. Of these *Narcissi* many are well figured in Parkinson's "*Paradisus Terrestris*" as long ago as 1656. Among the more conspicuous of those now in flower may be named *N. obvallaris* and its variety *maximus*, *Telamonius* and its double variety, all fine kinds of Spanish origin.

— IT is in contemplation to secure Brook Green, Hammersmith, permanently, for the public. The Ecclesiastical Commissioners have offered to give up their rights over it for a nominal consideration, if the Metropolitan Board will undertake the charge of it. The Board has expressed its willingness to accept the surrender of the Commissioners' rights, and to put the green in order, provided it is maintained afterwards by the parish to which it belongs.

— DR. MOORE writes to us to say that a fine plant of *Darlingtonia californica*, raised from seed sown in 1868, is now in flower in the Botanic Garden, Glasnevin. It has continued healthy throughout, and has now leaves on it more than 18 inches in length; the flower-stalk is upwards of a foot in height. It may interest our readers to know how long they may expect to wait for seedling plants of this to flower, even under good cultivation. The plant at Glasnevin has been grown, during the last three years, in a cool greenhouse, where it is now flowering. During the first two years after it germinated, it was kept in an intermediate house.

— IN South Australia something effectual is about to be done to secure an adequate supply of timber. A scheme is on foot for laying out no less than 300 square miles with a great variety of timber trees. The first step will be to proclaim the necessary number of reserves. Of these twenty-nine are to be in the northern, thirteen in the southern, and eighteen in the central districts. An officer practically versed in forest culture is to be appointed conservator. The trees selected for cultivation are in all cases to be such as will be useful for manufacturing, building, fencing, and mining purposes. In the list we observe *Eucalypti*, Pines, Oak, Cedar, and other woods. The forests in question are to be formed gradually. At first the trees will be planted in the reserves about 10 feet apart, or 435 to the acre. At the end of five years every second tree is to be removed and sold, and a similar thinning out is to occur five years later. The remainder will consequently have a sufficiently clear space in which to attain the fullest maturity; 7,000 acres are to be at once "reserved" for the reception of 3,000,000 of plants, which it is estimated can be raised during the first season at the principal nurseries of South Australia.

— THE important project of an irrigation canal from the Rhone, in reference to Vineyards and the *Phylloxera*, set on foot by M. Dumont, has received the approval of the Conseil de Générale des Ponts et Chaussées, and will now be submitted to an inquiry of public utility in the five departments, Isère, Drome, Vaucluse, Gard, and Herault. Thereafter a law will probably be proposed and passed this year. The works will then begin in 1875, and be concluded before 1880. As the scheme now stands, it is to ensure the irrigation or submersion of more than 1,640,000 acres of land. Two-thirds of this surface are planted with Vines, and have been more or less attacked by *Phylloxera*. The formation of such a canal appears to present the only practical means of saving this source of national wealth, the average product of which at present exceeds 300,000,000 francs (while the canal will cost about the third of this, or 100,000,000). It is expected to increase by half a milliard the value of the land. M. Dumont further points out that an immediate consequence of the submersion of 1,640,000 acres will be a change of the climate of this zone, as has been found to be the case with the canals of Marseilles and Suez. It appears to be getting recognised in France that it is hope-

less to think of exterminating *Phylloxera* thoroughly in Europe. Hence the necessity of a profound modification in cultivation of the Vine, consisting in giving each Vine-cultivating district, as far as possible, the means of artificial irrigation or submersion.

— WEST Ham Park is, we understand, to be opened to the public early in May. The committee of managers is to consist of fifteen members, of whom eight are elected by the Corporation of London, four by Mr. Gurney, and three by the subscribers to the fund.

— BICTON, the seat of Lady Rolle, was, says the *Pall Mall Gazette*, partly destroyed by fire on Monday last. The fire broke out in the laundry and spread with surprising rapidity. The damage is estimated at about £10,000. The conservatory is reported to have sustained considerable injury.

— OUR cultivated plants survive much farther to the north than is usually supposed. M. Adolph Erman, when only eighty-four miles from the Arctic Circle, in North Siberia, found not only woods of Larch, Pine, and Birch, fine and vigorous, but garden vegetables, such as Turnips of large size, and in the woods Blackberries and Roses—probably, says M. Erman, *Rosa calyciflora* of Gmelin—growing luxuriantly.

— AT a meeting of the Helensburgh Horticultural Association, the other day, it was stated that 245 species and varieties of plants, representing eighty-two genera, and illustrating forty-four natural orders, had been in flower in the open border since the new year. A botanical work fully 290 years old, was laid on the table, in which reference is made to the *Cyclamen*, as being spoken of by Pliny as early as the year 75 of the Christian era.

— MR. PRESTOE writes to us as follows, respecting the wireworm:—"I find the temperature of the soil, this season, to be much higher than I have known it for years, and, in consequence of this the wireworm will become a beetle six or seven days earlier than it has been for the last ten years; those who are planting Potatoes and other crops likely to suffer from it will do well to look out for, and destroy, the larva, which is now in a very active state seeking a resting place, in order to become a pupa; this is its third transformation."

— THE arrangements for the forthcoming opening of the Walsall Arboretum on the 4th May are fast approaching completion, when the inhabitants of Walsall and neighbourhood will be provided with a place of healthy recreation. When the arboretum scheme was first laid before the public, many were of opinion that it would be practically impossible to carry it out; but all who have been connected with it have, by dint of hard-work, overcome the numerous difficulties which at first beset them, and the arboretum grounds will, ere long, be the chief centre of attraction of their kind in South Staffordshire. Whilst the boundaries and lodge present a somewhat sombre appearance, the visitor is agreeably impressed on entering the interior of the grounds with their beauty. There are numerous silvery and Mossy groups of plants, cushions of bright green foliage, panicles of rosy flowers, margins of well-defined botanical species with prettily marked foliage, and spring flowers peeping out nearly everywhere, thus affording a variety that cannot fail to meet with universal admiration.

— THE production of Saffron, says the *Journal of the Society of Arts*, is considerable in France, but it is confined to three departments, of which Loiret produces the largest amount and of the best quality. It is a peculiar industry, and little known even in France. A Saffron field is not in full bearing till the end of the second year, and at the end of three years it is exhausted, and, according to the local proverb, the land is then so poisoned that it cannot be used for the same purpose for fifteen or sixteen years more. The average crop of the second and third year is various, from ten to thirty kilogrammes per hectare, or from 9 to 27 lbs. per acre, of dry pistils; each acre produces about 600,000 to 700,000 bulbs, and each bulb two or three flowers. About 30,000 flowers are required to produce 2lbs. of fresh pistils, which, when dried, are reduced to one fifth of that weight; the pistils are the only productive portion of the flower, the rest is waste. The labour of picking such enormous quantities of flowers by hand is great, and when the crop is large, and labourers scarce, the flowers are carried into the villages and small towns round about, to be picked at home. The farmer has to pay from about 10d. to 4s. a pound for the picking, according to the abundance of the crop. When the pistils are separated they have to be dried, and this operation is effected by placing about a pound fresh pistils at a time in a horse-hair sieve, suspended over a little charcoal furnace. As soon as it is dry the Saffron is ready for sale. It requires a peculiar soil, and the land which suits it is worth £3 to £4 per acre, or double the rent of ordinary land in the same district; but the Saffron itself sells, on an average, for 30s. to £2 per lb., and, when very fine, for double those rates; in very extraordinary years, which, however, occur only once or twice in a century, Saffron is worth as much as £8 per lb.

THE INDOOR GARDEN.

ORNAMENTAL FRUITED PLANTS.

In addition to the descriptive list of "Berry-bearing Plants," given at page 436 of last volume, we have others which, if not so generally grown, are not less interesting on that account. Some plants, of which the common Butcher's Broom (*Ruscus aculeatus*) may be cited as an example, bear inconspicuous flowers, hardly perceptible to the naked eye; but their fruits render them as ornamental as the generality of flowering plants. One of the prettiest of these (and one which is now becoming extremely popular for winter decoration) is the scarlet-berried Gladwin (*Iris foetidissima*), a plant that grows and fruits well on any warm sandy border in the South of England. Some of the *Pæonies*, again, bear great brown woolly capsules, which, after their showy flowers are past, when they burst open and reveal their shiny blackberry-like seeds, and the crimson lining of the pods, are even more ornamental than those of the Gladwin. As a miniature berry-bearing plant for the window, we have few that grow better or fruit more freely than the dwarf mossy-looking little *Nertera depressa*, which may be readily propagated either by means of seeds or by division. Seeds of it germinate freely in a pot of light sandy soil, covered with a tumbler or a small bell-glass, and set in the window of an ordinary apartment; or, little rooted patches taken off an established plant, and planted in a pot or small pan of light rich earth, soon become covered with orange-scarlet bead-like capsules or berries. The Golden-fruited Bromeliad (*Bromelia sceptrum*) is one of the most striking of all stove or warm greenhouse plants that bear ornamental fruit, not even excepting the more prolific of the *Granadillas* (*Passion-flowers*), many of which bear very ornamental egg-shaped fruits of a bright golden-yellow, or rich purple colour. Bromelias are easily grown, and, like succulents, they require but little attention beyond occasional watering and syringing during hot weather. Any compost seems to suit them; but a good sandy-loam and well-drained bottom is best. The golden-fruited species has long spinose leaves, and bears an erect spike of flowers, which are not particularly ornamental; but they are succeeded by a cluster of golden-yellow fruits, each as large as a pigeon's egg. Collectively, these are very ornamental, and, if kept dry, they will last for several months in perfection. The crimson-fruited *Carex* (*C. baccans*) is another plant which produces fruit of an interesting kind. It is a robust-growing Himalayan species, well adapted for pot culture, or for planting out in conservatories. It has gracefully recurved Grass-like leaves, from 18 inches to 2 feet in length, and about half-an-inch in width. The most ornamental part of the plant, however, is its clustered spikes of deep vermilion or crimson-tinted fruits, which contrast well with the bright green leafy bracts by which they are supported, each

little fruit shining as if varnished. When seen on the plant these clusters are very pretty, and they last for months in perfection; they are also well adapted for cutting and mixing with choice flowers and Ferns. The plant grows well in a pot in fresh sandy loam, if well drained; it requires a regular and copious supply of water when growing, taking care never to let it become thoroughly dry at the root. The accompanying illustration (which gives an excellent idea of the habit of the plant) was taken from one which fruited last winter in the Palm-house at Kew. The cluster of fruit here represented is, however, little more than half the size which it attains under good cultivation. The plant is easily propagated, either by means of division or seed, and is well deserving of general cultivation. Many other ornamental *Carices* are well worth cultivation, and among our own native species we have one or

two that are beautiful objects planted on the spongy margins of ponds, lakes, or other ornamental waters. *C. pendula* is one of the best for this purpose, and also makes a conspicuous object in drier parts of the pleasure-grounds. I remember that some fine patches of this plant grew well in the old wilderness at Chiswick some years ago, but, unfortunately, these, together with many other rare and interesting plants, no longer exist there. B. F.

Carex baccans.

THE BALSAM.

In old-fashioned days, before the rage for bedding-plants had set in, the Balsam was occasionally used for out-door decoration, and very pretty beds it makes, especially if there be a considerable variety of colours amongst the plants so employed. But, perhaps, the Balsam is most properly classed as a pot-plant, not because it grows better or flowers more freely under glass than out of doors, but, because when elevated up to the eye-level, its beauties are much more easily discernible than they otherwise would be, and the fine double blooms that adorn its branches are seen in perfection. The Balsam deservedly ranks as one of the most effective and most easily grown of all tender annuals. It has been, moreover, elevated to the distinction of a florists' flower, and thus, as a show-plant, it possesses certain merits that render it important. Well-grown and well-flowered specimens are by no means common, simply, because few men know how to do the plant justice; yet so amenable is it to ordinary culture in the open ground, that it is comparatively easy to lift up from thence much finer and much better bloomed plants than any grown in pots under glass. Probably, the reason of the too frequent failure in the cultivation of good plants in pots lies in the fact that the Balsam is rather impatient both of great heat and a confined atmosphere. The first induces drought at the roots and a quick falling of the flowers, whilst the other forces the plant into a somewhat premature and lanky form of growth, which is not conducive to elegance, or to the formation of good specimens. I grow Balsams by the hundred for seed, and, not having in that case the fear of horticultural censors before my eyes, I should

much prefer to grow all that I need in pots, instead of out in the open garden, for the simple reason that one is then able to group all the respective colours together, and also, because seed so produced ripens earlier than in the open air, and the crop is more certain. But there are objections, not the least of which is the great amount of good holding soil required for the growth of several hundred of the Balsam in 24-sized pots; then there is the large amount of house-room needed; and, lastly, the time required to water them—an operation that needs performance twice or thrice a day in hot weather. I sow my seed in shallow drills, in a soil-bed in the greenhouse, about the middle of March, marking each colour with a label, and giving plenty of room, so that the seedling plants may not be cramped for space as they grow. If the season is favourable, they are dibbled out into rows in the second week of May, giving the plants 12 inches space in the rows, and 30 inches row from row; between these, however, I put out either Stocks or Asters, or some other moderate-growing annual, so that the Balsams get plenty of space without wasting the ground. Sorts that grow tall, or furnish a large number of side-shoots, need both pinching and thinning out, as it is best to perfect what flowers have been formed, say to the end of August, rather than look for seed from any bloom after that date. The glorious uncertainty of our climate was most unpleasantly exemplified in September, 1872, when an early white frost caught the Balsams in full growth and vigour, and inflicted considerable mischief on the plants and seed crop. However, such a misfortune seldom happens so early in the year; and if the first frost does not fall until after the middle of October, then the crop is pretty safe.

If lovers of the Balsam were to watch the plants so abundantly sent into Covent Garden Market, they would note that wonderful results in the way of both growth and flower are got out of 48-sized pots, in which all market plants are grown, and also that the sorts sold are limited in colour almost entirely to white, scarlet, and white with scarlet flakes, these being the orthodox marked tints. But the florist, ever on the look-out for novelties, knows no such limitations, and is rather anxious to obtain as much variety in the colours and markings of his flowers as possible; so that the market dealer seldom sees the beautiful sorts that private gardeners grow. After some eight years of Balsam culture for seed purposes, I have been much surprised to find how wondrously its colours and markings have increased; and, although in that time I have had the assistance of but few of the Continental kinds, yet I can now reckon amongst my collection nearly thirty diverse colours, shades, or distinctly-marked kinds; in addition to which I have a dwarf or Tom Thumb strain, that also displays some seven or eight colours and markings—so it is evident that there is now variety enough to satisfy the most exacting. The dwarf strain is most adaptable for pot culture, as they grow to just half the height of the common sorts, and are both robust and free-blooming. Of these there are in colour white, purple, scarlet, scarlet with white blotch, white with carmine flake, and white with purple flake. Of the tall kinds, I have now pure white, white shaded buff, white shaded mauve, and white shaded rose; then white striped and speckled crimson (otherwise called Solferino), white striped and speckled purple, white striped and speckled carmine, white flaked crimson, white flaked purple, white flaked carmine, crimson self, crimson scarlet, deep purple, light purple, lavender, peach, salmon, scarlet, salmon-carmine, rose, carmine, mauve flaked crimson, lavender flaked crimson, scarlet white blotch, purple white blotch, crimson white blotch, and several other shades and markings difficult of description, but still quite dissimilar in appearance. Of course, a good number of plants in a greenhouse or conservatory containing all these diverse colours would, of necessity, present many more charms than a collection of but a few colours; and to exhibitors of Balsams, this variety is not only charming, but a great help to success.

A. D.

come in very useful either for summer-flowering plants or for furnishing cut bloom. As soon as the seedlings have made four or five buds their tops may be pinched out; and, also, those of the laterals, when they have grown about 6 inches in length; give them a liberal shift and encourage them occasionally with a little manure-water. A mixture of half loam, quarter peat, quarter leaf-mould, and a good addition of sand, seems to suit them perfectly. Established plants flower, more or less, all the year round; but, I think it better to dry them off through the winter, and to start them early in spring, thus securing a good bloom through the summer months. Pinching, when the seedlings are little, is absolutely necessary; for, if this operation is delayed too long, they become leggy and do not flower freely. As regards drying off and starting them into growth again, they may be treated the same as stage Pelargoniums.—JAMES MORRISON, *Wotton Gardens, Aylesbury.*

Indian Crocuses (Pleiones).—These rank amongst the most lovely of Orchidaceous plants. They are herbaceous, and produce blooms from October to February; at least a succession of bloom can be kept up during that time. They succeed best when grown in the Mexican or East India house, in pots or in suspended pans, in a compost of Sphagnum and peat, with a little silver-sand; some growers add, also, a small portion of loam. In every case, the plants should be near the light, and, for this purpose, suspended Orchid-pans are more suitable and convenient than pots. All the species are dwarf, and form depressed pseudo-bulbs, from which emanate pale green leaves about 6 or 8 inches in length, which usually turn yellow and die off in September. As soon as this happens, the resting season should commence, during which no more water should be given than is absolutely necessary to keep the bulbs from shrivelling. When they begin to grow, the water supply should be gradually increased. The flowers, when expanded, last in tolerably good condition for nearly three weeks, and those of *P. maculata* for a week longer; while open, they should, of course, be kept dry, otherwise their beauty becomes greatly impaired. Unseasonable resting is one of the greatest causes of failure amongst these lovely little Orchids. *P. maculata* is one of the earliest flowering kinds, and also one of the prettiest. *P. Wallichiana* is a beautiful deep rose-coloured species, that blooms a week or two later than *maculata*, under similar circumstances. *P. lagenaria*, quite a gem in its way, has mauve-coloured sepals and petals, and a white lip faintly tinged or veined with crimson. There are also two other beautiful species, viz., *P. humilis* and *P. Reichenbachiana*, the last of which has a pretty fringed lip. These little Orchids should all be potted in the beginning of November, or when the flowers fade.—W. F.

Second Year Hyacinths.—Is there any mode of treatment by which Hyacinth bulbs may be made to bloom more than once in perfection?—R. W. [We fear not; but, by treating them as follows, a tolerable degree of perfection may be arrived at:—As soon as their beauty of flower is over, we always cut off the flower-stems just below the lowest flower, and for this reason: the Hyacinth and Tulip both seed freely, particularly the latter; if the bulb is forming seed, its strength is wasted in a great measure by that process; whereas, if the flower-stem is cut off, the bulb has nothing to do but to prepare itself with vigour for blossoming in the ensuing year. We pay great attention to the protection of the leaves of both Hyacinths and Tulips, and never allow them to be interfered with until Nature indicates, by the decay of their points, that the bulb is preparing for rest. We then follow a course with both Hyacinths and Tulips which we believe many do not; that is, we take them up before the leaves are quite decayed, and for this reason—we believe that both of them, after the bulbs have attained this period of growth, are only weakened by remaining in the ground, because the offsets are living upon the parent bulb, and, consequently, weakening it for the flower of the following year. If a cultivator wishes for stock, he should let his bulbs remain until the leaves are quite decayed. If he wants his bulbs to flower in beauty again, he should follow the practice above mentioned. When taken up, the bulbs should be removed to a shed sheltered from the sun, but free to the air, and any earth adhering to the fibres or roots should remain for some little time; after two or three days they should be looked over, and the loose earth shaken from them; and, as the leaves decay, they should be occasionally removed. We have generally placed our bulbs at first on the ground, in the tool-shed, and, as they got dry, removed them to an airy shelf. When the leaves are nearly decayed, we place them in very shallow baskets, and allow as much air as practicable to be between each root to harden them, turning them every two or three days. By this treatment, and rubbing off any portion of mould attached to the bottom and sides, they are in a fit state to be placed for the summer in a dry room; and, by a little occasional attention, the rough and outside coat will, by a gentle side-pressure of the thumb, be effectually removed, and exhibit the appearance of the bulb clean, smooth, and in good condition. This latter operation is best performed in the end

The Wild Ipecacuanha (*Asclepias curassavica*).—This makes an excellent summer-flowering greenhouse plant, and well deserves cultivation on that account. It produces seeds freely, and if they are sown in the month of August, and the young plants grown in a stove temperature throughout the winter and spring months they

of August, and at that time remove the remains of such parts of the root of the former year as may not have dropped off previously to this time. It is hardly necessary to state that any bulb in an unsound state, either from appearance of decay, or from having been injured in taking up, should not be put with those intended for future planting.]

BOUVARDIA LEIANTHA.

THE genus *Bouvardia*, named after the astronomer Bouvard, belongs to the great natural family of the Rubiaceæ, which includes the Cinchona plant, the value of whose properties, as a febrifuge, is well-known from the popular name of its product, Quinine. The plant under notice, of which we give a representation of the extremity of one of the branches, with its flowers and leaves, is a native of Guatemala, Central America. It forms a neat shrub of 2 or 3 feet high, branching very much at the top, each branch being terminated, in the flowering season (which lasts from July to November), by a hemispheri-

Bouvardia leiantha.

cal corymb of pretty vermilion-red tubular flowers, which are most effectively relieved by the deep green hue of the leaves. One of the chief merits of this plant is that, in addition to its great intrinsic beauty, it lends itself most readily to cultivation as a room or window plant. A mixture of peat-soil and fibry loam is the compost in which it thrives best; and the plant is very easily propagated by means of cuttings taken from the youngest branches, and struck on a gentle hot-bed.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Bletia (verecunda) Shepherdii.—This is an old and very easily grown Orchid, well worth general culture on account of the copious supply of rich purple blossoms which it furnishes at this season of the year. Its bright purple segments contrast well with the golden-yellow plates on the lip, and, it is well adapted either for button-holes or for bouquets. It is now in bloom at Kew.—B.

Woodwardia radicans Brownii.—This fine Fern was discovered by Mr. Brown in the Island of St. Michael's. Pinnæ and pinnules extensively subdivided, the latter deeply cleft at the terminations, and finishing up the sides of the fronds with tufted branches or crests starting from each other almost at right angles. Terminal crests larger, frequently several inches in width, and composed of almost innumerable small excurrent points. Unlike many other abnormal forms, the peculiarities of this variety are quite apparent in plants not more than 2 inches high. Of this exceptionally distinct and handsome kind, Messrs. Stansfield, Todmorden, possess some good plants.

Oncidium cheiroporum.—This Orchid, which is now being sent out by MM. Thibaut & Keteleer, of Sceaux, is a dwarf caespitose species with small and very flat pseudo-bulbs, each surmounted by a single linear leaf, about 8 inches long and nearly an inch wide. From the base of the pseudo-bulb springs another leaf, from the axil of which issues a flower-stalk about 16 inches long, with numerous lateral branches, each bearing seven or eight flowers, of a fine light-yellow colour, and somewhat resembling a bat in shape. It continues a long time in bloom, and will probably be found capable of culture in a cool-house.—W. M.

EFFECTS OF HEAT ON PLANTS.

THE action of heat on plants has been made the subject of an elaborate series of experiments by M. Blondeau, who has contributed an account of his researches to the *Moniteur Scientifique*. The apparatus used was very simple, consisting of a sheet-iron muffle, through the cover of which passed the stem of a thermometer. The muffle, with water in it, was heated to the required temperature, which was kept constant by a Bunsen burner. To produce low temperatures, ice or a refrigerating mixture was employed. M. Blondeau first endeavoured to ascertain the effects of heat on annual plants, and the temperature necessary to destroy vitality in the various organs. He exposed to a temperature of 122° many kinds of seeds—those of garden vegetables, grain, Acorns, &c.—which were first proved to possess vitality. After remaining an hour at this degree of heat, they had all lost the power of germination. Either the embryo was killed by the heat, or the substances stored up in the seed for its nutrition had undergone changes that rendered them unfit for that purpose. Now it is well known that, when heat does not exceed certain limits, instead of being hurtful to vegetation, it favours it. If seeds are placed in tepid water at a temperature of 68° to 77°, the substances contained in the seed are softened, and become more readily absorbable by the embryo. If the embryo dies at the higher temperature of 122°, it seems probable that heat, raised to this degree, has become a poison, the effect of which has been to paralyse the organs and destroy the irritability of the tissues. It is a confirmation of this view that the vitality of certain organs, and even of the entire plant, is destroyed by the same temperature, while the tissues do not appear to have undergone any appreciable change. For example, the end of the stem of a Balsam plant was subjected to a temperature of 122°, a number of the leaves being thus exposed to the heat, while the rest of the plant was protected by a screen. On removal from the muffle after an hour, the exposed leaves presented nothing peculiar. Examined with the microscope, they showed nothing indicating the least alteration of tissue. Nevertheless, these leaves had been killed, for, after a little while, they became dry and withered. The vitality in the organs of the plant had been destroyed, without the tissues being changed. It might, perhaps, be thought that the effect was due to a rapid evaporation of water contained in the tissues. To settle this point, instead of putting the end of a plant in the muffle, it was simply immersed in water at 122°, and kept there a quarter of an hour. The part thus affected by heat did not continue to vegetate, but withered in a few days; showing that death was due to the direct action of heat, and that evaporation had nothing to do with the result. The entire plant, except the root, was then subjected to the temperature of 122°, the root being kept in earth. The effects were similar. Removed after an hour, it soon faded and the stem became black, as if it had been exposed to a very high temperature. All seemed to indicate that the plant had succumbed to a poison, which had left no trace on the organs by which vitality is manifested. It remained to decide whether the vital force, which can be easily destroyed in the leaves and the stem, presents a greater resistance in the roots. Would heat have the same effect on the organs of nutrition as on those of respiration? To determine this, the pot of earth containing the root of a Balsam was placed in a water-bath; the upper part of the plant being kept out and protected against the heat by a screen. A thermometer was inserted in the earth of the pot; and when the temperature had been raised to 122° the pot was removed and left to itself. At first nothing remarkable occurred, but in a few days the plant gave signs of diminished vigour, and gradually withered and died; proving that the toxic action was as energetic on the roots as on the other parts of plants. Another simple experiment served to determine the limit at which roots begin to lose their vitality. Having taken out of the ground several plants of Balsam, the roots were immersed in water raised to 86° and 104°, and, after a quarter of an hour, were re-planted. The only ones that recovered were those that were heated only to 69°; none of the others took root again. All plants are more or less affected by this agent when it exceeds certain limits. In our gardens, the watering, which is frequently required, serves, not merely to supply water necessary to vegetation, but also to refresh the ground and prevent its attaining a temperature which may become fatal to plants. The absence of heat appears to have the same influence on vegetation as the excess of heat. When the layer of earth in which roots of grain are situated, falls to 25° or 30°, the plant grows yellow, showing a diseased state which, commencing in the roots, gradually spreads up the stem. If a leaf of Balsam, adhering to the stem, be introduced into a glass tube, surrounded with ice (care being taken not to bruise it), and be kept there long enough to be cooled down to the temperature of the glass, it will be killed, and will present the same phenomena as leaves heated up to 122°. Examined with the microscope, it shows no organic change, and yet it is unable to perform its functions. It soon withers, and falls off.

GARDEN DESTROYERS.

GARDEN PESTS.

By THOMAS BAINES.

Cabbage Grub, or Clubbing.

THIS insect often does very great mischief, especially in old gardens, where it is far more numerous than in new soil. The damage it causes is often a serious matter for the gardener, as it destroys almost whole crops, and makes very inconvenient gaps, especially in summer Cauliflowers. When the grubs first attack a crop there is nothing to indicate their presence until the plants begin to turn an unhealthy colour; then they flag in the sun, and in a few days the crop is lost. There is no variety of the Cabbage tribe quite free from these pests, although the different kinds of Winter Kale, as well as Red Cabbage, are more seldom affected than Cauliflowers and summer Cabbages. There are several means employed to lessen their numbers, and to render the ground distasteful to them, such as winter dressing with salt or lime, or a liberal application of wood-ashes; this all assists more or less to reduce their depredations generally, but fails to prevent the most objectionable appearance a crop presents when there are gaps here and there all through it; and in ground that is much infested with the insect, I have found these dressings, which are usually palliative, altogether ineffectual. After employing every means that I could hear recommended, with partial success, it occurred to me that there was no chance but trying to make each plant unpalatable to the grubs. In the spring I procured some newly-burnt lime, which was laid under cover until it became air-slaked. I then took an equal quantity of soot and mixed it with the lime. In planting, the holes were made with the trowel in the usual way; each plant was dropped into its hole, an inch or so of soil put over the roots, a good watering given, then a moderate handful of the soot and lime mixture thrown in each hole, and the remaining soil filled in. The ground where this was tried was an old garden that swarmed with the insects to such an extent that it was impossible to get a crop of either summer Cabbages or Cauliflowers by any means I had previously tried; but in this case I did not lose a plant. When the crop was gathered I examined the old stalks, and the mixture was there in close contact with them, still in sufficient quantity to ward off the attacks of the grubs. No insect either fully matured, or in the early stages of its existence, can bear the presence of soot. From that time—a good many years ago—until the present, I never put out a single plant of any of the Cabbage tribe without their being so treated, and we rarely lose a plant through the grub, unless owing to a careless application of the mixture. In this there is some difficulty, unless there is personal supervision. For instance, even after the clearest directions, a man will sometimes put in the mixture first, and water the plants afterwards. This, as will be seen, washes the stems clean, taking the mixture down into the soil, away from where it is required, and affording no protection to the plants. If carefully applied as described, it is effectual. Where plants are put in by the acre it is some additional labour, more from the number of times the ground has to be gone over in planting than from the mere application of the mixture. I have found that it takes about a third more time than planting in the usual way; but even so it is much more satisfactory than the appearance of broken crops, to say nothing of the loss frequently caused by their total destruction.

Wasps.

The depredations of wasps are principally confined to their attacks upon ripe fruit. For some miles round the outskirts of large towns they never appear in such numbers as they do in purely country districts, where they are not so much molested. It is here that the ravages they commit are the most serious, with some fruits almost defying any means to preserve even a portion of the crop. The Greengage Plum is an especial favourite with them. I have seen them destroy the whole crop produced by numbers of trees, not allowing any to get fit for table; as each fruit began to ripen on one side, the wasps commenced their attack. Pears, Peaches, and Nectarines on the open walls, suffer in like manner. Ripe Grapes are

especially their favourites. When they attack a Vinery, they will quickly destroy the whole crop if left undisturbed. Like the majority of other pests that attack garden produce, they are best nipped in the bud. On fine mild days in early spring, the warmth of the sun brings the queens out, every wasp at this season representing a colony, and every means possible should be employed to destroy all that make their appearance thus early. A small price upon their heads at this season offered to children will prevent the progeny of these queens from ever coming into existence. If it should happen that the weather is unseasonably mild at the end of March and beginning of April, so that it brings the queens out early, the chances are that the wasps are not numerous during the after part of the season, as these early bright days are usually succeeded by sharp frosty nights, which destroy these prematurely-awakened queens. On the other hand, in late springs, they do not so soon make their appearance, and, consequently, escape the effects of the return of cold weather. It is in such seasons that they are the most formidable, in many places defying all means to cope with them, especially out-of-doors. In Vineries several methods are employed for the protection of the fruit, with more or less success. Muslin or thin paper bags, in which to enclose the bunches are often used; but there are several objections to both, especially in the autumn, for, if the bunches are not frequently examined, odd berries begin to mould, which quickly affect the whole bunch. The moving of the covering also destroys the bloom, so indispensable to the appearance of first-class fruit; and it frequently happens that, with all the care that can be given, the wasps will find their way through the bags. By far the most effectual method to adopt is to keep them out of the house altogether. This can be done by the use of the hexagon garden netting, tacked over all the openings where air is admitted: this is sufficiently open to admit all the air required, without the wasps being able to get through; even if the doors are required open, a large piece of the netting can be temporarily hung over the doorways. When they attack choice fruits, such as Peaches, Nectarines, and Apricots, on the open walls, it is necessary not only to adopt means for their destruction, but such also as will attract them from the fruit they are devouring. Every tree bearing fruit on which they are busy at their work of destruction should have three or four wide-mouthed bottles hung in it, half-filled with sweetened beer, or treacle and water; this will attract them from the fruit, and they will also perish in large quantities. Traps may be made as follows:—take a bell or hand-glass, with a small hole in its top, elevate it on half-bricks, place some damaged fruit under it to allure the wasps, then place on the top another glass, tight-fitting in every way; numbers of the insects will ascend through the hole in the top of the under glass into the upper one, from which they cannot find any exit, and soon perish. A number of these traps placed upon the wall coping, as also on the ground at the foot of the trees, will be found effectual, not only for the wasps, but also for the large blue-bottle flies, which generally first attack Peaches, making incisions which are quickly taken advantage of by the wasps. An idea may be formed of the number of wasps existing in some parts of the country, as also of the quantity that may be destroyed when a sufficient number of traps are employed, when I state that I have seen a gallon-pot full of them taken in a single day by the above means. All nests that can be discovered should be destroyed. An offer of 6d. or a 1s. apiece for the nests will be sufficient inducement to bring very great numbers of them in. The best method of taking their nests is, after dark, when the greater portion of the colony are at home, to thrust rags, dipped in gas-tar, into the nests, which set fire to, and when freely ignited close up the hole; not a wasp will escape death. The nests may then be dug out, and the young grubs destroyed. Or 1 oz. of gunpowder mixed with 2 oz. of sulphur, tied up in a paper, may be thrown into the nest, ignited, and the hole closed. Another method is to take an ordinary beer or wine bottle, containing a small quantity of spirits of turpentine, and, at nightfall, when the wasps are quiet in the nest, thrust the neck of the bottle into the entrance, and let it remain for a day or two. The fumes of the turpentine will suffocate all the wasps, and the nest may then be dug out, and the grubs destroyed.

THE FLOWER GARDEN.

FERRARIAS.

THE genus *Ferraria*, named by Burmann in honour of Jean Baptiste Ferrari (an Italian botanist who flourished in the earlier part of the last century), is very nearly allied to the Irises, and contains two or three species which are deserving of some notice at the hands of our cultivators—amateurs or professional. Some time ago, one might occasionally see *F. Pavonia* (better known, perhaps, as *Tigridia Pavonia*) here and there in gardens; but, of late, from our own experience, at least, it has become comparatively rare. The great defect of the *Ferrarias* is, that their flowers are most fugacious, and, although both pretty and singular, they last for so short a time (a few hours only) that we believe this to be the reason why they have, to a great extent, dropped out of cultivation. The flowers, however, notwithstanding their brief period of existence, present such a strange combination of the aspects of the *Stapelias* and the *Orchids*, that even a fleeting acquaintance with them well compensates for the slight trouble involved in the culture of the plants. Our illustration (which represents *F. undulata*)

Ferraria undulata.

will give, to those who are not familiar with these plants, a good idea of their general appearance. This species grows to the height of from 2 to 2½ feet, and has imbricated sword-shaped leaves, like those of an Iris. The flower-stem is furnished with two or three bracts, from the axils of which, as well as from the extremity of the stalk itself, flowers are produced. They are seldom more than two or three in number, and are of a very peculiar reddish-brown colour, with violet reflections, like the shades of certain shot silks. In the centre is a whitish circle, and the margins of the petals are marked with yellow dots on the upper surface, while, underneath, the petals are entirely white. The plants are easy of cultivation in a conservatory or greenhouse, if potted in slightly peaty soil, and well watered during the flowering season. W. M.

A USEFUL BOX FOR CUTTINGS OR SEEDS.

To those who object to shallow earthenware pans for the raising of seeds or cuttings, on account of the needless amount of space they occupy, I recommend boxes made in the following manner. Procure a few slates of the Countess or Lady size; the former are 20 inches by 10 or 18 inches by 10, the latter

16 inches by 8. I use a size between the two, 16 inches by 9. Get some strips of $\frac{1}{2}$ or $\frac{5}{8}$ inch deal, 3 or 4 inches wide. Cut them in lengths to suit the size of the slates. Of these make the sides and ends of your boxes; cut off two extra lengths to go across the bottom, an inch or two from each end; let your slate rest on these to form the bottom, and your box is ready

Box with moveable bottom for Cuttings or Seeds.

for use. In the course of time the lower edge will begin to decay, together with the cross pieces. When that happens, turn the box upside down, after having nailed on two new pieces on what was the top. When you have to remove the seedlings or cuttings, push up the slate from below, and you can remove them without injury. Crocks, Coconut-fibre, or any other material can be used for drainage, and the superfluous water will readily escape round the edge of the slate. These boxes will, of course, look better and last longer if they are painted; but that operation had perhaps be better deferred till after they have been used one season and have become thoroughly dry after use. One season will have had no injurious effect upon them, and if, as often happens, the wood used is not thoroughly seasoned, it is better on that account to defer painting to the autumn. It would be well at that time to remove the bottom pieces, and paint with at least two coats before they are replaced. Boxes so constructed can be used directly they are made, and, if painted in the autumn, will be ready for use again the following spring. B. S.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Crustaceous Group.

Saxifraga Aizoon.—The ever-living Saxifrage, as the literal translation of the name would imply, stands, as I stated last week, as the typical representative of several forms that we have long dignified by the title of species, and here I am disposed to agree with Engler—not exactly, however, to merge them all as synonyms, but to give them what appears to be their true position as distinct varieties. Before, however, we deal with them, I must say a few words as to the parent itself. Of compact and dense habit of growth, it presents a mass of small rosettes, whose leaves are bluntly obovate and slightly incurved; the margins, as in all its varieties, lined with small cartilaginous serratures, and dotted with a dense line of crustaceous markings. It produces its flower-stems in abundance, rising to a height of 9 inches. The flowers are whitish, and grouped in somewhat dense cymes. It enjoys, perhaps, the widest geographical range of all the Saxifrages, being found in all the Alpine districts of mid and south Europe, extending northward to Lapland, and even Spitzbergen, and westward through Greenland into North America; with such a wide range it may well claim for its progeny a marked amount of divergence from the parent form.

S. Aizoon var. intacta.—Possessing the dense habit of the old species, and differing very little, if anything, in the flowers, its claim to recognition rests on the much narrower and more erect leaves, the marginal markings being less conspicuous, and the general green of the leaf having a greyer tint during summer, and in the autumn assuming a chocolate-brown colour, which it retains during the winter.

S. Aizoon minor.—This, hitherto called *S. intacta* minor, and of which latter no doubt it is a dense and compact form, I have recognised as a variety of the more remote parental type, because I think it unwise to increase the number of names by the introduction of sub-varieties. Possessing, as it does, the narrow foliage of *intacta*, so densely are its little rosettes arranged that they quite lose their individuality, and scarcely a pin's point can be inserted in the dwarf cushion-like mass that it forms without damaging a leaf. Hence it has been appropriated by the flower gardener, as constituting an admirable ground-work of peculiar grey glaucous green, on which to exhibit some of his more tender pets; it has a further advantage to recommend it for this purpose, that it is a shy bloomer, and hence

does not assume the somewhat ragged appearance that all those which bloom freely do immediately after the flowering season is over. I have seen it used as a substitute for the *Selaginella* in those geometrical glass arrangements for the dinner-table which are now amongst the waning fashions of the day. The effect was good as a matter of variety, and, placed in such a conspicuous position, it would be sure to attract close attention, and its many, though minute, beauties would manifest themselves that otherwise might be passed over unobserved.

S. Aizoon recta.—This is, unquestionably, the same as the variety called *gracilis*, by Engler, and were it not so well known by the former, I should willingly adopt the new name, as it conveys a correct idea of the habit of the plant. It differs chiefly from the typical form in the arrangement of the rosettes being far more lax, each one having space for perfect development, and each sending out several slender surculose runners, which, from their extremities, ultimately develop fresh rosettes. Its flowers are smaller and less dense in their arrangement, and I have found it retain its character very constant from seed. It is met with abundantly in the Alps and in the Tyrol, where, from its lax habit of growth, it freely intermingles with the adjacent forms of vegetation, instead of monopolising large patches to itself, as the case with the foregoing.

S. Aizoon major.—This I take to be the best title under which to group three hitherto recognised species, namely, *S. Malyi*, *S. elatior*, and *S. robusta*, they are in truth nothing more than large forms of the old species.

S. Aizoon germanica is recognised by Engler under the title of *orientalis*. It differs from all the foregoing varieties, in the fact of having longer leaves, broadest at the base and gradually tapering to the point. It is not, with me, a free-grower, nor have I ever seen it bloom; I have a strong suspicion that it would be more at home as a variety of *S. pectinata*, it lacks, however, the bright crustaceous markings of that species, and is, very possibly a hybrid production.

S. crustata.—A well-known beautiful and constant species. Was looked upon by Sternberg as a lesser variety of *longifolia*. It forms a dense mass of hard narrow sulcate leaves, short and reflexed, and margined with very distinct markings, that retain their brightness both winter and summer. It is neither a very free grower nor an abundant bloomer; its rosettes are irregular, and are clustered together on a very short axis, they are not readily divided, nor do they root very freely; its floral axis is 6 to 8 inches long and its broadly ovate petals, as well as the dense arrangement of the blooms, give it a more than usually showy character in this respect. It is found wild at high altitudes on the Tyrolean Alps, and the Carpathéan and Carniolian mountains.

S. crustata hybrida.—Originated with me many years ago as a seedling from the true species, but presents, in its freer growth, broader and more upright leaves, unmistakeable evidence of a close relationship to the *infacta* var. of *Aizoon*. Singular enough, all the seedlings produced by a series of sowings extending over some years, show the same hybrid character, nor have I ever found a single seedling represent the true reflexed character of the leaves in the original species, even when the parent plant has been completely isolated during the flowering process. It is, however, quite possible that the true plants, as raised from the seed, will be of very slow growth, and hence they become smothered amid their stronger-growing brethren, illustrating that process of natural selection whereby the weaker succumbs to the stronger. Be this as it may, it is a variety well worthy of culture, and grows freely and rapidly in any light garden soil.

S. carinthiaca.—Though I have not had it sufficiently long in cultivation to speak decidedly thereon, it appears to claim a much closer relationship to *crustata* than to *Aizoon*, of which Engler makes it a variety; so I conclude that his plant and the one we have under the above name in cultivation are quite distinct. Its appearance is exactly that of *crustata*, with shorter leaves, smoother at the margins, and very slightly reflexed. Not having seen it in bloom, the remarks I make may be obviously open to modification.

S. lantoscana, recognised by Boissier, and figured by him as a distinct species, is, as I before stated, looked upon by Engler as a variety of *lingulata*; but failing, as I do, to see the grounds of relationship, I adopt Boissier's dictum in preference. It is a somewhat nondescript plant in appearance, with the leaves irregular in shape, and "zig-zagged"—if I may coin a word—across one another. The rosette arrangement, as I have grown it, is altogether at a discount; the leaves are narrow and blunt at the points, or not unfrequently obliquely cut, the extreme end being generally recurved in a hook-like fashion. I have not seen it bloom, nor do I find any special description of its flowers. It is of equally slow growth with the true *crustata*, and derives its name from the valley of Lantosca,

in the Maritime Alps, which locality appears to be its present only known habitat.

S. cochlearis, of Reichenbach, like the foregoing species, is called by Engler a variety of *lingulata*; but, surely, it possesses such distinct character, in both growth, foliage, and bloom, that there need be no hesitation in endorsing Reichenbach's nomenclature. Here we have a dense compact-growing plant, with leaves of a dark green, beautifully margined with a crustaceous line, rather than dots, and not unfrequently suffused with white over the entire surface, as though Nature had let her paint-brush fall and smeared her delicate handiwork; each leaf is about 1 inch long, the lower portion linear, the upper part expanding into a broad blunt-pointed blade, slightly recurved at the margins; the flower-stem is covered with dark glandular hairs; the flowers themselves are white, the lower portion of each petal being dotted with crimson dots. To my mind, there is no species in the whole crustaceous group that claims its right to specific distinction more thoroughly than does this. To my floricultural friends, I may remark that it promises to be one of the most valuable for decorative purposes that we possess. I believe we are indebted to Mr. Maw for its introduction into cultivation in this country, as the result of one of his botanical rambles in the Maritime Alps.

S. Rocheliana, one of Sternberg's old species, is a dwarf compact-growing plant, with broadish little leaves, horizontally expanded, terminated by a somewhat acute point, and channelled on the upper surface, each leaf having from three to five crustaceous spots at the apex; the flower-stalks are erect, about 3 inches high, terminated by two or three flowers of a yellowish-white, the whole stalk covered with green glandular hairs. It is the very earliest bloomer of all the section, flowering, as it does, in February; but such a liking have the slugs to its early-produced petals that, unless it be closely watched for these depredators, it might readily be taken for an apetalous plant, so scientifically do they excise the white petals. This species does not appear, by any authentic records we have, to enjoy a very wide distribution, the Carpathéan and Roumelian mountains being its only present known habitats. It grows freely under rock or pot culture, and, like all the smaller forms of this group, appears to like a fair admixture of peat in the soil in which it is planted.

S. coriophylla, of Grisebach, is looked upon by Engler as only a variety of the former species. The general contour of the plant is, however, perfectly distinct, and this distinction is abundantly confirmed on a closer examination. Its rosettes are considerably elongated and less dense in their arrangement, as well as twice the size of *Rocheliana*; its leaves are long, blunt or rounded at the point, and gradually taper to the base, added to which, they are slightly incurved, smooth at the margin, and lined with a few widely separated small dots. The inflorescence in a young state is always bent downwards—not erect—the flowers themselves are large, the largest, in fact, of all the section, produced in compact heads of six or seven in number, and supported upon a leafy stalk about 6 inches high—the whole, including the calyxes, are covered with green glandular hairs; added to which, the flowers are a pure white, and are produced in the month of April. This brief description when compared with that of *Rocheliana* given above, will indicate at once how distinct the two plants are, as well in outward appearance as in botanical character. It is a native of Bosnia and Albania, and occurs at a considerable mountain elevation. With me, though I have grown it successfully for many years in large pans, as well as in the rockery last season, every plant appeared simultaneously to turn brown, with an evidently sickly appearance; some I left to their fate, some I shook out, re-potted, and divided, but the result was in every case alike; this spring, as I now write, I find they are all dead; fortunately, I raised a lot of seedlings two years ago, and, although they are yet small, they are in good health, and everyone as true to the parental character as can possibly be, thus, confirming its specific distinction.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Primula japonica.—Will this grow from seed and come to perfection in the same year? and is it quite hardy, as advertised by Mr. Bull in *THE GARDEN*?—TWEED. [The seeds of this plant are somewhat capricious as regards vegetating. Sometimes they come up in a short time after having been sown, at other times the seed lies dormant for many months. Plants that come up during the spring, or early summer, will make flowering plants the spring following. The plant has stood the winters we have had since its introduction. How it would fare in such a winter as 1860-61, remains to be proved.—ED.]

Phygelius capensis.—This really pretty plant ought to be more generally grown than it is; although a native of Southern Africa, it is perfectly hardy in most situations, and may be readily increased by means of cuttings, or seeds, which ripen freely. A plant of it put out in the open border here (Derby) some two or three years ago, now covers about a square yard, and has been much admired during the summer and autumn months. It blooms most profusely until cut off by frost. In spring, the dead tops, like those of outdoor *Fuchsias* may be cut down before it starts into growth.—J. W. MORLEY.

THE FRUIT GARDEN.

THE FIG APPLE.

THIS interesting little Apple is said to be that which was eaten by Eve, and, if so, singularity of form must have had more attraction for her than beauty. The following is a description of it, made from fruit grown at Merriott. Figue d'Hiver (D'Adam, Petalless, Sans Fleurir, Sans Pepins, à Trochets), third size, second quality, January to March, conical or pyriform, and drawn in or twisted at the base; skin, yellowish, dotted with russet, and tinged with carmine on the sunny side; stalk, about 1 inch long, set obliquely in a shallow cavity; eye, large and open, placed in a very wide and deep basin; flesh, whitish, firm, and crisp. This variety is always seedless, and Poiteu, in his "Pomologie Française," says the petals are so small as to escape general observation, but that is not the case here, as they are pretty large, and tinted with rose. It is probable that this is the Apple described by Pliny under the name of Spadonium, because it is seedless, and, as no other Apple has ever yet, as far as I know, been found uniformly sterile, it is only reasonable to suppose that this variety is the fruit to which he alludes; if so, it must have come down to us through a long series of years, and shows how tenaciously we hold on to our old fruits, even when they have been immeasurably surpassed by finer sorts. There is another Fig Apple described by

The Fig Apple.

Bauhin, which must be entirely different from this one, as he would, doubtless, have taken notice of its abnormal characteristics, such as the absence of stamens and seeds. It is very possible that his Figue Apple was what we now grow as Figue d'Été or Letire. To prevent mistakes, we grow an Apple here called Adam's, but it is an American variety, and entirely different from the Figue d'Hiver.

J. SCOTT.

Merriott, Crewkerne, Somersetshire.

SPRING PROTECTION OF FRUIT TREES.

THIS is an important subject at this season of the year, and one which will require the attention of all horticulturists who are interested in saving their fruit crops. We have experienced an exceptionally mild winter; and this, by bringing on the fruit or blossom-buds somewhat prematurely, renders them still more liable to suffer from late spring frosts than would be the case after an early and severe winter. While the buds are safely encased in their closely-imbricated bracts, no amount of frost or sleet will hurt them; but, after a mild winter, our fruit crops almost invariably suffer. In a word, it is not a long period of frost and wintery storms that does the mischief; but the mild open sunny weather which often occurs during December, January, and February, and then the cold wet winds or sharp "catches," which are peculiar to March, April, and even May. In a variable climate like our own, we must either pay considerable attention to the protec-

tion of our fruit crops, more especially to Peaches, Pears, and Apricots on walls, or run the risk of losing a season's produce. As a rule, our climate is not a severe one; but sudden fluctuations in temperature more than counteract this advantage, and leave us actually worse off with regard to our fruit crops than those who experience far more severe, but regular, winter seasons. The French Peach-growers, many of whom depend on the sale of their produce for a livelihood, carry spring protection to its utmost limit, and understand the principles of shelter, on which success depends, far better than the majority of our horticulturists at home. The best of all spring protectors for our climate is, undoubtedly, a glass-case, wherein the trees are dry, and where a crop is almost a certainty; still, there are many who grow a few choice fruit trees who do not care to go to the expense of a glass-case, and for these there is nothing less expensive than a coping-board, 9 inches or 1 foot broad, with tiffany or Shaw's Hexagon netting hung in front during the night, and even all day when bright sunshine succeeds a severe frost. It is astonishing what a little protection in the way of a fold or two of any thin fabric will effect, not only in protecting the tender blossoms from sleet, hail, or cold rains, but, also, in preventing, to a great extent, the radiation of heat absorbed by the walls themselves during fine and sunny weather. In some of our best gardens, canvas blinds, properly fixed on rollers beneath the wall coping, are employed; and this is a good plan to adopt, as such a provision effects a saving both in time, labour, and material. Broad or projecting copings are specially valuable, and in the Peach-gardens at Montreuil, near Paris, narrow hurdles of reeds are used for this purpose; these project about 2 feet from the top of the wall, and are upheld by slanting supports fixed in the masonry at regular distances; and to prevent them from being blown off by winds, each is securely tied in its place. These are invaluable, as the trees are kept dry, and when that is the case, a sharp frost does but little harm. The spring protection of our wall-fruits has of late years met with considerable attention, and various glazed protectors have been brought into public notice, which doubtless answer their purpose admirably when expense is not an object, but, when these cannot be afforded, other less expensive contrivances must be resorted to. Where other means are not at hand, an excellent shelter for wall trees may be constructed by any intelligent labourer, by making frames of deal or pine, say 10 or 12 feet square, according to the height of the wall; diagonal spars will hold them tightly together, and transverse bars, 18 inches or two feet apart, should be tacked on, through which Fir boughs may be drawn to afford protection, and at the same time allow the ingress of sufficient light, and a free circulation of air. These frames may be fixed against the coping and can be allowed to remain for weeks together in cold frost and rains. It is always advisable to close up each end of these frames where many are placed together, otherwise a cold current of air will be always rushing between the screen and the wall. Bright sunshine after a sharp black frost is more fatal than anything else to fruit buds, and even where the buds are frosted they may often be saved by syringing them with cold water and shading them early in the morning before the sun shines on them. In all cases, the protecting material should project clear from the trees, at least 9 or 10 inches, and the lighter and drier the material used, the better will it act as a protector.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

A Queensland Fig Tree.—Mr. Walter Hill, the Government botanist in Queensland, reports to the authorities there that, while cutting a given line on the banks of the River Johnstone, for the purpose of examining the land, an enormous Fig tree stood in the way, far exceeding in stoutness and grandeur the renowned forest giants of California and Victoria. Three feet from the ground it measured 150 feet in circumference; at 55 feet, where it sent forth giant branches, the stem was nearly 80 feet in circumference.

Plum Culture in Scotland.—The Damson is a fruit which used to be very much cultivated for the market in many parts of Scotland. About thirty-five or forty years ago I saw in some districts of Ayrshire, trees literally bent down with fruit. Such a sight I have not seen in Scotland, except in Ross-shire, for many years; but even there I am informed that heavy crops are only partial. The Ross-shire climate has always been considered one of the best north of the Tweed for ripening fruit, both wall and standard. Of recent years, a considerable extent of Plum orchards has been formed in many parts of the west coast district, where the climate seems well suited for their growth; but instead of Damsons, plants of the Victoria Plum are most in demand for the purpose of planting.—JAMES McNAB.

A HOLIDAY TOUR.

By THE EDITOR.

PUBLIC GARDENS AT LYONS.

ONE might here, at Lyons, far south of Paris, expect a fairer climate, but it is not so. Standing on the high banks over the Rhone, and, looking north-eastwards, what seems an angular snowy cloud is seen, clear, but far away, and one is surprised to hear it called Mont Blanc. From near its feet, and far away across the eastern sky, stretches a wall of whitened mountain-crests, pale and solemn-looking as a distant fleet of icebergs. This is an outlying line of the Alps, whence comes the icy breath which gives the fair city on the Rhone a less favourable clime than that of Paris. Hence it is by no means so interesting from a gardening point of view, but we may, nevertheless, find something worth seeing in the public garden or park. France, in the present generation, has witnessed many improvements, but in no way made more progress than in the matter of public gardens. The sunny street, with its fresh air and green trees, is not a greater advance on the narrow, malodorous and darkened alley it replaced, than the Parc de la Tête d'Or, at Lyons, on such old botanic gardens as those which exist at Angers, Geneva, Milan, and other continental cities. The old botanists too often regarded the garden as a sort of supplement to their collection of dried plants; and, as huge labels, with formidable names, straight walks, clipped shrubs, trees of many kinds and sizes, planted as thickly as Currant bushes, and all cut into the same size, to make them fit into narrow beds, suited to whatever scheme of classification was the mode at the time, were among the most graceful features of these gardens, it was, perhaps a relief to turn to the dried herbs now and then for a change. The true idea that any place, worthy the name of a garden, should show us, as much as may be in one spot, the majesty of the woods, and the thousand infinite graces of vegetation, is gradually finding expression in the Parc de la Tête d'Or, as in many other public gardens in Europe and America. Although called a "park," it is really a garden of some 250 acres, and combines in one establishment the French plan of a botanic garden in all its parts, a zoological garden, a school of sylviculture or *dendrologie*, a large nursery for the supply of the town squares, &c., a very extensive and richly-filled set of Palm and hot-houses, and goodness knows how much besides one fails to see for want of some official printed guide to its contents. In the maze of subjects, I had almost gone away without knowing that there is here a collection of all the Roses cultivated at the present day, a collection of nearly 1,500 kinds, among them being those rare Provence and other Roses of bygone days, so difficult to obtain now. Any private individual who undertook to form a similar collection would probably be laughed at for his pains, but it is, nevertheless, a capital feature in this garden, and one for which many a Rose lover will be grateful. With narrow-minded exclusiveness, botanists have hitherto virtually shut out varieties from the botanic gardens, countenancing or spreading the erroneous notion that such are not as much the production of nature as anything else, so that, in a severely orthodox botanic garden, no such collection of Roses would have a chance; on the other hand, among the cultivators, everybody advocates the culture of the very best only, and the amateur takes the hint and writes to us for the "names of the best dozen Roses!" a distressingly concise list, considering what a host of fair and variously-hued flowers own the name of Rose. Therefore, it would be well if, in every country, there were formed in a public garden such a collection. It would conserve for us the beauties of the past, and permit of our fairly judging of the value of contemporary ones by comparing them with living examples of their predecessors. Few Roses disappear from our gardens from want of merit; they are crowded out by the "swells" of the day, and if growers only strive as to who shall array these most gorgeously, there is more important work left undone. A very interesting classification of Roses, by the way, would be by the period, so to say—the Roses of Shakespeare and Parkinson, of Queen Anne, of our own day, and so on, each in a separate group. The notion may be worth the attention of some gentleman who has won every prize he cares about in the great strife of modern Rose-showing.

In various parts of the Lyons garden there are immense beds and groups of Roses (on their own roots, or grafted low on the seedling Briar), and pegged and pruned down close to the ground. Standards are in effect abolished; this is as it should be. There is no plant so vilely disfigured as the Rose; as M. Jean Sisley, the well-known horticulturist (to whom I am indebted for much friendly guidance hereabouts), remarked, "a Rose on a standard is like a bouquet on a broomstick!" Rose-growers, of tall and mighty frame, like Mr. Hole, no doubt find it convenient to have their competition blooms worked high on tall standards near the eye; but then, show Roses, as everybody knows, more frequently embellish the kitchen-garden or nursery-bed, than the lawn; whereas, the uncalled-for standard disfigures half the gardens in the land. So fully is this felt, if not expressed, even by the stiffest and most prosaic landscape-gardeners, that they speak of the Rosery as a doleful object, when not in bloom, and counsel that every effort should be made to keep it out of sight! Now, any such effect is wholly the result of our management of the plant, which, even in foliage, is superior to nine-tenths of the bushes of any clime, and which only requires to be tastefully arranged in our gardens to improve their aspect enormously. To this end much has to be done, and, previously, several widely-spread ideas have to be plucked up by the roots, viz., that the standard is in any sense necessary or desirable; that the Rose-garden should be an obscure and isolated division of the garden, with all its wealth of beauty lost to the garden-landscape generally; that Roses should be in beds to themselves, in lonely glory, with nothing but dark earth for a carpet beneath their naked stems, and neither Lily nor Gladiolus, fragrant herb nor graceful foliage, other than their own, clustering beneath or mingling in sweet association with them.

Fruit and Other Trees.

A school of sylviculture is a happy idea. If such schools were founded in each important section of every civilised country, gardens would, probably, soon assume a greatly improved aspect. Every traveller knows that, so far as cultivated regions are concerned, England is the most beautiful of countries. This is, to a very great extent, owing to her trees, long allowed to spread their branches in peace, and never, it is to be hoped, fated to boil the soldier's pot. When one considers how very little knowledge of trees there is throughout the land, a vision rises as to how much more picturesque and beautiful even England might be made, if a fair knowledge of the many trees that grow with us were common among all classes interested in gardens. This, in any real sense, can only be attained in a large garden, with plenty of room for every kind to attain full size, and to be arranged in an effective manner. Here the collection was made, regardless of expense and trouble; numbers of trees are planted by the sides of the drive, and have sufficient space for fair development, but not enough for picturesque and varied grouping. Up to the present time, no arboretum we have seen has been designed with anything like a sufficiently broad idea of the subject; in fact it is only such parks as Richmond, the Fairfield, at Philadelphia, and the Bois de Boulogne, at Paris, that offer sites on which to form arboreta worthy of national aims. No attempt has been made to plant any such large parks as tree-conservatories, specially designed to show in due time the full beauty and expression of every obtainable tree worthy of culture. Some precious specimen Conifers, such as Araucarias, were brought from England to this park when formed, but of this tree, and many others long supposed hardy here, the frosts made a clean sweep during the first week of December 1870, just in the midst of the war, and when the frozen plain formed the bed of many a dying soldier. Whole colonies of Deodar, Atlas, and Lebanon Cedars were killed outright, and, almost without exception, all the evergreen trees and shrubs in the garden, including Hollies, Aucubas, Euonymus, and even the Colchic Laurel, generally supposed to be so hardy in England, perished. So much for the influence of these picturesque neighbours the Alps. The city of Lyons, like others in France, has its promenades, well-planted as usual with the Plane, which no cold here seems to touch, and sometimes with Acacia. Some thirty-five years ago, a municipal administrator of this city

VIEW IN THE PUBLIC GARDENS AT LYONS.

distinguished himself greatly in connection with trees. He fancied they were bad for the health, and had all in the city cut down! His name—its deserves remembrance—was Terme. Notwithstanding the destructive cold above alluded to, curiously enough, the evergreen *Magnolia grandiflora* thrives as a standard here and flowers well, though not in such glossy health as it is in Touraine and Anjou. All the Vines about here were killed to the ground or outright by the frost of 1870, so that the growers did not gather a crop for three years. This, one would think worse for them than a visit from the Prussians; but, as usual among this Phoenix-like people, they always quickly rise from their misfortunes. It is a poor country for fruit trees around Lyons, nevertheless, there is a "school of fruit-culture" in the public gardens, calculated to be useful to the natives. The many modes of Vine-culture shown in it, are, of course, of little interest to us, who grow the vine in a wholly different manner and for other purposes; but, an experiment lately carried out as regards the colour of the surfaces on which to train fruit trees is of interest to all. It has long been held that a black surface is the best for ripening fruit. But, more recently, people in this country began to enquire if the colour which absorbed most heat (black) was the one which most favoured fruit-culture against walls. Experiments led to the conclusion, that the surface which reflected heat most (white) was decidedly the best. Here, M. Denis, the chief of the botanical department, tested the question, by covering a considerable portion of the ground beneath Vines with white stones, and another portion with those of a dark-bluish hue. There was a difference in sun-heat of nearly 4° in favour of the white stones at a few inches from the surface, that is to say, at about the distance at which trees are usually trained. This, surely, is a very important fact for all those who have to cultivate fruit trees in a cold climate like ours. There are some modes of training here carried out with a view of resisting high winds which may be worth noticing. Repeated disappointment has arisen in France from having lost fine crops of Pears by wind dashing the crop from the pyramidal trees. The espalier mode of training counteracts this effectively, but there are other good ways and simpler ones. One is the winged pyramid, that is to say, a pyramidal tree with all the branches trained into four, five, or six vertical lines; the branches being exactly one above the other, it is easy to support all firmly from a central point at the apex of the tree and a stake below each wing. This, however, cannot be explained to all without the aid of illustrations, though the form is as easy to make as the common pyramid. Other forms, including the Quenouille, not uncommon in our own gardens, have the branches inter-grafted, so that, growing firmly together, the fruit is not shaken off by the highest wind. It should be observed that these trained trees, on which the fruit, being well thinned and cultivated, is large, require to be more carefully looked after in the above respect than standards, and probably the winds are more destructive than with ourselves, who do not suffer so much in this way. The nurseries round Lyons are small, the market-gardens of no particular merit, and the fruit and vegetable markets of little interest.

HISTORICAL NOTES ON FRUIT TREES.

THE investigation of the origin and introduction of the vegetable productions raised for the use of man, is not only an interesting study in a critical, historical, or geographical point of view, but it may be applied to practical use by the cultivator. In showing how very few of these plants are to be met with naturally in the state in which we grow them, and how, by careful and persevering cultivation, their natural properties have been modified, so as to suit the purposes they are applied to, a stimulus is given to our exertions in the still further improvement of those already known, as well as for the introduction and conversion of new species or varieties to the use of man. At the same time, the knowledge of the readiness with which, in some instances, a worthless weed has been changed into a valuable esculent, and of the lengthened period which has, at other times, been required to effect the conversion, may often suggest to us the *modus operandi* to be attempted on future occasions. But this inquiry is often attended with no small difficulty. However readily we may trace the process by which our European Cabbages and Carrots, or Apples and Pears, have been received into our gardens

and orchards, and there made to produce the luxuriant vegetables and fruits of modern days; however authentic may be the records of the introduction of the tobacco, the potato, and other additions to our esculent, economical, or ornamental plants, since the discovery of America, and the invention of printing, it is a very different matter to trace, with any great degree of plausibility, the origin of the majority of the Cerealia and fruits of more ancient cultivation, and which still supply so important a part of our agricultural and horticultural productions. Tradition ascribes "the East" as the source from whence many of them sprung, and so much is this relied upon that in all cases where a plant, known to have been cultivated in early ages, cannot now be found growing wild, there is a natural tendency to assign as its probable native station some unknown district among the mountains of Central Asia. It is, indeed, probable, that the populous herbivorous nations which early occupied the warmer climates of that Continent, had become cultivators for ages before the wilder and more carnivorous hordes which wander over the colder regions of Europe, and that civilisation, as it spread from the former over the latter, carried with it the more useful Cerealia and fruits then known. But all were already in a state of cultivation, that is, more or less modified by human labour and skill. It seldom has occurred in modern days, still less is it likely to have happened in early ages, that a wild plant has been brought from a distant country to be grown in our own, for the use of man. The conversion must have been gradual, and generally, if not universally in the district where the species was indigenous. Wherever, therefore, the origin of a plant, cultivated in a given country, is involved in doubt, all inquiries tending to clear up that doubt, must resolve into the following queries:—1. When was it first known to have been there cultivated? 2. In what countries, if any, was it previously cultivated, and, if so, when and how could it have been from thence transported? 3. What are the plants indigenous to the region where it was first made use of, which could have been the wild origin of the cultivated varieties? The answers to the first two questions may be derived from actual record, or from collateral historical evidence. But, in early ages, agricultural and horticultural nomenclature was exceedingly vague, and the allusion to vegetable productions is often so slight in ancient works, that it requires very great critical acumen to form any plausible opinion as to the identity of the plants mentioned. The conclusions come to require, moreover, to be constantly checked by a judicious study as well of geographical botany and local floras, as of the general principles of vegetable physiology as applied to horticultural and agricultural metamorphosis; and these geographical and physiological studies can alone supply the answers to the third of our queries.

The Pear (*Pyrus communis*) and Apple (*Pyrus Malus*) are found in their wild state in the mountain woods of the greater part of Europe, and from these indigenous species have been raised the whole of our orchard and garden varieties. Their amelioration by cultivation, and the perpetuation of varieties by grafting, have been celebrated by poets from the time of Ovid, and continue to the present day. Pliny enumerates thirty-nine different Pears known to the Romans, several of them being also mentioned by Virgil, Cato, Columella, Juvenal, Macrobius, &c. Fée has endeavoured to identify some of them with modern French varieties, and Galesio with Italian ones, as in the following examples:—

PLINIAN NAMES.	SUPPOSED CORRESPONDING MODERN NAMES.
Amerina serotina	San Tommaso.
Lactea	Perle or Blanquette.
Dolabelliana	Winter Bon-Chrétien.
Falerna succosa	Bergamot.
Favoriana rubra	Large Muscat.
Superba parva	Little Muscat.
Hordearia	Common Muscat.
Mustea	A variety of Bon-Chrétien.
Picena or picentina	Spina.
Pompeiana mammosa	Campana.
Viridis	Spadona vernina, considered by Galesio as a most ancient Italian Pear.
Myrapia	Guignoline.
Volema	Another Bon-Chrétien.

In Tuscany, under the Medici, we find, in a manuscript list by Micheli of the fruits served up in the course of the year at the table of the Grand Duke Cosmo III., an enumeration of two hundred and nine different varieties of Pears, and another manuscript of that time raises the number to two hundred and thirty two. Among them, grafts of the Dorice Pear of Portugal were introduced by the same Grand Duke, at a cost of one hundred golden doubloons, whence it received the name of Pera cento doppie, by which it is still known, as well as by that of the Ducal Pear.

The Cherry.—We fully concur with Prof. Targioni in his conviction that the wild Cherry (*Prunus Cerasus*), common in the woods of Italy and other parts of Europe and Asia, is the mother plant of all

the kinds of that fruit now in cultivation, in opposition to many modern botanists, who follow De Candolle in distinguishing four species, *Cerasus avium*, *C. duracina*, *C. Juliana*, and *C. caproniana*, or even go far beyond him in their multiplication. The species is also evidently indigenous, notwithstanding Pliny's statement that there were no Cherries in Italy, before the victory obtained over Mithridates by Lucullus, who was the first to bring Cherries to Rome in the year of Rome 680, and that, within one hundred and twenty years after that, they were spread over the empire as far as Britain. This statement gave rise to the tale that Cherries came originally from Cerasus, a town in Pontus, and were therefore called Cerasus by the Latins. Lucullus may, however, have first imported the cultivated varieties, which the Romans may not have recognised as identical with the wild Cherry. In Greece, Cherries were certainly known long before his time, for Diphilus Siphnius, according to Athenæus, mentions them under the government of Lysimachus, one of the dukes of Alexander the Great.

The Plum.—Our garden Plums appear, from the investigations of our Indian botanists, to be varieties produced by long cultivation of the *Prunus insititia*, a species common in the mountains of Asia, from the Caucasus to the Eastern Himalaya, but which we have no authentic evidence of being a native of Europe. In all the more accurate European floras, the *P. domestica* and *insititia* are either omitted, or inserted as doubtful natives or escaped from cultivation; or, if in some instances positive native stations are given for the *P. insititia*, it is generally some variety of the *P. spinosa* that has been mistaken for it. Several varieties of the garden Plum were introduced by the ancient Romans from the East, as we are informed by Pliny, since the days of Cato, who was born 232 years before the Christian era.

The Apricot.—Pliny, as well as Linnæus and most modern botanists, includes amongst Plums the Apricot (*Prunus armeniaca*), a tree most extensively cultivated, and which sows itself very readily in cultivated grounds over South-eastern Europe, Western Asia, and East India, but its native country is very uncertain. The ancients called it *Armeniaca*, as having been brought from Armenia into Italy, where it is not indigenous; also *Præcoca*, *Præcoqua*, and *Præcocco*; and under one or other of these names it is mentioned by Dioscorides, by Galen, by Columella (who is the first who speaks of its cultivation), by Pliny (who, about ten years after Columella, asserts that it had been introduced into Rome about thirty years), by Martial, &c. Democritus and Diophanes give it the name of *Bericocca*, analogous to the Arabian *Berkac* and *Berikhach*, the probable origin of the Italian names of *Bacocca*, *Albicocca*, and even, according to Cesalpin, *Baracocca*; and, lastly, Paolo Egineta, according to Matthioli, has spoken of these fruits under the name of *Doracia*. Although some of these names, even in modern times, have been occasionally misapplied to a variety of Peach, yet they all properly designate the Apricot, and show that that fruit was known in very remote times. Having never been much appreciated, except for its odour, there was not in former days any great propagation of varieties of it. Micheli, however, under the Medici, enumerates thirteen among the fruits cultivated for the table of Cosmo III.

The Peach (*Amygdalus persica*) is, according to the common opinion, of Persian origin. Diodorus Siculus says that it was carried from Persia into Egypt during the time that Cambyses ruled over that country. It is supposed to have been transported from thence into Greece, and, after a lapse of time into Italy, where it only began to be known about twenty years before the birth of Pliny, that is, about seven years before the Christian era, and it appears that Columella was the first to treat of its cultivation there. According to Nicander it was brought to Greece by the agency of Perseus from Cepheia, a locality affirmed by some to have been in Persia, by others in Æthiopia or in Chaldæa. The Peach is also spoken of by Theophrastus, Dioscorides, and other Greek writers. We must, therefore, conclude that this fruit was well-known in the East very long before its introduction into Italy. Many ancient writers, including Athenæus and Pliny, and more recent ones, as, for instance, Marcellus Virgilius, in his "Commentaries on Dioscorides," confound the Peach with the *Persea*, a fruit the identity of which is uncertain, some supposing it to be a *Cordia*, others a *Balanites*. Macrobius again confounds the Peach with the *Persicum* of Senevius, which is the Walnut, and with that of Cloatius, which is the Citron; all fruits resembling the Peach in nothing but in the name, a clear proof that it cannot have been in their days by any means a common fruit. How few were the varieties of Peach known to the ancients appears from Dioscorides, who only names two, from Pliny who enumerates five, and Palladius four only, giving, at the same time, accurate information on the mode of cultivating them. Although all the evidence collected by Professor Targioni tends to show that the Peach was, originally, brought from Persia, and he, therefore, does not consider it necessary to proceed further with the investigation; yet, no traveller whom we can rely

upon, has ever found it growing really wild there or anywhere else. We are left in doubt whether its native stations remain yet to be discovered, or whether its original wild type must be sought for in some species of *Amygdalus* known to be indigenous in the East. It has been more than once suggested that this original parent is no other than the common Almond, a conjecture founded, perhaps, on the similarity in the leaves, and in the perforations of the endocarp, but rejected as absurd by those who attach even generic importance to the succulence of the indehiscent pericarp. This point cannot be decided with any degree of plausibility until we shall have a better knowledge of the different forms which the fruits of wild *Amygdali* may assume under various circumstances; but we may mention, as circumstances in some degree favouring the supposition that some kind of Almond is the parent of the Peach, the ancient tradition referred to by Targioni (with the remark that it is contradicted by Pliny, and by common sense) that the Peach in Persia was poisonous, and became innocuous when transported to Egypt, and the case quoted of a supposed hybrid raised in 1831 in Sig. Giuseppe Bartolucci's garden, at Colle di Val d'Else, from a Peach-stone which produced fruits at first exactly like Almonds, but which, as they ripened, assumed the appearance and succulence of Peaches, whilst the kernel remained sweet and oily, like those of Almonds. We might, also, refer to some bad varieties of Peach with very little juice to their pericarps, although we do not know of any which assume the flattened form of our Almond, a distinctive character which appears to us to be of considerable importance. The foliage and flowers of the two trees show little or no specific difference.

The Walnut (*Juglans regia*) is a native of the mountains of Asia, from the Caucasus almost to China. It is supposed to be the Enoz of the Bible. The Greeks had it from Asia; and Nicander, Theophrastus, and others mention it under the names of *Carya*, *Carya persica*, and *Carya basilike* (or Royal nut). Pliny informs us that it was introduced into Italy from Persia, an introduction which must have been of early date, for, although it be doubtful whether it is alluded to by Cato, it certainly is mentioned by Varro, who was born in the year 116 B.C. The Romans called it *Nux persica*, *Nux regia*, *Nux eubœa*, *Jovis glans*, *Dinglans*, *Juglans*, &c. They recognised several varieties, and amongst them the soft-shelled Walnut still cultivated, which several of the commentators have confounded with the Peach. In modern days, the cultivation has much extended, and the number of varieties considerably increased. Jean Bauhin noticed six only. Micheli, under Cosmo III. of Medici, describes thirty-seven, of which the original specimens are still preserved; some of these, however, are scarcely sufficiently distinct from each other.

The Nut (*Corylus Avellana*) is said by Pliny to derive the name of *Avellana* from Abellina in Asia, supposed to be the valley of Damascus, its native country. He adds, that it had been brought into Asia and Greece from Pontus, whence it was also called *Nux pontica*. Theophrastus calls these nuts by the name of *Heracliotic nuts*, a name derived from Heraclea, now Ponderachi, on the Asiatic shores of the Black Sea. Hippocrates gives them the name of *Carya thusia*. Dioscorides says they were also known by the name of *Leptocarya*, or small nuts. Other ancient writers confound the Nut with the Chestnut and the Walnut. But all the above indications of importation from the East relate only to particular varieties, for the species, as is well known, is common enough in Europe and a great part of Asia in a really wild indigenous state.

The Chestnut (*Castanea vesca*), celebrated amongst European trees for the enormous size it will attain, is already mentioned in the Bible. Theophrastus and Athenæus give it the name of *Eubœan Nut*, from the island of Eubœa, now Negropont, where it was peculiarly abundant. Pliny says that Chestnuts first came from Sardis, the ancient capital of Lydia, and not far from the modern Smyrna. Galen, who was a Lydian, confirms that origin, and says that they were also called *Balani leuceni*, from Leucene, situated on Mount Ida. Other writers, ancient and modern, give various Eastern countries as the native stations of the Chestnut, and even Giovanni Targioni-Tozzetti, our author's grandfather, believed them to be introduced only into Italy; but not only have the extensive Chestnut woods in the Apuan Alps and other parts of the Apennines, mentioned by Bertoloni, every appearance of being really indigenous, but further evidence that woods of this tree existed in Tuscany from very remote times, may be found in the number of places which have derived their names from them, such as *Castagna*, *Castagnaia*, *Castagneta*, &c. We may, indeed, safely give as the native country of the wild Chestnut, the south of Europe from Spain to the Caucasus. It does not extend to East India. The larger-fruited varieties which we import for eating, and which are generally distinguished in France and Italy under the name of

Marrons or Marrone, were probably those which were first introduced from the East by the Romans. Pliny enumerates eight different varieties. Micheli has forty-nine, most of which, however, from his own specimens, are, as in the case of the other fruits mentioned in his manuscript, founded upon distinctions too slight to be really available for their separation.

The Fig (*Ficus Carica*) is a native of the south of Europe, including Greece and Italy, of Northern Africa and of Western Asia. The wild type, known in Italy by the name of *Caprifico*, has indeed been distinguished by Gasparrini not only as a species but as a separate genus, but we cannot but concur with Professor Targioni in the opinion, confirmed by positive assertion on the part of practical pomologists both ancient and modern, that our garden Figs are of the same species, and have repeatedly been raised from seeds of the wild *Caprifico*. We find mention of the cultivation of Figs, and of the high estimation in which these fruits were held, in the very earliest writings, in the Holy Scriptures, and in Homer's *Iliad*. Those of Athens were celebrated for their exquisite flavour. Xerxes was tempted by them to undertake the conquest of Attica, in the same way that Cato urged the Romans to that of Carthage, a Fig in his hand. The number of varieties, however, produced in ancient Italy were not numerous. Six only were known in the time of Cato. Others were afterwards introduced from Negropont and Scio, according to Pliny, who gives a catalogue of thirty sorts. Their names are mostly taken from the countries whence they had been brought, such as the African, the Rhodiote, the Alexandrine, the Saguntine, &c., or from some great personage who had introduced or patronised them, such as the Pompeian from the great Pompey, the Livian from Livia, the wife of Augustus, &c. Macrobius, two centuries after Pliny, enumerates twenty-five, but generally under names different from those of Pliny.

Oranges, Lemons, Citrons, &c.—These are all of Eastern origin, and mostly introduced into Europe in comparatively modern days, but of very ancient and general cultivation in Asia. The varieties known are very numerous and difficult to reduce accurately to their species, on the limits of which botanists are much divided in opinion. Those who have bestowed the most pains in the investigation of Indian botany, and in whose judgment we should place the most confidence, have come to the conclusion that the Citron, the Orange, the Lemon, the Lime, and their numerous varieties now in circulation, are all derived from one botanical species, *Citrus medica*, indigenous to, and still found wild in, the mountains of East India. Others, it is true, tell us that the Citron, the Orange, and the Lime are to be found as distinct types in different valleys, even in the wild state; but these observations do not appear to have been made with that accuracy and critical caution which would be necessary in the case of trees so long and so generally cultivated. With regard to the Shaddock (*Citrus decumana*), it is almost universally admitted as a distinct species, although, at present, only known in the state of cultivation. It must be admitted also that it appears to present more constant characters than most of the others in the pubescence of its young shoots, and in the size of its flowers, besides the differences in the fruit; but Dr. Buchanan Hamilton, who is of great authority on such matters, and some others, are inclined to believe that this also may have originated in the *Citrus medica*. This point requires much farther investigation, and a better knowledge of the floras of South-eastern Asia, before we can come to any plausible conclusion. Professor Targioni gives copious details of the introduction into Tuscany and other parts of Italy, of many of the varieties there cultivated. It may suffice, for our present purpose, to extract a few notes on some of the more important races or species according as they may be considered. Among them all the earliest known was the Citron. It is not, however, that fruit nor any other Citrus, according to Professor Targioni, that we read of in the Bible under the name of Hadar as is asserted by some, nor yet is it anywhere alluded to by Homer. The first mention we have of it is in a comedy of Antiphanes quoted by Athenæus, in which it is said that the seeds of the Citron had then recently been sent by the King of Persia as a present to the Greeks. Theophrastus is the first who describes it; he tells us that the fruit was not eaten, but solely prized for its odour, and as a means of keeping the moths off woollen clothing. Among the Romans, we find an allusion to the Citron in Virgil's *Georgics*, but it does not appear to have been then yet introduced into Italy, for Columella, long after Virgil's death, made no mention of it, and Pliny, in his paraphrase as it were of the passage of Theophrastus, adds that it had been endeavoured to transport plants of the Citron which he calls *Malus medica* or *Malus assyria* into Italy; but without effect, as it would only grow in Media and Persia. Palladius, however, in the fifth century, gives many details of the modes of propagating and cultivating this tree, which he says he had carried on with success on his Sardinian and Neapolitan possessions. It was, therefore, in all probability, in the course of the third or fourth

century that the Citron was introduced and established in Italy. The mass of evidence collected by Professor Targioni seems to show that Oranges were first brought from India into Arabia in the ninth century, that they were unknown in Europe—or, at any rate, in Italy—in the eleventh; but were shortly afterwards carried westwards by the Moors. They were in cultivation at Seville towards the end of the twelfth century, and at Palermo in the thirteenth, and probably also in Italy; for it is said that St. Dominic planted an Orange for the convent of St. Sabina, in Rome, in the year 1200. In the course of the same thirteenth century, the crusaders found Citrons, Oranges, and Lemons very abundant in Palestine; and, in the following fourteenth, both Oranges and Lemons became common in several parts of Italy. It appears, however, that the original importation of Lemons from India into Arabia and Syria occurred about a century later than that of Oranges. The Shaddock is believed to have followed a different route in its migration into Europe. Most abundantly cultivated in, and possibly indigenous to, the south-eastern extremity of the Asiatic continent, it is said to have been carried from thence to the West Indies, and from Jamaica and Barbadoes to England, early in the eighteenth century. It was, however, certainly previously known in Italy, for it is described and figured by Ferrari, in 1646, as having been sent from Genoa to the garden of Carlo Cadenas, near Naples. There is no record of its first introduction to Genoa, whether from the east or the west. Innumerable varieties of Citrons are cultivated at Florence, where they have ever been great favourites as objects of curiosity, as much as for their flowers and fruits. Among them is a very singular one called *Bizzarria*, raised by hybridising and cross-grafting, in which the same tree produces Oranges, Lemons, and Citrons, often on the same branch, and sometimes combined into one fruit—a curious case, analogous to that of the well-known hybrid produced by grafting between the *Cytisus Laburnum* and *C. purpureus*.

The Grape Vine (*Vitis vinifera*) must, as already observed by Pliny, be ranked amongst trees on account of the prodigious size it will attain. Among the instances given of enormous Vines, we may quote the following: Pliny records a Vine in the Porticos of Livia, which overshadowed the whole area used as a promenade, and yielded annually twenty-two amphoras (154 gallons) of wine; the same writer states that he had seen at Populonia a statue of Jupiter, made of the trunk of a Vine, and that the columns of the temple of Juno at Metapontus, and the steps of that of Diana of Ephesus, were also of Vine wood. In more modern days, Soderini mentions a Vine in Portico di Romagna, which extended over 1,000 braccia (2,000 feet); in the *Mém. de l'Académie* of Paris 1737, a Muscat Vine at Balançon, is described, which, at twenty years old, produced 4,206 bunches of Grapes. Giovanni Targioni-Tozzetti, in his travels in Tuscany, quotes one in the woods near Montebamboli, the trunk of which two men could not embrace. Santi found a Vine at Castellottieri in the Maremma, torn up by a storm in 1787, whose trunk is preserved in the botanic gardens at Pisa, with a stem $5\frac{1}{2}$ feet in circumference; and Professor Targioni has himself recorded in the article "Botanical Chronology" in the "Dictionary of Natural History," printed at Florence by Batelli, two Vines near Figlini, in the Upper Vald'Arno, with trunks 5 feet in circumference. The doors of the Cathedral of Ravenna are made of Vine wood. This may be more especially observed in the Maremma, where it grows wild in the greatest abundance. It appears to be there, as in other parts of Southern Europe, truly indigenous, extending from thence over the greater part of South-central Asia; for the *Vitis indica*, on the testimony of the more recent Indian botanists, is by no means specifically distinct. From these wild Vines have evidently been raised the innumerable varieties cultivated over the greater part of Europe, Asia, and North Africa, and now carried out to all parts of the globe where the climate will admit of it. But the period when it was first taken into cultivation, is lost in the obscure ages of antiquity. We read in Genesis that after the flood Noah began to plant the Vine; the heathens ascribed its first introduction to their fabulous heroes or divinities, Diodorus Siculus to Osiris, Servius to Saturn, and in the most ancient times Italy was called *Cenotria* from the wine that it produced. We have already observed that the varieties of the Grape are most numerous; they are also often so strongly marked as to cause many writers to deny the possibility of their having all sprung from the wild Vine, but their apparent permanence is in most instances only due to their universal propagation, by cuttings or layers, not by seed. Pliny records eighty kinds, and many others are mentioned by Virgil, Columella, Varro, Macrobius, and other writers, which it is now impossible to recognise with certainty amongst the modern varieties, amounting in some collections to above three hundred.

[The preceding is a summary of a work entitled "Cenni storici sulla introduzione di varie piante nell'agricoltura ed orticoltura Toscana," by Dr. Antonio Targioni-Tozzetti; and is from the *Journal of the Royal Horticultural Society*.—ED.]

GARDEN STRUCTURES.

RICHARDSON'S PATENT GLASS-HOUSES.

OF the many novel designs of horticultural buildings seen at our flower-shows of late years, these houses are among the most interesting. They are, as will be seen by the accompanying illustration, light and elegant in appearance; and a distinguishing feature belonging to them is the perfect way in which the ventilation is managed. This is effected by narrow openings in the roof (9 inches wide) the full length of the lights from top to bottom, and from 4 to 5 feet apart, covered with glazed frames made perfectly weather-tight, with grooves up the sides, fitting down into galvanised iron tongues. These frames are 4 inches wider than the openings they cover, and, when lifted, are clear above the fixed lights, leaving an open

over the hot-water pipes, by which it is slightly tempered on entering the house.

These houses, which are manufactured by Messrs. Richardson, of Darlington, are easily erected according to directions sent with them, and though generally used as permanent structures, they are always made portable, so that they can at any time be removed at the expiration of a tenancy, and refixed without a pane of glass being disturbed. The roofs are constructed without rafters, which in other houses obscure so much light, and are cumbrous in appearance. Buildings of this kind can be heated in the same manner as any others, and are adapted for the growth of either plants or fruit. They are all glazed, painted, and fitted up complete before leaving the manufactory, every bolt-hole being made and each part numbered, so that there cannot be the least difficulty in refixing them by any ordinary carpenter. The special advantages claimed for them

Richardson's Patent Glass-house, showing their mode of ventilating.

space at both sides as large or as small as may be desired, thus allowing a free and even circulation of air throughout the house, and, at the same time, protecting the interior effectually from rain, wind, or a direct down-draught upon the plants. These ventilating roof-lights are made in either one or two parts, each separate set or range, from one end of the house to the other, being simultaneously opened and regulated by a single handle, placed in the most convenient position, and balanced in such a way as to be easily worked. Any ventilating light can, if desired, be thrown out of gear, so as not to open with the rest; or it may be lifted entirely off for glazing without the removal of screws. In the houses with front lights, bottom ventilation is obtained by wood-panelled doors, or flaps, along the full length, these also being opened and regulated by a single handle to each range, thus affording complete protection from the weather; the air is thus admitted below the level of any foliage, and immediately

by the patentees are the following:—1. The amount of roof ventilation is exactly in proportion to the area of the house, instead of being by the ordinary-sized opening along the top made regardless of the width of the roof.—2. The ventilation is not affected by rain or wind, the position of the ventilating lights completely protecting the interior of the house, and, when closed, forming a perfectly water-tight joint.—3. The opening and regulating of the ventilators is performed more quickly and easily than by any other system, being done instantaneously.—4. The method of bottom-ventilation underneath the plant staging, and immediately over the hot-water pipes, prevents cold draughts upon the plants.—5. The houses are portable, and legally removable by a tenant; can be easily taken down and refixed without disturbing the glass.—6. The training wires being fixed up the centre of the lights, have no obstruction from the sun's rays by the usual heavy rafters, and a free circulation of air is obtained between the plants and

glass over the whole roof.—7. If blinds are used, they are lifted simultaneously with the ventilators, thus allowing a circulation of air underneath, instead of obstructing the ventilation just when most needed. This principle of ventilation can also be applied to buildings of iron if preferred.

There is one important contrivance in these houses, when the roof ventilators are made in two lengths, as in the figure of a lean-to house on p. 293. This arrangement connects or disconnects the top parts from the bottom parts over the whole roof simultaneously, by means of a small lever handle; and another lever handle, close to it, opens and closes the whole length of the house simultaneously—either the upper parts, or both upper and lower parts, as may be required. The power employed in effecting this is merely nominal, the ventilating lights being nearly balanced. The section on p. 293 shows the positions of the ventilator when open and shut. It will be seen that, in the latter case it is most effectually closed, and entirely excludes both air and rain.

THE ROYAL GARDENS AT LISBON.

[FOR the following interesting communication we are indebted to Dr. E. Goeze, Curator of the Botanic Gardens at Coimbra, who is at present engaged in superintending the foundation of a botanic garden for the Polytechnic School at Lisbon, and who sends us this account of the Royal Gardens in compliance with the express desire of His Majesty King Don Fernando.]

It is a good while since the writer of the following lines came to reside in Portugal, where he has had many opportunities of admiring all the richness and abundance which vegetation displays in the sunny south. Coming from a more northern clime, this country appeared to him, at his first arrival, like a vast garden, for, wherever he met with plants, they were represented by forms either quite new, or at least often only known to him by scanty specimens cultivated under glass. Well does he remember the day when he landed at the Lisbon Custom House, and when mighty Date Palms, tall Musas, slender Sugar-canes, flowering Agaves, luxuriantly-growing Bougainvilleas with thousands of brightly-coloured bracts, gave him his first and best welcome. Since then, some seven or eight years have passed by, and he, sharing the general disposition of mankind—that of not feeling satisfied with the present, but always wishing for something better—has long since ceased to entertain an unqualified admiration for the plants just named, and has been looking out for forms still finer, still more perfect; and, to a great extent, he has been successful in his researches. He had been living, till last year, chiefly in the north of Portugal, where nature, though beautiful, does not exhibit all her splendour; but, since then, he has been enabled to remove to Lisbon.

What beauties doth Lisbon first unfold!
Her image floating in that noble tide
Which poets vainly pave with sands of gold.

These “sands of gold” he discovered in all the treasures which mother Nature has bestowed upon the vegetable kingdom, and, of which, some private gardens in the capital and its neighbourhood may especially boast. He, therefore, at once asks the reader to accompany him on a walk through the Gardens of Necessidades, the royal winter residence of the King of Portugal, reserving for another occasion an excursion through the Gardens of the Penna, at Cintra, a summer residence, where His Majesty King Don Fernando and his Queen have of late introduced such remarkable features of exotic vegetation as to render both Penna and Necessidades the first establishments of acclimatisation in Portugal.

Situated in very close proximity to the river, or, as one might almost say, to the sea, the plants of Necessidades Gardens would have encountered, in the briny sea winds, which often occur here, the greatest obstacle to a vigorous growth if His Majesty had not, first of all provided, towards the water-side, high shelters, consisting of thick shrubberies of more hardy species. But, not satisfied with this, Don Fernando created in the large garden a small reserved one, especially destined to receive the finest specimens of his collections. This beautiful little place is not only sheltered by shrubberies, but also by high walls and one side of the Palace, so that cold and

destructive winds cannot come near it. But there was another difficulty to overcome. The soil about Lisbon, in general, is very heavy and compact, and to render it fit for more tender kinds of plants, thousands of cart-loads of rich vegetable mould had to be mixed up with the native soil. Water here is in abundance, and of very good quality; so, with exterior conditions such as have been described, and the interest which His Majesty takes in horticulture, one cannot feel surprised at the result being most satisfactory. The Palms, the kings of the vegetable world, and the allied family, the Cycads, claim our attention in the first instance. The famous Coquita Palm, of Chili, *Jubæa spectabilis*, is represented here by an enormous and most splendid specimen, in fact, very probably the finest plant of it grown in Europe. Some twenty years ago His Majesty bought a small plant of it from M. Van Houtte, and had it immediately planted out in the open air. Palms, as we well know, are very slow in starting, but when once they begin to grow, they do so rapidly, provided they find all the conditions necessary to growth, such as rich soil, abundance of water during the dry season, and a well sheltered situation. So the young *Jubæa* at Necessidades has become already quite a large specimen, measuring, at its base, 13 feet 8 inches in circumference, with a height of, perhaps, over 32 feet. It is of a more compact growth, than one expects to find in a lofty Palm, but, all things considered, it is a striking specimen, and well worth attention. The *Livistona chinensis*, Mart. (*Latania borbonica*, Lam.), of more recent introduction in this garden, at least, so far as the open air is concerned, is making every effort to overtake the older *Jubæa*; and there are several plants of it, which show such a vigour and luxuriance that there is no knowing what size they may attain. This beautiful Chinese species is certainly one of the best acquisitions for the gardens of Southern Europe, and it is very much to be regretted that it is still a rare plant in Portugal. Next to it, a very tall and healthy specimen of *Sabal Adansonii* claims attention, and it is difficult to say whether to this, or to one of the previously-mentioned Palms, the crown of beauty should be awarded. This species of *Sabal* has already fruited in this garden; the seeds have proved to be good, and there are now a great many fine healthy plants of it in large pots. The Cabbage-Tree of New South Wales, *Livistona australis* (*Corypha australis*), and *Seaforthia elegans* (also from Australia), are not less attractive, and there are certainly but very few specimens in some of the larger Palm-houses of Europe, which can be compared in size and beauty with those grown at Necessidades.

In continuing our walk, a vast group of *Chamærops* attracts the eye; and these plants, in their artistical arrangements, their different shades of colour, and their luxuriant growth, are really the *ne plus ultra* of perfection which one may expect in such a plantation. This group is composed of four species, and consists of about thirty plants, viz., *Chamærops humilis*, *C. excelsa*, *C. Fortunei*, and *C. Palmetto*, several of them laden with fruit, others just beginning to flower. To heighten the contrast, some tall plants of the red and yellow-striped *Yucca* have been mixed with them. The *Phoenix dactylifera* is the most common Palm in Portuguese gardens, and very often the traveller meets with some very tall specimens of it. There are at least a hundred strong plants in this garden, some of which, with very tall stems, were originally planted out as single plants, but they more frequently occur in groups of from between twenty to thirty specimens planted together. This species fruits here almost every year, but it seldom happens, except we get a very dry and hot summer, that the Dates ripen, and, even then, they are inferior to those imported from Africa. *Phoenix reclinata*, from the Cape of Good Hope, is well represented here by fine plants, and its characteristic port. The recurved leaves recall to our memory the late Dr. Seemann's words—

Ye bending Palms, that seem to look
Pleased o'er your image in the brook.

Japanese plants, in general, do not seem to like the Lisbon climate; and that is the case, too, with *Rhapis flabelliformis*, which, planted out here in different places, does not seem to appreciate the privilege of growing in a royal garden. Though the Cycads are much less numerous here than the Palms (numbering, perhaps, only half-a-dozen species), they

excite just as much interest, and claim our admiration in no less a degree. First of all there is a most beautiful *Dion edule*, to be noticed, showing far better health than any plants we have ever seen cultivated under glass. Only a few years ago, His Majesty had this *Dion* planted out in the open air, and the rapidity with which it has grown since then is somewhat prodigious. Quite in its neighbourhood we meet with an enormous trunk of *Cycas revoluta* with seven heads or crowns, of which two show the peculiar inflorescence, with a great many ripe seeds. There are at least a dozen veterans of this species at *Necessidades*, all imported trunks, not to speak of the many young plants obtained here from seed. Pushing on, we make the acquaintance of more striking subjects; first a splendid specimen plant of *Cycas circinalis*, from Malabar, then a stout *Encephalartos horridus* with a good many dark-coloured fronds, and at last a nice-looking species of *Zamia*. So we have here, growing in the open air, Cycads from Japan, Mexico, the East Indies, and the Cape of Good Hope. They are soon to be associated, let us venture to hope, with a few Australian species. What an interesting picture of the geographical distribution of this family, which seem to be well fitted for acclimatisation in southern Europe! A few other Monocotyledons cannot be passed over in silence. The *Bambusas* are growing here just as luxuriantly and rapidly as

in their native countries; one species in particular is of enormous height, and forms large tufts. But, perhaps, some of our readers would prefer to stop a little longer at a thick undergrowth of *Bambusa nigra*, in order to select one of the straight black and shining shoots for a walking-stick. These *Bambusas* are growing on the borders of small artificial lakes, and are here and

there mixed up with *Cyperus*, *Papyrus*, and several kinds of *Hedychiums*. These latter are not in flower at this time of the year, but they are covered with fruit, and the fleshy, red, shining seed-vessels offer a nice contrast to the different shades of green. *Strelitzia augusta* is of great strength, and attains

the height of a tall *Musa*; the other species, *Strelitzia Reginae* flourishes equally well here, and both flower abundantly every year. *Dracæna Draco* is a somewhat common plant in Lisbon, but in attaining such dimensions as in this garden, it always presents a most interesting and picturesque sight. *Cordyline australis*, *Dracæna heliconiæfolia*, and some more of the *Dracæna* tribe, seem to be equally at home here, and one might suppose the same of a very old *Testudinaria elephantipes*. The tree, *par excellence*, in this garden is, perhaps, the *Araucaria excelsa*, to be found here by hundreds, one might almost say, a great many of them showing stems of considerable height. But when this tree has attained a certain age, or, as it is, perhaps, more correct to say, has come to a certain height, it very often decreases in beauty and increases in stiffness. Very interesting it is to compare these species,

which form large groups here, with the much less common *Araucaria columnaris*, of which we met with three really perfect specimens. There cannot be the slightest doubt that the latter, in showing a very compact and still very regular growth, is the finer of the two species. More than one good opportunity for comparison between allied species was presented to us in this garden, and, certainly, if we examine the plantations in this way, they increase in variety and become still more instructive. Of *Araucaria brasiliensis*, there are here, as in other gardens of Portugal, very tall and fine trees; this is, indeed, the most common species in the kingdom, and a good many cones, with perfect seed, are gathered from it every year. *Araucaria Cookii* and *A. Cunninghamii* are not forgotten, and are contending with the other species in rapid growth. Several kinds of *Podocarpus* and some plants of *Thuja pendula* may also claim special mention amongst the *Coniferae*. As Oranges, Citrons, and others of the Citron tribe, are so very common in this country, it is, perhaps, just as well not to mention them here, but another genus belonging to *Aurantiaceæ*, viz., *Sclerostylis*, of Blume, if we are not very much mistaken, is to be found in this garden, and certainly we shall watch it closely to see if it produces flowers and fruit. Another interesting tropical fruit-tree is the *Mangifera indica*, which promises to do well out-of-doors. The species of *Aralias* and

Ficus are so numerous in *Necessidades*, that a mere enumeration would be a difficult task; indeed, their number is legion. Both *Aralias* and *Ficus* thrive exceedingly well, and here, where they seem to have acquired their full size, one is well enabled to form an exact idea of the beauty and variety of their foliage. Other thick shrubberies are made up of different kinds of *Pitto-*

House with ventilators in divisions (see p. 292).

sporum and *Myoporum*, and, to avoid monotony, rich flowering plants of *Salvia involucrata*, a few varieties of *Lantanas*, *Plumbago capensis*, *Sparmannia africana*, *Adhatoda vasica*, and a great many *Roses* relieve the dark-coloured green foliage of the above-mentioned shrubs. Beautiful creepers

cover the walls and, sometimes, the trunks of some dead trees, left here on purpose. Long-flowered *Solantras*, with their almost leathery leaves, *Rosa Banksiæ*, with very thick stems and white and yellow flowers, richly-coloured *Passion-flowers*, *Tacsonias*, and *Bougainvillæas*, in three or

four varieties, are the most prominent among them. *Begonias*, as they are employed here, to border small walks, produce a very good effect, and *Fuchsias*, as well as *Geraniums* and *Pelargoniums*, cultivated for similar purposes, are very conspicuous. Though glass-houses are not exactly required under the Lisbon climate, they are, nevertheless, wanted where plant-growing is extended over so many families from tropical countries as are found in *Necessidades Gardens*. A very long and, apparently, quite new glass-house is destined for the cultivation of Pine-apples, of which there are a great many

Section of ventilator.

young and healthy plants, which promise to fruit next year. Some fine plants of *Cocos nucifera*, which germinated here, seem to live in suitable companionship with the Pines. But the most striking vegetation in this house is represented by a very strong plant of *Vanilla aromatica*, covering one of its long walls. This *Vanilla* produces abundance of flowers every year, and we are in hopes, that it may, with a little artificial assistance, produce ripe fruits next year, an occurrence the more interesting, because it has not yet taken place in this country. The large conservatory, with cupola and gallery, contains some very choice plants, especially of Palms and Ferns. Among the former we noticed a very tall plant of *Caryota urens*, then fine specimens of *Thrinax parviflora*, *Chamaedoreas*, and several *Areceas* and *Cocos*. A very valuable collection of plants arrived a short while ago from the Brazils, a present from His Majesty the Emperor of the Brazils to his royal cousin, King Don Fernando. Most of these plants had not suffered at all from the sea voyage, and some five or six big trunks of *Lomaria imperialis*, which have already pushed many young fronds, seemed to us the most valuable amongst them.

A mere collection of rare and beautiful plants would not suffice to make this garden so attractive to the visitor if His Majesty had neglected or ignored the principal requirements of landscape-gardening, but here everything is in its right place, and so we find a good exemplification of the union of science with a refined taste for scenery. From different points one may enjoy the loveliest views on the river and its opposite banks, and there are some vistas cut through groups of trees and shrubs, which really resemble fine paintings. The walks are laid down with elegance, kept in capital order, and very often bordered with thousands of *Aloe latifolia*, just now in full flower, and exhibiting, with their brilliant red spikes, a beautiful aspect. Some very nice artificial lakes, with undulating banks, and good pieces of rockery, produce still more variety, and, to give to the whole scene still more life, crowds of beautifully-coloured water-fowl add interest to the lake itself. We have almost finished our walk, let us cast one more glance over this beautiful garden before leaving it. On our left there are the royal groups of Palms, straight before us our eyes meet with splendid *Araucarias* and not less splendid *Magnolias*, the branches of which are reaching to the ground, while on our right we have the magnificent Palace of *Necessidades*, the royal dwelling, so intimately connected with glorious and also sad events in the history of Portugal.

Lisbon.

EDMUND GOMME.

AN ORDINARY COTTAGE MADE BEAUTIFUL.

THOSE who have not tried the experiment can scarcely imagine how the most prosaic forms of bricks and mortar may be made picturesque and tasteful at very small cost. The repulsive dreariness of the usual bare front of a modern labourer's cottage, with nothing to vary the aspect of its naked walls but the ugly square openings of the windows and doors, may, with very little cost, a scintillation of taste, and a small modicum of outlay (scarcely more than a few shillings) be, in a single season, transformed into a picturesque rustic façade, positively attractive, instead of all but actually ugly. A porch should be the first addition, and a little bit of carpentering forming the roof, as shown in the annexed light, but spirited, little sketch, is the only matter requiring a trifling outlay. It should be supported on unbarked uprights, of any readily available wood; four sticks of young Larch, from the thinning of an overcrowded plantation, being as good for the purpose as anything that can be suggested. A few ladder-like cross-barrings should be added, and the foundation for an exquisitely pretty porch has been successfully laid. Climbing plants are the next requisites. A pink China Rose, as flowering nearly all the year round, and its foliage being nearly evergreen, may be the first planted, for it possesses a never-failing charm. It is so elegantly and daintily delicate both in flower and leaf, and yet defies our most cruel frosts. It is one of those "things of beauty" which, as Keats has so poetically said, are "a joy for ever." There may be at its base the crimson dwarf of its own kith and kin, for the sake of contrast of colour. Two kinds of *Clematis* may next occupy posts of honour. On one side should be *C. montana*, with its shower

of snow-flake blossoms, and on the other the brilliant-flowered *C. Jackmanni*, the huge and abundant drooping blossoms of which will serve in their season to surround our cottage-porch with a glory of purple flower-drapery, which no palace entrance could surpass in splendour. Then there may be dropped into the soil, in early April (but not too profusely) a few seeds of *Convolvulus major*, common climbing *Tropæolum*, and *T. canariense*. This combination will, in June, July, and August form a gorgeous mass of varied colour, which neither the plants of glowing tropical valleys nor the rarest of the exotic flowers luxuriating in the artificial heat of our palatial stoves can surpass.

The crowning of our porch-roof with gracefully fantastic wreathings will arrange itself without aid, and with a wild grace and beauty that might have driven the designer of the Corinthian capital to despair; but care will be required to make the lower portion of our structure equal to its crowning cornice. The Grecian carver threw all his energy of device into the capital; but our chief aim, if only for the charm of change, must be the base. Neither the *Clematis* nor the *Rose* give out either flowers or beautiful foliage near the lower portions of their stems. We have, therefore, to provide another and distinct source of ornamentation, and it shall be one even more beautiful than that formed by the *Acanthus*, which furnished the beauty-loving Greek with his charming device for the capitals of his elegantly-fluted columns. It shall be, on either side, a group of Ferns, the most graceful

An ornamental cottage porch.

of all the green carpetings with which Nature has clothed the earth. The few expressive touches of our sketch may serve to convey some idea of the graceful living base from which our rustic columns are made to spring. What a model for an architect of genius, who could combine such a hint with other æsthetic requirements!

At the back of the porch, close to the cottage wall, and so as not to encroach upon the domain of the *Rose* and *Clematis*, a slow-growing *Ivy* may be added for the sake of its shining evergreen leaves; and it should be one of the variegated kinds, perhaps, as they are none of them so profuse in growth, or so ambitious of taking the lead and smothering up their rival climbers as are their more rampant green congeners. About the windows the common green *Ivy* may be planted, if kept within bounds by occasional shearing. But such cropping should not extend to the top, in order that too much formality may be avoided, and also to afford an opportunity for the introduction of a *China Rose* or two, whose flowers, peeping out among the dark *Ivy*, which should be left clustering about the eaves, will produce the most charming effect. I have often noticed examples of such a display of the delicate sea-shell pink of *China Rose* blossoms among the deep glossy green of the *Ivy*, and the combination never failed to be pleasing and highly picturesque. There might also be a plant or two of the *November* and *December*-flowering yellow *Jasmine*, whose starlike flowers—brilliant as "patines of bright gold"—would sparkle among the sombre green of the *Ivy* at a time when the *Rose*-flowers are few

and far between; and this effect, followed by the early scarlet flowers of a *Cydonia japonica*, which are produced in such profusion late in February and early in March, would carry on a display of floral colour till the season for the earliest China Rose-blossoms to come round again.

There should always be a narrow flower-border; even if there is no room for a small patch of flower garden in front, for there is always room for a narrow strip close to the wall, which should be so planted as always to present something fair to look upon. This is a very easy matter in the summer months, when numberless kinds of hardy annuals and perennials are available; but for late autumn, and the depth of winter, a little care and thought must be bestowed. The *Anemone japonica*, autumnal *Crocus*, and late *Michaelmas Daisies*, will carry on to December, when a large tuft of *Christmas Rose* on each side of the entrance will afford a gleam of brightness over a dreary period. There should also be groups of winter *Aconites* to follow, whose yellow flowers will warm up the pallor of the graceful *Snowdrops*, which must on no account be forgotten. These should be followed by red, blue, and white *Hepaticas* and clumps of one of Shakespeare's favourite flowers, the yellow *Daffodil*, "that take the winds of March with beauty;" mauve and orange *Crocuses* will then begin to bloom, mingling their purple and gold with the rich tawney-browns of the *Polyanthus*, and the fresh pale yellow of the wild wood *Primrose*. After that, whole tribes of the good old-fashioned flowers of cottage-gardens begin to bloom in profusion; and the gay colouring of the little strip of flower-border will then take care of itself. In this way the depressing bareness of the most formal and naked-looking cottage may be made absolutely attractive, however humble its scale, or however unpromising its character; the dressing up of the bare door-way with a picturesque porch, similar to the one shown in the annexed sketch, being, of course, the most essential of the improvements suggested.

H. N. H.

ROFFEA FOR TYING PURPOSES.

HAVE used this, Grass I suppose I may call it, for tying both indoors and in the open air for some time; and, for tying Peaches, Vines, plants, &c., I like it much; but, if used under circumstances where it is constantly damp, it rots and drops to pieces, almost like tinder, in about three weeks. I may mention a case in point. About a month ago, I grafted a number of *Maréchal Niel* Roses on *Manetti* stocks in the way I have just described. When the grafts began to grow and they were lifted for potting, the *Roffea* with which the grafts had been bound was completely decayed and dropped to pieces. Of course, I do not object to its use for this purpose on that account, as the plants were immediately potted in warm soil, and, the junction being covered, they felt no check; but, I mention it now, because I was surprised to see how thoroughly it had decayed in so short a time, whilst, in a dry place, it retains its strength for a long period. Twelve months ago, I tied up a lot of heavy creepers with it on a lofty wall from 30 to 40 feet high, and, therefore, the ties had to sustain a considerable weight; not one gave way, and they are now to all appearance sound. I have used it also in the *Vineries*, where, including the combined weight of fruit and wood, a strong material is necessary, and when the Vines were taken down for cleaning, &c., the ties seemed perfectly sound. E. HOBDAV.

Practical Uses of the Poet's *Asphodel* (*A. ramosus*).—Everyone is familiar with the pretty white-flowered *Asphodel* of our gardens. In the south of Europe, and apparently on both sides of the basin of the Mediterranean, it is extremely abundant; in times of scarcity its acrid fasciculated roots, after much boiling, have been eaten by the poor. In the Paris Exhibition of 1855, there were shown bottles of alcohol extracted from the *Asphodel*; specimens of the residuum of the roots after being twice distilled; paper-stuff from the stalks and leaves—card-paper and writing-papers of various qualities, manufactured from the same, and mixed in various proportions with rags and common paper-stuff. The stalks and leaves contain a remarkably tenacious fibre, fine, strong, and flexible. The distillation of *Asphodel* root has been already pursued, and with considerable success, in Algeria; but the immense abundance of the plant in Tuscany, where it has hitherto been considered only a pernicious and most ineradicable weed, points to the advantage of endeavouring to turn it to account.—P. L. SIMMONDS.

THE KITCHEN GARDEN.

PREPARING AND SOWING ASPARAGUS BEDS.

Now is the time to attend to this work; fresh plantations may be formed, seeds sown, and winter coverings removed. Many sow the seeds where the plants are intended to remain, and, when up, thin them to the required distances apart; but I think it better to sow them in lines, from 8 to 12 inches apart, in a well-manured bed, made on a warm south border, watering them in dry weather, keeping down weeds, and stirring the ground amongst them occasionally with a hoe. Towards the end of autumn, when the tops have ripened, they should be removed, and a few inches of dung spread on the surface to protect the young crowns from frost. About the middle of the following March, the covering may be taken off, and by the 1st of April the young plants will be in good order for transplanting. In preparing a plot for this purpose, choose an open situation, free from trees or roots, and damp ground seems better suited for *Asparagus* than that which is too dry. About the 1st of November, the ground to be planted should be heavily manured and trenched two spades in depth; the bottom of each trench should be forked up, and the dung carefully mixed with the soil in the operation of trenching. A piece of ground, thus prepared, may now be manured with, at least, 6 inches of rotten dung, and trenched over again two spades deep as before; but, this time, all the manure should be spread equally in the bottom of each trench. The width of the beds may be made a matter of convenience. Some grow their *Asparagus* in beds 2 feet wide, some in 4 feet, and others in 6-foot beds. Beds 7 feet wide, planted with three rows, with 2-foot alleys between the beds, answer every purpose. After the beds are marked out, a line should be stretched from end to end, 10 inches from the outer edge; the soil should then be cut down straight from the line with a spade, and thrown out towards the centre. The plants should then be carefully lifted with a fork, exposing the roots as little as possible, either to sun or air, and re-planted about a foot apart, spreading the roots regularly in the trench, and allowing the crowns to be about an inch below the surface. The first line being thus planted, the second should then be made in the centre of the bed, 14 inches from the first, each plant alternating with those in the first row, while in the third row they should stand opposite the first, thus alternating with those in the centre row. After the planting has been finished, the beds should be carefully raked over and straightened up, when no further attention will be needed, except hoeing and weeding during the summer. As a winter-dressing, about 6 inches of rotten dung should be spread on the surface, and the loose soil from the alleys should be spread over it. The latter can be raked back again previous to the plants starting into growth. The roughest of the covering should be removed about the beginning of March, but as much as possible of it should be carefully forked into the beds. No cutting should be done until at least the second year after planting; as a rule, three years, indeed, should elapse before cutting commences, and, if very large heads are wanted, four years.

JAMES MORRISON.

Wotton Gardens, Aylesbury.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Clubbing in Cabbages.—What can I do to prevent clubbing? Our garden, which has been in cultivation about twenty years, is frequently trenched and kept in a good state of cultivation. I have had gas-lime dug in in winter; I have dipped the roots of my Cabbages in a mixture of soot, lime, and clay before transplanting them; I have covered the roots with a mixture of burnt ashes and fresh soil; but nothing which I have done prevents clubbing.—E. GALLIE, *Edgebaston*. [See Mr. Baines's remarks on this subject in another column (p. 282).—Ed.]

Depth to Plant Peas.—Mr. F. R. Elliott gives an account, in the *Gardeners' Monthly*, of some experiments performed fifteen years ago to determine the best depth to plant Peas. Buried 1 and 2 inches deep, they came up soon, bore early; but did not last long. At 3 and 4 inches in depth, they came up three or four days later, did not bear quite so early; but gave a heavier crop, and continued for a longer time. At 5 and 6 inches depth, they appeared two or three days later, grew about as vigorously as the others, and continued still later. At 8 and 10 inches, they were long in coming up, and did not produce so well. A few straggling feeble plants came up from 12 inch planting. Mr. Elliott thinks about 4 inches the most profitable depth in strong soils, and a little more in light soils.

THE ARBORETUM.

VIRGINIAN CREEPERS.

Of the species in cultivation the following are worthy of special mention:—

Ampelopsis hederacea (Virginia Creeper).—This, which is found wild over a large portion of Canada and the United States, is a vigorous deciduous climber—reaching, sometimes, heights of from 40 to 50 feet—with large digitate leaves of a warm green colour in early summer, but changing on the approach of autumn to a bright red, giving the plant at that season a peculiarly grand appearance, amply compensating for its small inconspicuous flowers, which, being of a greenish-white, are not of themselves attractive. This shrub is one of the most ornamental of hardy climbers, unrivalled for covering walls and houses, to which it clings closely and firmly with no other aid than that of its tendrils; and that few plants withstand the smoke and dust of towns so well, is proved by the frequency with which it is to be seen growing, and even thriving, on windows and balconies in the most crowded thoroughfares, with no other soil than that afforded by a shallow box, or moderate-sized flower-pot. In order to keep it tidy, it should be trimmed or pruned annually, the best time for the operation being in spring, before it begins to grow.

A. bipinnata (Two-winged Virginia Creeper).—This is another American deciduous species, found growing in similar situations to the preceding. It has a much dwarfer habit of growth, rarely rising to greater heights than from 10 to 20 feet. The leaves are bipinnate, elegantly lobed, and assume that beautiful crimson tint in autumn so characteristic of the genus. For low walls and trellis screens, it is a most useful and handsome climber, and, like all the other species, not particular as to soil.

A. Veitchii (Mr. Veitch's Ampelopsis).—This, the *A. tricuspidata* of some writers, is a Japan deciduous species, first sent home to this country in 1864. Its habit of growth is much more slender than the American species, the leaves very small, varying in form from trifoliate to three-lobed, of a bright reddish-green in summer, and changing in autumn to a rich shiny brown. It is a singularly elegant and distinct little plant, quite hardy and well-worthy of a prominent place on low garden-walls, screens, or, indeed, wherever a neat moderate-growing climber is to be desired. A dry light soil with a good proportion of well decomposed leaf-mould, or other vegetable matter, seems to suit it best, and the beautiful tints of its foliage are brought out to the greatest perfection when fully exposed to the sun.—*The Gardener*.

Holly from Seeds.—Will you kindly tell me when to sow seeds of Holly, and what soil to sow them in? if in a box or in an open border? I gathered the seeds in January, and have kept them in silver-sand.—SUBSCRIBER. [As the seeds of the common Holly do not come up the first year, the berries are best mixed with dry earth in a large flower pot, and buried in the ground for a year; but if the seeds are to be sown as soon as gathered, then the berries should be thrown into a tub of water and rubbed between the hands until the seeds are divested of the thick glutinous covering which surrounds them. The seeds should be sown either in the autumn or spring, in finely-prepared soil in beds in the open ground and covered about $\frac{1}{4}$ of an inch deep; and, if the beds are covered with the fronds of Fern, they will protect the soil from heat and drought and greatly facilitate the progress of germination. The young plants will come up in June, and should not be disturbed for two years.—ED.]

The Monterey Cypress (*Cupressus macrocarpa*).—I am glad you have directed attention to this Cypress, though I do not think the question is yet definitely settled as to the difference between it and *C. Lambertiana*. Some fifteen or twenty years ago, among the Conifers which were planted on Belvedere, near Mullingar, in Ireland, were some Cypresses sent as *macrocarpa*, and since called by this name. They are now very handsome trees, of considerable size, spreading like a Cedar, and rather dark in foliage. They have been, hitherto, quite hardy, transplant well, and are singularly fine and picturesque in character. At Keir, near Stirling, remarkable for the number of its Coniferous trees, are some Cypresses of the same age as mine. They are tall, columnar, handsome, and somewhat lighter in foliage than mine. They are known there as *Lambertiana*. I have had several Cypresses, described as *macrocarpa*, sent me from different nurseries. Some were spreading, some columnar, but none equal to my own in vigour, colour, or constitution; indeed, I lost a dozen of them in one winter. If there are two trees so dissimilar in appearance as those called *C. macrocarpa* and *Lambertiana*, springing from one species, and produced by seed, sometimes horizontal, sometimes upright, it is a very remarkable fact. But I cannot help suspecting that, whether my tree be *Lambertiana* or *macrocarpa*, it is not now a common tree; that the true variety of the Monterey

Cypress is scarce, and that some other weaker and less hardy sort has been substituted for it. I do not think that the fact of the *C. Lambertiana* growing sometimes upright, sometimes spreading, is quite a case in point, as the character of the tree remains unaltered, and there is not the same dissimilarity of appearance which I have observed in the two forms of the Monterey Cypress—at least, there is quite sufficient ground for further inquiry on this subject.—BRINSLEY MARLAY.

WORK FOR THE WEEK.

Flower Garden.

SPRING flowers are now daily becoming so plentiful that herbaceous and shrubby borders are getting quite attractive; on lawns, too, are tufts of Crocuses, Snowdrops, Dog's-tooth Violets, and other favourite bulbous plants that annually spring up and unfold their beauties when once planted in such positions. They get cut down prematurely by the first turn of the scythe or lawn-mower, but the following year they spring up again, numerically increased, and with greater vigour than before. Under the wide-spreading canopy of large deciduous trees a spring carpet of white, yellow, and blue furnished by early-blooming bulbs, is most desirable and pleasing, and in such a situation they thrive where not a vestige of Grass will grow. Only the commoner kinds, however, should be used in this manner, for the finer ones, if so treated, are apt to degenerate; hence the necessity of a good position for them, where they can retain their foliage until the bulbs are properly matured, when the foliage may be cut over, and the surface of the ground carpeted with annual or other shallow-rooting plants. Lawns should be swept, rolled, and, if necessary, mowed. Where they are covered with Moss it should be raked off, a top-dressing of finely-sifted soil applied, and some Grass and white Clover seeds sown at the same time. The top-dressing should be equally spread, raked smoothly and level, and then well rolled. Should the lawn be thinly covered with Grass, although free from Moss, a top-dressing of good soil with some guano mixed with it, and also a sprinkling of Grass and Clover seed will greatly renovate the turf; before applying it, however, go over the surface with an iron-toothed rake, so that the old and new soil may the more readily unite; soot, salt, or guano, applied alone in rainy weather, is also productive of excellent results. If the edge of lawns or Grass walks are well rolled before trimming them, the operation can be more neatly and accurately done. Turfing of lawn may still be performed, but the sooner such work is finished now the better will the Grass stand the summer's drought. In the absence of turf, seeds may be used, but in that case a long time elapses before a thick close carpet can be formed, and continuous attention in the way of mowing is requisite. Alterations in the flower-garden or pleasure-grounds may still be proceeded with. The planting of deciduous trees cannot, however, be too speedily finished now for the season; evergreens may be transplanted later. Coniferous trees, as a rule, transplant very well in the spring time. In planting, preserve the roots as entire as possible, and do not bury them more deeply than is necessary; stake such as require support. Instead of roughly filling in the soil, it should be well and carefully worked in amongst the roots with the hand, and a good soaking of water at planting time has also an excellent effect in settling the soil about the roots. Rose-planting should now be proceeded with; indeed, where the trees are grown on their own roots, this is a good season for transplanting them. Roses in general may now be pruned. A thinning of the shoots is sufficient for strong-growing kinds, whilst some of the dwarfer and more compact sorts bear a severe shortening of the shoots with impunity. A good dressing of manure should now be forked into Rose beds or borders. Transplant spring-flowering plants as occasion requires, and dust some fresh air-slaked lime amongst them to keep off slugs. Transplant seedling Pansies, and pinch the tops out of old plants to encourage the production of laterals and continuity of flowering. Transplant autumn-sown Mimuluses and annuals, such as Candytuft, Nemophila, and Eschscholtzia, where they are in bloom. Biennials, such as Rockets, Sweet Williams, Wallflowers, Hollyhocks, Canterbury Bells, Foxgloves, Anchusas, &c., may also be similarly treated. Annuals for early flowering may be sown in light soils and in warm situations; sow thinly, and thin out a little immediately after the seeds germinate. Remove last year's shoots, if any, from herbaceous plants, and give the borders in which they grow a good dressing of well-decayed manure. Overgrown specimens should be lifted, divided, and transplanted either permanently or in nursery lines, as may be most convenient. Where mulchings of leaves, straw, or litter were placed around the necks of plants of Pampas Grass, Tritomas, &c., remove them gradually. The protection given to Myrtles, Loquats, Clematises, and all but hardy plants on walls, may now be partially, and, in many cases, wholly removed. Finish

planting Box, Euonymus, Santolina, Japanese Honeysuckle, and Ivy edgings. If any of these are turned out of pots, shake the soil from their roots, and spread the latter well out; after such treatment they may remain stationary, or nearly so, for a few weeks, but when they begin to grow they will proceed with a vigour unknown to plants committed to the soil with matted roots. The golden-variegated Thyme is now popular as an edging plant, and deservedly so, for it is quite hardy; old plants of it may now be lifted, divided, and transplanted permanently; any in pots subjected to an increased temperature will afford cuttings freely, and they will root as readily as Verbenas. An edging, formed by dividing old plants last autumn, has now scarcely a plant in it alive, whereas one formed in the same way alongside of it last spring has withstood the winter unscathed. *Campanula carpatica*, *Stachys lanata*, *Cheiranthus Marshalli*, *Cerastium*, &c., make excellent edgings, and this is the right time for forming them.

Bedding Plants.

From greenhouse and other plant and fruit houses it may now be necessary to remove *Pelargoniums* into frames, in which they will keep perfectly well until bedding-out time. By keeping them in warm quarters, however, better supplies of cuttings are obtained. Proceed with the propagation of different subjects from seeds, cuttings, or division, as speedily as possible; for, the stronger the plants are before they are planted out the better will they flower. Prick off, from the seed-pans into other pans or boxes, *Lobelias*, *Wigandias*, *Petunias*, *Golden Feverfew*, *French and African Marigolds*, *Amarantuses*, *Brachycome*, &c. Sow some crimson-leaved Beet, for flower-garden purposes, in a very gentle heat or close pit. Pot off cuttings of all sorts as they become rooted; and after they have yielded up their tops for cuttings they may be placed in a position a little cooler than the propagating pit, unless a further supply is required. Re-pot autumn-propagated *Pelargoniums*, and place them in a close pit or frame for a time. Give them plenty of water, but do not allow them to be saturated so much as to generate damp. Prick into boxes of light soil, seedlings and leaf-cuttings or succulents, and keep them in a position near the glass. Put into frames 6 or 8 inches in depth of light soil; pack it firmly and into it transplant the autumn cuttings of *Verbenas*, *Ageratums*, *Lobelias*, *Calceolarias*, *Salvias*, &c.; from such a position they transplant with excellent roots. Similar frames are also extremely useful for *Dahlias*, for the roots, after being divided, may be planted in them, 6 inches apart, or the roots may be started in a propagating pit or frame, and transplanted to these cold frames. Sweet Peas sown in pots and boxes should be removed to cold frames after they have germinated. Stocks, Asters, Marigolds, &c., may be sown in very gentle hot-beds, that are ventilated a little day and night, and shaded from sun, for after the plants have appeared they are extremely susceptible of damp. When large enough for being pricked out singly, prepare another frame in the same way for them, prick them thereon, shade well for a few days, and eventually completely expose them, but replace the sashes in showery weather or at night, when they may be tilted up. Instead of transplanting the Stocks and Asters in frames, a wall border with a south aspect will do equally well if a few sprigs of Broom or evergreen branches are stuck in front of them; indeed, seed of these plants may be sown out-of-doors in April with satisfactory results.

Orchids.

See that the plants are kept as free from insects as possible. White scale and a minute yellow thrips are their greatest enemies. The scale will thrive alike on those from the eastern or western hemisphere, on thick fleshy-leaved plants like *Vandas*, *Saccolabiums*, or *Aërides*, as well as on the thin leaves of *Miltonias*, *Lycastes*, and *Dendrobies*; the thrips attack most frequently the thin-leaved plants, yet if allowed to get the upper hand they will do much mischief to the young leaves of *Phalænopsis*, *Saccolabiums*, or *Aërides*. They usually secrete themselves down in the heart of the plants, where no amount of fumigation that can be used with safety appears to affect them. Continual syringing will keep them in check. Some growers object to syringing overhead; but, if it is done sufficiently early in the morning to allow the plants to get dry before night, with a reduction of atmospheric moisture, no bad results will follow. For the eradication of scale nothing is more effectual than the sponge and a camel's hair brush carefully applied. Increase the temperature 6° or 8° by night, with 8° or 10° by day, according to the state of the weather. Shade with thin material during bright weather, yet never allow it to remain down when not required.

Conservatories.

These are now quite gay with early-blooming bulbous and other plants. Pots containing three or four Tulips, bordered with Club Moss, and set off in the centre with such Ferns as *Pteris serrulata*, have a beautiful effect, and the same arrangement may with advan-

tage be carried out in the case of Hyacinths. Forced shrubs are now particularly attractive, and should be mixed harmoniously with such plants as are not in flower: amongst them are Lilacs white and purple, Weigelas, Roses, Prunuses, Thorns white and scarlet, Spiræas, Deutzias, Acacias, &c. Cinerarias, Cyclamens, Zonal Pelargoniums, Chinese Primulas, Epacrises, Heaths, and Fuchsias, are also now in great beauty. Plants in general are making fresh growth, and, consequently, require more water. Prune and tie all that require such attention. Any that are in a backward condition in borders should be moved and have others put in their places. In planting from pots, loosen the ball of soil and spread out the roots, for, although this may occasion a little check for a time, the plants thrive better afterwards. All hard-wooded plants requiring re-potting should be attended to at once, and afterwards kept for a time in the closest part of the conservatory. They should not be watered for some days after being potted, but the atmosphere should, if possible, be somewhat damp. Climbers of various sorts should be thinned and tied, taking care in thinning to provide for a free display of flowers rather than a gross production of wood.

Pines.

Pay great attention to fruit swelling in all stages; continue to allow an increase of heat by day and night, as the light increases. Maintain a kindly humidity, taking care to ventilate, but so as to avoid a draught. Give tepid clear manure-water to the roots, and syringe round the stems and over the plunging materials with the same. Some charcoal, laid about the surface of the plunging material, is also beneficial in absorbing and giving off gases and humidity. Take care that such fruits as have nearly finished swelling get neither bottom watering nor syringing about the stems; and if they can be moved to a light dry situation, let it be done, in order to improve colour and flavour, and make room for others that may be starting. From those now in bloom withhold syringing for a short time till they set, and apply but moderate humidity. Give such Pines as are now starting into fruit every encouragement, in order that they may make a bold and strong appearance; taking care, at the same time, not to stint them for water at the roots. Select for another batch the finest, fittest, ripe, well-grown plants, and place them together on a well-prepared moderate bottom-heat, to come into fruit in succession, and shift on other successions to replace them. In the case of succession plants, there must be no stand-still; shift them on, as they require it, into good-sized well-drained pots, in which they are intended to fruit, using good, healthy, sweet, well-pulverised soil, charcoal, and soot. Place them on a moderate bottom-heat, increasing the atmospheric heat as light increases, which will also naturally raise the bottom-heat a little. Syringe freely now on fine afternoons, shutting up early. Maintain a kindly, humid, growing heat, and allow the plants to make full speed while there is light and heat. No check must be allowed, or splendid well-swelled fruit will not follow in succession at all seasons of the year. Starve or stagnate a young Pine plant, and it will never produce perfect fruit. Suckers, take off in succession as you clear away the fruit, and pot and start them immediately. Thus fine plants and noble well-swelled fruit will be the result. Push them along at full speed on a genial healthy bottom-heat in a humid atmosphere, well charged with ammonia, giving methodical syringings early on fine afternoons, airing freely in order to fully maintain robustness and vigour throughout their progress, and never allowing a plant to get dry at the root, or pot-bound for lack of timely re-potting. Attention to little items like these cannot fail to end in complete success.

Outdoor Fruit Department.

April, the most uncertain month in the year, makes it necessary to devote more attention than most gardeners can give to preserve their fruit blossoms from its scathing power. Apricots, Peaches, and Nectarines, will want protection as soon as the blossoms show colour. Glass coverings are certainly cheapest and best where they can be had, and strong canvas the next where it can be rolled up and down, according to the weather. All nailing and pruning should be completed as early in the month as possible, for the blossom-buds of hardy fruit trees on the walls are swelling fast. Pears on the Quince stock are usually more advanced in their buds than those on the Pear stock. The time for grafting is earlier this year than usual, and grafts intended for using must be placed in the ground behind a north wall till wanted. There are often many worthless kinds of Apples and Pears in collections, and the best way is to cut their heads off and graft them with good sorts. Gooseberry and Currant bushes will soon have their foliage expanded, unless a check comes on, and protection of some kind may save a crop should there be severe spring frosts. Fern leaves, dry hay, or Fir branches, will, if put on the top of the bushes on the appearance

of a severe night's frost often afford sufficient protection. Strawberry plantations will now want dressing, and, if a slight covering of littery manure is spread over the beds, the foliage will grow through it, as well as the flower-stalks, and the straw will keep the fruit clean. The mild season has naturally brought all kinds of orchard-house trees grown in pots into bloom sooner than usual. If the pots have not been top-dressed in the autumn they should now be done so by making a rim of fresh cut turf round the edges of the pots with the grassy side down and filling the centre with some well-rotted cow or sheep dung. This will give fresh vigour to pot-trees which have not been re-potted for years. Before the flowering process commences, syringe with Gishurst Compound of the strength of three ounces in a gallon of water, and this will help to keep the trees free from mildew and aphids; soft-soap dissolved in water of the same strength is likewise an excellent corrective of mildew on Peach, Nectarine, and Cherry trees. As soon as the stoning process in the earliest Vinery commences, a steady night and day temperature must be maintained. The thinning and stopping the shoots in the succession-houses will want frequent attention; and Muscats, when in flower, require a high temperature, 70° not being too high. To have this fine variety of Grape in the greatest perfection as regards colour and flavour, the forcing of it should be commenced in January or February if possible. The thinning the fruit in Peach-houses where too thick, and tying the shoots down as they advance in growth, must be attended to. In the earliest Peach-house it is better to leave the fruit rather thick on the trees till the stoning is over, as some may drop off then. The temperature must be kept lower till the stoning is over, the inside borders being well watered. Figs, whether grown in the borders, tubs, or pots, will require liberal waterings and syringings overhead on fine clear days. Some liquid manure may likewise be given them occasionally until they begin to ripen. Cherries require to be kept in rather a low temperature when stoning; from 50° to 55° will suit them. Air must be given freely in favourable weather. Sow now good batches of Cucumber and Melon seeds for succession-crops, and keep the young plants in the seed-beds till strong enough to harden off. The Strawberry plants placed earliest in heat will now begin to be showing colour, and watering must be more sparingly given to improve the flavour. Keens' Seedling is, if from selected plants, perhaps, the best early-forcing Strawberry yet grown, and President is also very good for a second kind for succession.

Kitchen Garden.

A golden rule to be kept in mind in reference to the kitchen garden is, to sow little, often, and thin. Thin out and otherwise attend to all growing crops. Trench every bit of ground as soon as it becomes vacant, casting it up rough and in ridges with a strong steel fork. Where necessary, give it a good dressing with manure or other compost, thoroughly incorporating it with the soil, as the trenching progresses. Care must, however, be taken, not to bring up too large a quantity of the sub-soil to the surface; but it is of great importance to loosen it well every time at the bottom of the trenches. This allows water to run through it freely, and renders it pervious to air, which is so essential to the maintenance of a healthy tilth. During mild showery weather slugs are sure to be troublesome, devouring, as they do, young vegetables, especially those in seed-beds. To prevent their ravages, sprinkle with fresh air-slaked lime. At this season saw-flies deposit their eggs on the young leaves of Gooseberries and Currants, and by-and-bye the caterpillars from these prove destructive to the crop. These may be effectually got rid of by immediately applying a thick dusting of air-slaked lime, dry soot, and dry wood-ashes, on a mild morning when the bushes are moist with dew, or after rain; or, failing the occurrence of moisture naturally, they may be damped with the garden engine or syringe. In this way, not only insects' eggs, but also Moss and Lichen, may be got rid of, and a healthy, robust, dark green appearance given to the bushes and clean stems. The weather, during the last three weeks or so, has been favourable for cropping and seed-sowing; and now, that "bright days have come again" these operations may be proceeded with. Should gaps appear amongst vegetable crops, they should be filled up from parts that are thickest, carefully preserving the roots and lifting with good balls, with a trowel in each hand. Every kind of crop may be successfully transplanted when in a young state by using hand trowels; even tap-rooted plants, such as Carrots, Parsnips, Beet, Parsley, &c., will withstand moving in this way whilst young, whilst pulling or taking up young plants, and dibbling them in with naked roots, will be found to be attended with little success. As soon as young crops appear above ground, run a light hand scarifier or an open-toothed rake across the drills, to loosen and break the surface; and, as soon as the rows can be distinguished, run a narrow Dutch hoe between them, so as to keep down weeds.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

APRIL 1.

THIS was a fair average meeting, the chief exhibitors being Messrs. George Paul, whose pot Roses were in fine condition, healthy and well-bloomed; Mr. B. S. Williams, who staged a miscellaneous collection of stove plants and Orchids; Messrs. Barr & Sugden, whose collection of cut Narcissi was a distinct feature; Mr. Smith, of Worcester, who showed a dozen variegated Acers, supposed to be new, their elegantly cut leaves being of a fine golden tint blotched with green, others red and crimson. Messrs. Veitch also had a nice collection of Orchids, Clematis, and other decorative plants. Messrs. Veitch likewise staged Clematis Duchess of Edinburgh, a fine delicate lilac variety; and John Gould Veitch, a semi-double form of a soft bluish-lilac tint; in their miscellaneous collection we may note a new species of Masdevallia, somewhat resembling *M. civilis*, and, like that species, it has a disagreeable Stapelia-like odour; also a very distinct form of *Oncidium fuscum*, with white and rosy-purple flowers; and a fine basket of the new Red Rose Duchess of Edinburgh; the new *Anthurium floribundum* was staged in this collection, it has velvety-green leaves and inconspicuous white spathes. Mr. Williams had a very interesting collection, including the new white variety of *Anthurium Scherzerianum*, here named *Williamsii*; *Ataccia cristata*, with its sombre-looking bearded inflorescence; *Ornithidium coccineum*, *Oncidium longipes*, a pretty golden-lipped variety, with dark brown sepals and petals. In addition to these were several showy Palms, Arads, and Amaryllis, the latter being very showy. A fine collection of Roses, in pots, came from Mr. George Paul. These were perfect in leaf and flower, and formed a brilliant show of themselves. Among others we may mention Annie Laxton, a fine purplish-rose; Camille de Bernardin, a well-known old favourite, most profusely flowered; Duke of Edinburgh, a fine crimson-purple variety, with stout waxy foliage; La France, fine silvery-rose; Dupuy Jamain, Princess Beatrice, and Cheshunt Hybrid, a most beautiful magenta-tinted rose; and Etienne Levet, a large rosy-lilac of fine form, with round smooth petals. In addition to the pot Roses, Messrs. George Paul and Mr. H. Bennet both staged stands of cut Roses. Mr. Goddard again staged his seedling Cyclamens, Royal Purple, Crimson Gem, and Rose Queen—for this collection Mr. Goddard was deservedly awarded a cultural certificate; and Messrs. J. Standish, Ascot, exhibited Cinerarias and early-flowering Pinks in good condition. Mr. R. Dean, of Ealing, had a group of spring-blooming Pansies and Polyanthus, very nicely bloomed. Messrs. Barr & Sugden staged a fine collection of spring-blooming Narcissi, correctly named, including forty-eight species and varieties. The Rev. W. Kendall, of East Sulworth, also staged a nice collection, which would have been still more interesting if staged singly instead of being massed in groups. Mr. Woodbridge brought cut-specimens of *Sterculia nobilis*, and the deciduous sheaths of the Bamboo Cane from Syon House. Dr. J. Denny, Stoke Newington, staged a blooming plant of his new seedling Zonal Pelargonium, Imogene; it was scarcely sufficiently advanced to judge of its truss, but the flowers are fine in form, with well-rounded petals, of a deep purplish-scarlet. Mr. J. Perkins, gardener to Lord Henniker, Thornton Hall, Suffolk, sent a fine stand of Maréchal Niel Rose, of fine form, and most beautifully coloured. J. S. Law, Esq., South Lodge, Enfield, sent two plants of *Primula verticillata* var. *sinensis*, a free-growing plant, with jagged powdery leaves, and a verticillate inflorescence of long-tubed pale-yellow flowers. Mr. E. Bennett brought pollen-bearing branches of *Cupressus Lawsoniana*, which were very beautiful.

First-class Certificates were awarded to the following:—

Boronia megastigma (Veitch).—A slender-growing plant bearing clusters of blossoms most deliciously perfumed.

Cyclamen Rose Queen (Goddard).—A fine rosy-violet form of this popular decorative plant.

Cyclamen Royal Purple (Goddard).—A fine large purple-flowered form.

Rose Duchess of Edinburgh (Bennet).—A finely formed flower of a delicate rosy-lilac tint.

Polyanthus purpureus (Dean), a deep purple form belonging to the fancy class, and a fine addition to a now popular group of hardy spring flowers.

Amaryllis Orie flame (Williams), a fine fully-expanded flower of a deep velvety-crimson colour; very effective.

Horticultural Swindlers.—Perhaps the most audacious horticultural swindlers ever known were those who for some time did a good business in France, having at one period a handsome shop in the Boulevard des Capucines at Paris. Here they had the satisfaction of swindling a large number of the aristocracy, including the Princess Mathilde, and various Marshals and Generals. In 1859 they were at Cadiz, where one acted as master, and the other took the part of servant. After doing a good business they decamped, leaving their bills unpaid, and turned up next year at Seville. When finally turned out of France, they went through Germany and the North of Europe; so lately, indeed, they were represented at Berlin, and one of them held a shop in St. Petersburg. We read of their selling a common Gentian as the *Violet de la regie*; of *Magnolia grandiflora* with blue flowers; of Cherries, three of which went to the pound; of Pinks, with fourteen colours; and Pears with four distinct flavours. Best of all, however, was the "arc-en-ciel," or rainbow, which they managed to sell to an innocent shoemaker, who did not discover until it was too late that he had only received a common Fern in exchange for his money. This wonderful plant was to produce a blue flower, from which was to issue so brilliant a light that one could see to read and write by its rays at night without the aid of any farther illumination.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSES ALL THE YEAR ROUND.

It is comparatively easy to adorn each month of the year with some form of floral beauty, and, in this way to girdle the season round with flowers enough and to spare. Still, Roses all the year round continue an exception rather than the rule. Only in gardens here and there is this feat of cultural skill attempted, and in comparatively few is it actually accomplished. Many succeed in making Roses almost as common, and even more lovely, by contrast, at least, in March than they are in June. But there is a dreary blank from November to February in most gardens, hardly lighted up by one solitary Rose-bud; and how few can say, even in the highest ranks, "My room has not been Roseless for a dozen or more years." Is it possible to have an unbroken succession of Roses? No doubt it is; for what one has done, others may accomplish. But what of the expense and appliances, number and character of houses, plants, &c., needed? Nothing to be alarmed at. Of course space, plants, and certain conveniences are requisite; and, if one could command a Rosary under glass, properly warmed, the supply of Roses all the year round would be made easy. But, without that, and with a moderate supply of, say 50, or 100, or 200 plants in pots, the year may be wreathed round with Roses. For the purpose of an uninterrupted supply, no varieties are so useful as Tea Roses; and a few of the superior varieties of Noisettes on a back wall of a greenhouse, conservatory, glass corridor, or case, are invaluable for producing fine flowers when they are most wanted. For such purposes, Adam, Gloire de Dijon, Safrano, Souvenir d'un Ami, and Madame Falcot, among the Teas; Céline Forestier, Lamarque, Maréchal Niel, and Solfaterre among Noisettes; and Souvenir de la Malmaison among Bourbons, are among the best. By so pruning and treating these, sacrificing any amount of summer and early autumnal beauty, so as to have them showing blossom freely towards the end of September (the Maréchal Niel much later, to throw flowers in January), Roses may be had in the dead season, even in as low a temperature as from 40° to 45°; if more can be given, up to 50° or 55°, there will be no difficulty. But the chief use of these Roses in cool houses is to fill up the gap between stray flowers which come late in the open air, and those which may be tempted to open their buds by a hot-bath, or the genial air of a stove or forcing-house at work. The first batch of forced Roses—perhaps the word forced should hardly be used in regard to these—for, rightly managed, they will be late rather than early Roses, the produce of plants cut sharp in about the middle or end of September, placed in a warm sunny spot, till frost threatens, and then set under glass, with a forest of buds formed or forming. A very slight heat will suffice to develop these, and many of them can hardly have too cool a treatment. A greenhouse, or conservatory shelf, will suffice to unfold their late or early beauty from November to January. A few plants of the common or dark China Rose, and the beautiful flesh-coloured Mrs. Bosanquet, the flaming scarlet Cramoise Supérieure, and the old Bourbon Queen, as well as some of the hardiest of the Teas, are the most useful for this season. About the same time as these are placed in cool houses, towards the end of October or beginning of November, a batch of Tea Roses, with plump dormant buds ready to break, and a full stream of sap prepared to bound through them, on the slightest application of more heat, should be introduced to the forcing-pit or an early Vinery or Peach-house about to start; or, lacking these, a cool stove or temperate house. These will progress rapidly in a temperature ranging from 45° to 55°, and will be in full beauty before the others have unfolded all their autumnal or winter buds. Beyond January the supply becomes easier. Towards the end of December, the first batch of hybrid perpetuals should be introduced. It may seem like a libel on our new varieties, many of which force remarkably well, but let those who are bound to have plenty of Roses, and of colours that cannot fail to please, not

neglect to provide a good stock of plants, for forcing, of those two fine old-fashioned Roses, at once brilliant, sweet, and profuse bloomers, Duchess of Sutherland and Baronne Prévost. It may almost seem like presumption to pick and choose out of this magnificent class of hybrid perpetuals, but I venture to do so for the sake of beginners, whom the following varieties will not disappoint in forcing, viz., Alfred Colomb, Antoine Ducher, Auguste Mie, Beauty of Waltham, Charles Lefebvre, Dr. Andry, Duc de Rohan, Dupuy Jamain, Eugène Appert, Exposition de Brie, General Jacqueminot, John Hopper, Jules Margottin, Le Rhone, Louise Peyronny, Madame Crapelet, Madame Julie Duran, Madame Vidot, Marie Baumann, Marie Rady, Pierre Notting, Sénateur Vaisse, Victor Verdier, and Xavier Olibo. It will be observed that most of these are dark, bright coloured pink, or red varieties. The majority of Tea Roses are yellow, orange, light, or fawn coloured; and, as a considerable collection of these is an indispensable requisite to a continuous supply of Roses, the brighter varieties of hybrid perpetuals are the more useful. Apart from this, the more delicate hybrid perpetual Roses, such as Baroness Rothschild, La France, Madame Rivers, &c., never look so pure and charming as when forced or grown under glass. Among Teas, Devonensis is a host in itself, and Madame Willermoz, Madame Margottin, Madame Bravy, Niphotos, Rubens, Souvenir d'Elise, and Belle Lyonnaise, are all very good. Among summer Roses, the common crested and white Bath Moss, the white and red Provence, Charles Lawson, Paul Ricaut, and Coupe d'Hebe are the best for forcing. None of these should be started till January or February, the later the better; and the Moss and Provence especially prove welcome additions to the other classes of Roses. After the Rose harvest comes the critical period for the plants. If every year is to have its Roses the plants must never be neglected. There must be no placing the early sorts out into the ruthless March winds as soon as the flowers are cut, no parching or starving during the summer through want of food and water; no preying of insects upon their leaves, but each class of plants must have its special course of culture to fit them to fill their own niches in the Rose season of the next year. To this end all summer labour should be sacrificed, and all summer strength and force treasured up. A warm sheltered place out of doors during summer, with proper attention to potting, staking, training, pruning, feeding with top-dressings or liquid-manure, watering, and keeping scrupulously clean is all that the Rose will require throughout the summer months. From the end of May to the end of October the outside Roses may be trusted to keep up the supply of flowers, and those in pots or planted out under glass must furnish the other seven months of the year. Of course, with a house or two filled with Tea, Noisette, Bourbon, and China Roses, a Rose harvest all the year would become a mere matter of skill in pruning or the application of heat and culture; but, in pots, more forethought and higher skill are needed to accomplish the same end. A house for Tea Roses, Mr. Rivers says, to be enjoyable should be span-roofed, glazed with large squares of glass, the rafters light, and the roof fixed. Its dimensions should be as follows:—width, 14 feet; height of sides, from 5 to 6 feet; height to ridge, from 9 to 10 feet; it should be ventilated at each side by shutters on hinges; or sashes 18 inches wide; no roof ventilation is necessary. A nicely-gravelled path, 4 feet wide, should occupy the centre, and a border made on each side 5 feet wide. Each border will hold three rows of Rose trees, which should be planted so as to form two banks of Roses in this manner—the back row should be of low standards, 3 feet in height; the middle row, standards, 2 feet 6 inches high; and the row next the path, dwarf standards, 2 feet high. When the trees are in full foliage and flower, a perfect bank of beauty is formed; for, owing to the favourable climate, the trees grow with a vigour scarcely conceivable. Previous to planting, the borders should have a dressing of manure 6 inches thick, which should be well mixed with the soil to a depth of 2 feet. In a house of this description, Tea-scented Roses will bloom beautifully from May to November; but in spring and autumn—say in May and part of June, and again in September and October—they will be in the greatest perfection. In June, July, and August, the ventilators should be closed only to exclude violent winds.

NOTES OF THE WEEK.

— ONE of the best specimens of the beautiful *Dendrobium fimbriatum oculatum*, perhaps, ever seen in this country is now in flower at Enville Hall. It is 6 feet in height, 4 feet in diameter, and is bearing sixty-four flower spikes, each averaging thirteen flowers. The latter are of a deep orange-yellow colour, the lip being much fringed, and having a deep crimson blotch in the centre.

— SIR JAMES MATHESON, of Lewis, has just intimated to the Town Council of Dingwall, his intention of presenting that burgh with a field on his property to be used as a public park, on condition that the council suitably enclose and embellish it. Sir James was, at one time, Mayor of Dingwall.

— THERE is now a very large flowered form of *Phalænopsis grandiflora* blooming in the Orchid-house at Kew. Its individual flowers are fully five inches across, and of pearly whiteness, with the exception of the yellow-blotched lip. This variety is the longest-petalled form of this beautiful plant that we remember to have seen, and, as it will be in bloom for some weeks, it is worth the inspection of cultivators.

— HYACINTHS and other spring-flowering bulbs are now blooming freely on the Thames Embankment, and also in Hyde Park. These last few warm and bright days have served to brighten up the flowers of such plants a good deal, so much so, indeed, as to make one wish they were more plentiful. Not the least attractive feature in connection with the Hyacinths is the grateful perfume diffused by them, especially in the evening.

— A PUBLIC meeting was held at Weston-super-Mare the other day, for the purpose of considering the formation of a public park and recreation grounds. The chairman, in explaining the object of the meeting, remarked that the glebe land near the church was about to be let by auction, and as no other site was so available for a pleasure park, it would be desirable to secure it. The rector had expressed his willingness to let the land to a responsible person for such a purpose as that now proposed. He concluded by proposing, "That in the opinion of this meeting it is desirable that a pleasure park be formed for the benefit of the inhabitants and visitors of this town." This was seconded and carried. A scheme for laying out the land and providing the necessary ornamental buildings, fences, and entrances, will have to be procured.

— M. FAIVRE has recently performed a series of experiments on the Mulberry, Hazel-nut, and Cherry Laurel, which he considers goes far to prove the fact that the substances which supply the food of plants have an ascending motion in the bark. For this purpose he made perfect or imperfect annular incisions through the bark, or detached pieces of the bark, to which buds were attached, or removed entire cylinders of bark from the trunk. The result of the experiments was, that the buds always continued to develop when the communication remained uninterrupted with the lower portion of the trunk; while, when this communication was completely destroyed, the buds invariably withered away. If the bud was separated by a perfect annular incision, it withered the more slowly the greater its distance from the incision; and in these cases the starch disappeared entirely from the portions of the wood above the incision between it and the bud. When entire cylinders of bark, with buds on them, were removed, the buds continued to develop, and even produced branches bearing leaves.

— IN the *Botanical Magazine*, for April, we find figures of the following plants, viz.:—*Colchicum Parkinsoni*, a native of the Greek Archipelago, and known in gardens as *C. variegatum*, *C. tessellatum*, and *C. agrippinum*; but it appears to differ from the true *C. variegatum* of Linnæus in its smaller size and more distinctly chequered or tessellated markings. This plant was originally figured and described by Parkinson, in his "*Paradisus Terrestris*," as long ago as 1629, where an excellent description of it will be found at page 156. The flowers are white, shaded with lilac and chequered with deep rose. Leaves about 6 inches long, 1½ inches broad, with revolute sinuous margins.—*Beschorneria Tonellii*, a Mexican plant, nearly related to the Agaves, having smooth unarmed bright green recurved leaves, and a nodding spike of crimson-green tipped flowers; the ovaries are of a bright purple colour.—*Aconitum heterophyllum*, a native of the Himalayas, having coarsely-lobed foliage and erect spikes or close panicles of greenish-yellow purple-tipped flowers. Although belonging to a well-known poisonous class, a preparation from this plant is extensively used as a tonic medicine throughout N. India. It is nearly allied to *A. Napellus*, a plant cultivated in cottage gardens in this country.—*Panax sambucifolius*, a warm greenhouse plant from New South Wales and Victoria, having smooth green pinnate leaves, glaucous beneath, and terminal clusters of white berries the size of large Peas.—*Epidendrum criniferum*, a native of Costa Rica. This is a slender caulescent species, with stems 12 to

15 inches high, terminated by a cluster of yellow crimson-spotted flowers, having a curious tri-lobed lip, the lateral lobes of which are lacinate or fringed, the central lobe being subulate or awl-shaped. *Rhopala Pohlil*; this plant belongs to a well-known group of free-growing Proteaceous plants, and is a native of Brazil. It is of erect habit, and has gracefully recurved pinnate foliage, like its congeners, and axillary clusters of yellow flowers.

— THE Council of the Society of Arts has decided to offer a prize, consisting of a gold medal or twenty guineas, for the best essay "On the Cultivation and Manufacture of Indian Teas."

— THE *Belgique Horticole*, for February, publishes a complete list of botanical gardens throughout the world, with the names of their curators and of the professors of botany at the different towns.

— IN Switzerland there is a law, it is said, which compels every married couple to plant six trees immediately after the ceremony, and two on the birth of every child. They are planted on commons and near the roads, and being mostly fruit trees are both useful and ornamental. The number planted amounts to 10,000 annually.

— THE Peruvian Commission have found, in Pabellon de Pica, over 6,000,000 tons of pure guano, containing a large proportion of ammonia; in the Pant de Lobos, 2,000,000 tons; in Thanibolas, 900,000 tons; in Chanabeya, 150,000 tons, all of excellent quality; at Patache, 125,000 tons; and at Patillos, 15,000 tons of inferior guano.

— THE rare and beautiful *Oncidium concolor* is now in flower in the Royal Exotic Nursery at Chelsea. Its flowers are of a clear golden-yellow colour, and are borne on a long drooping spike. This is one of the best *Oncids* in cultivation. In the same collection is also a fine mass of *Utricularia montana* in a hanging basket bearing forty fine spikes of from three to seven flower buds each. This is, we believe, the finest specimen of this plant hitherto grown in this country.

— THE large American Aloe (*Agave americana*) in the succulent house at Kew, is now throwing up a flower-spike as thick as one's arm. The plant is a very fine specimen of its kind, measuring, as it does, fully 15 feet in diameter, and the rapid-growing spike has already reached the roof. When its large candelabrum arms shall have become fully-developed it will form a conspicuous object outside the house, for room will have to be made in the roof to allow them to escape.

— THE third number of the *Illustration Horticole* contains coloured plates of *Epidendrum Catillus* (*E. Imperator* of gardens), a caulescent species having leafy stems 3 to 4 feet high, terminated by a cluster of reddish-crimson flowers. Like many other species of the same section, it continues to develop flowers for several months in succession—*Dracaena Bellula* is a slender-looking species, which if of free growth will be valuable for decorative purposes. It has recurved green foliage shaded with purple beneath and margined with crimson. *Aphelandra Facinator*—This is a stove plant of erect habit, having bright green leaves veined with broad silver bands above, and of a deep purple colour beneath. The flowers are of the most dazzling vermilion scarlet, and, contrast well with the leaves. It is one of the best plants in the whole group and comes from New Granada.

— DURING the past week we have noticed small specimens of the Cherimoyer of Peru (*Anona Cherimolia*), in Covent Garden Market. Several species of this genus are cultivated in tropical countries for the sake of their fruits. The Sour-sop of the West Indies is the fruit of *A. muricata*. It is of considerable size, often weighing upwards of 2 lbs.; it is greenish and covered with prickles, the pulp is white, and has an agreeable slightly acid flavour. The Sweet-sop is the fruit of a tree, *A. squamosa*, native of the Malay Islands, but extensively cultivated in the East and West Indies. The common Custard Apple, or Bullock's Heart, is an eatable fruit produced by *A. reticulata*, a native of the West Indies, but cultivated in the East Indies also. Its yellowish pulp is not so much relished as that of the other kinds.

— IT was announced at a recent meeting of the Académie des Sciences, that the methods adopted in the department of the Hérault for flooding the Vineyards with water strongly infiltrated with guano, has proved perfectly successful in destroying the Phylloxera, and arresting all traces of disease produced by its presence. It is reported that by the use of these guano floodings the most severely attacked plants have been restored to a healthy condition in a very short period, and have exhibited their normal vigour and productiveness. Various experiments are at present being tried in the department to ascertain the simplest and most efficacious method of employing the guano; and also to test the practicability of the schemes that have been proposed for destroying the insect by the abstraction of the oxygen from the surrounding medium; but this process, although it may be feasible in theory, is beset with almost insurmountable practical difficulties when it has to be applied to widely extended areas.

THE INDOOR GARDEN.

DICKSONIA SQUARROSA.

THIS is one of the most distinct of all the New Zealand Tree-Ferns, and one that on account of its moderate size, is well adapted for a small greenhouse or conservatory where head-room is limited. The plant is of rather slow growth, but does well in a moderately cool house. Like its congeners, it grows best in a fresh, open, peaty compost, on a thoroughly well-drained bottom, but it must be liberally supplied with moisture, and does all the better if the trunks are syringed every day during the hottest of the summer weather. As shown in the accompanying illustration, the plant is singular in habit, its fronds diverging nearly horizontally with the trunk. One of the finest examples of this choice Fern is in the collection of O. O. Wrigley, Esq., of Bridge House, Bury, Lancashire. This plant is 12 or 14 feet in height, and has a dense head of fine deep green fronds about 6 feet across. The fronds of this plant are very harsh to the touch, and, as the trunks are of a deep brown

Dicksonia squarrosa.

or black colour, they contrast well with the green colour of the fronds. It should be grown in every cool Fernery, and does best if planted out in a cool moist bed of fibrous peat and brick-rubbish. It is so distinct in habit from its congener, *D. antarctica*, that one would scarcely believe them related, except by the unmistakable characters of near resemblance afforded by the fructification. B.

FUCHSIAS ANNUALLY FROM CUTTINGS.

FUCHSIAS are such invaluable plants for conservatory decoration during the summer months that it is no wonder they are so much cultivated for that purpose. The graceful habit of growth of the plants, the profusion of bloom they yield, and their elegant blossoms, combine to render the Fuchsia one of the most popular plants cultivated in pots, and the immense quantities grown for market indicate a demand equal to the supply. It is a mistake to suppose that a high temperature is absolutely necessary to produce good specimens of Fuchsias. It is, however, of use in pushing on into rapid growth plants, which it is necessary to make into large specimens at an early

date, but it is not essential. Anyone having some bottom-heat at command in early spring, especially if it be in the form of a small stove-house, can grow fine specimen Fuchsias; and even those who have a cold house simply, can form fine plants by August if they will give them the requisite attention. If I wanted fine specimen Fuchsias, say in July and August, I should prefer to have cuttings struck last August, and grown on during the winter. It is, however, possible to have fine well-formed specimens by selecting cuttings from the earliest shoots in winter and spring put forth from the plants kept over from the previous season. The cuttings may be planted in a gentle hot-bed or in pans of sand over some bottom-heat, and they will be nicely rooted in the course of a week, and may then be potted into thumb-pots, using one half well decomposed leaf-mould and the other half a good virgin loam. Shift the plants as the pots become filled with roots, and grow them on with all speed. The Fuchsia is a rapid-growing plant, and its quick development is quite in keeping with a rude vigorous health. By the time the plants are 6 or 8 inches in length they may be removed to a warm part of a greenhouse, and kept watered and well syringed overhead in sunny warm weather. At this stage the leading shoots should be pinched out so as to induce a branching habit of growth, and in the course of three weeks or so all the other shoots should be pinched out except the leading one, which should be allowed to grow up for 6 or 8 inches, and then be again stopped, so as to keep the plant bushy at the bottom, and to induce it to form that handsome pyramidal shape, which is the most natural and fitting habit of growth for the Fuchsia. Let it be a pyramidal form, not a squat bush shape, which will sometimes happen when the main shoot is pinched back too frequently. Supposing the season to be, at this stage of the growth of the plants, about the middle or end of April, they must be syringed morning and evening, and the process of re-potting must be continued as the plants advance in growth; the points of any shoots which may be growing so strong as to endanger a symmetrical habit of growth must be kept pinched in. Do not allow the sun to shine directly on the plants; and, if the position of the house does not afford a shady spot in it, some shading should be extemporised. A dry atmosphere will beget green fly, therefore, syringe occasionally, according to the state of the weather. Should the plants show any bloom, it is well to pick it off at this stage, to throw all the strength into the growth of the plant. Supposing the cultural process has been so far followed, it may be presumed the plants will be about 2 feet in height, and of a nice regular pyramidal shape. If they are wanted for exhibition about the middle of June, the plants should not be shifted after the first week in May; the shoots should be allowed to grow, and the flowers to develop themselves freely; but stopping only sufficiently to maintain a symmetrical shape. If, on the other hand, the plants are required not for show purposes, but simply for the decoration of the conservatory during summer, the period of bloom may be retarded, so as to grow plants of a good size. If the plants are not too large to re-pot, another shift may be given at the end of May. The house in which the plants are growing should have air given it night and day, and the plants should be syringed four or five times a day, to keep the house cool and moist, and prevent the gathering of blight. It is a good plan at this stage to cover the surface of the pots with well decayed cow-manure to the depth of about 2 inches, forming it into a kind of circular trough round the rim of the pots; and, on no account, must the plants be allowed to suffer for want of water. By attending to these directions, the Fuchsias will carry good heads of bloom, and be invaluable for decorative effect.

Is it worth while holding over the plants for a second years' bloom? This is a question frequently asked by cultivators. My reply is, no, unless some very large plants are needed. The fact is, fine young vigorous plants can be grown in one season from cuttings, and, when this can be done, it is hardly worth while to be troubled with wintering old plants. Not, however, that it is difficult to winter them, but simply because cuttings make the best plants when properly grown. The old plants can be preserved through the winter by placing them under a greenhouse stage, or in any place where they can be preserved from frost. The following fine varieties

would form a good collection; they are all thoroughly approved sorts, which have been repeatedly tested:—Alpha, Avalanche (Henderson's), Arabella, Alexandrina, Delight, La Favorite, Noblesse, Starlight, Killiecrankie, Wave of Life, Weeping Beauty, and White Perfection. R. D.

LIBONIA FLORIBUNDA.

THIS plant is a native of Brazil, and was first introduced into cultivation about ten or twelve years since, by its discoverer Libon, after whom it was named. It belongs to the natural family of the Acanthaceæ, and forms a neat bush about 1½ or 2 feet high, with downy stems and branches, which are somewhat swollen at the joints. The leaves are small, oval-lance-shaped, opposite, of a fine glistening green on the upper surface, and whitish underneath. The flowers, which are very numerous, are tubular in shape, and of a scarlet colour, tipped with yellow at the mouth. They usually begin to appear in January, and the plant continues to bloom until March or April. It requires the heat of a moderately warm plant-house, and thrives in a compost of sandy loam, leaf-mould, and heath-soil. It has been objected against this plant, that it is very prone to shed its leaves unseasonably, and so becomes unsightly. This, however, may be avoided by keeping it in a steady equable temperature. If placed abruptly in a high temperature, the leaves are sure to fall. The plant is easily multiplied by cuttings struck in heat. The following mode of culture, communicated by M. Bisson to the *Revue Horticole*, is stated by him to be perfectly successful in preventing the plants from losing their leaves:—"I strike my cuttings in spring; when they are well-rooted, I plant them out, at distances of 7 or 8 inches in a well-drained bed, composed of half sand and half spent hot-bed material, and keep them covered with a frame until all danger from frost is over. I admit air by degrees, finally removing the frame altogether, and leaving the plants in the open air until the end of September, when I transplant them again into a bed of the same material, and cover them with a frame, under which I leave them for a month or six weeks, when I remove them to their permanent quarters in the plant-house, and find that they turn out equally well whether I place them in a warm house or a temperate one. Plants a year old, treated in the same way, succeed quite as well. I cut them back and prune them in before planting.

Begonia octopetala.—Of this a coloured plate has been issued, representing the flower to be white inside and red outside; but, on referring to a figure of this plant published many years ago in the *Botanical Magazine*, I found that the flower was wholly white. The re-introducers, however, assert that their figure is correctly coloured, as described to them by their collector, who saw the plant in flower and sent them the tubers, and that the reason why the flower, as figured in the *Botanical Magazine*, is altogether white, like the white variety of *Anemone japonica*, is, that having been grown, by mistake, in a stove (which this plant in nowise required and which ultimately had the effect of losing it altogether), the blossoms became bleached, and lost altogether the fine deep red under colour of petal, which they should normally have, as shown in Messrs. Fröbel's plate. This, to my mind, seems a satisfactory explanation of the discrepancy.—W. E. G., *Junior Carlton Club*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Prunus triloba.—This is one of the best of spring-flowering wall-shrubs, bearing, as it does, perfect wreaths of double pink flowers. It is even more beautiful than the double-flowered variety of *P. sinensis*, and, like that variety, is invaluable for pot-culture, either for cut flowers or for conservatory decoration, during the winter and spring months. It is sometimes called, in gardens, *Prunus Lindleyana*.—J. N. L.

Melanthus major.—This is one of the most distinct of all half-hardy foliage-plants, and one well worth growing, planted in a warm sandy border, where it forms a noble object. If planted under a south wall, and protected by a mulching of litter or dung, it stands a moderately severe winter without injury, and comes up strongly in spring. As a sub-tropical plant, in sheltered positions, it is very effective. It is easily propagated by division. Grown as a climber or pillar-plant in a cool greenhouse or winter-garden, it makes a fine plant, from 10 to 20 or more feet in height, clothed from bottom to top with large and handsome leaves.—J. H., *Sydenham*.

Dendrobium Cambridgeanum.—This lovely Orchid is just now blooming in perfection at the nurseries of Mr. James Backhouse, York. Though introduced from Assam more than twenty years ago, it has always been considered a difficult matter to bloom it well. The present Dendrobe has formed its leaves and flowers since the new year. It has been treated by Mr. Marshall in a house, the temperature of which has varied from 40° to 60°, and herein, probably, as Mr. Marshall thinks, is the secret of its throwing up its beautiful spike of bloom. The flowers are golden-orange, expanding above 3 inches in diameter. The lip, which is fringed and densely downy, has a large maroon blotch at its base, with paler pencillings below. The flowers rise in pairs from the nodes. The leaves of the plant are deep green, with a delicate purplish edging.—PETER INCHBALD, *Hovingham Lodge, York*.

THE FLOWER GARDEN.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Crustaceous Group.

Saxifraga calyciflora, of Lapeyrouse, an old Saxifrage monographist, is, for reasons that I shall explain, so far preferable to that of Gouan, which Engler adopts under the title of *S. media*, that I do not hesitate to retain the older name. Not only does it claim priority on this score, but it has a more important speciality in the fact, that in the very name *calyciflora* we have embodied one of the most marked peculiarities of the species, and one in which, so far as my knowledge extends, it stands unique. Those who have seen this plant in bloom, or, rather, in the early stages of blooming development, will recognise at once what I mean; but, as a large majority of my readers may not have had such an opportunity, seeing that the plant is somewhat rare, I must endeavour to explain more clearly what I mean. I do not think that any two adjectives will more perfectly describe the general appearance of the plant than to say that it is both hard and horny, in fact, a plant that a blind man could readily detect with his finger ends. Its rosettes are few in number, about an inch in diameter, each composed of a number of blunt-pointed spathulate leaves, of a grey colour, densely arranged in an imbricated or spiral fashion with perfect regularity, each leaf being reflexed at the point, and margined with a stiff smooth cartilaginous line. The first indication of bloom is presented by a rosy tint in the centre of one or more of these clusters of leaves, the rose gradually deepening into the most intense and lovely crimson. On close examination, it will be found that this development of colour originates in the glandular hairs that clothe the early floral leaves and the flower-stems, and cover the calyx also; its beauty may be said to culminate just as the development of the inflorescence above the rosette commences. The petals are small, more erect than expanded, and of a dirty yellowish-rose colour; in fact, of so little importance are they to the beauty of the flower, that they might be absent altogether. Hence, I think, my readers will see that as the real beauty of this plant lies in the developing inflorescence and the calyx, the specific name is essentially appropriate. It is a somewhat shy-growing plant, and not readily increased except by seeds. If grown in the rockery, it should be firmly wedged in its place by means of pieces of porous stone, as its root-hold appears to be rather slender; the same remark will equally apply to it under pot culture. The seeds, which are produced tolerably freely, do not vegetate until the second season, and grow very slowly; hence, it is advisable to remove the seedlings from the seed-pan, when very small, into a pot of fresh soil, else the Moss, which is almost sure to be developed, is apt to rot them off just at the neck. This charming Saxifrage is a native of the Pyrenees and the Italian Alps, and occurs also in Greece, in a more slender form, known as *S. calyciflora olympica*.

S. luteo-viridis.—In close relationship with the former species, but lacking the peculiar beauty of those crimson glandular hairs that I have described, this species so named, and most appropriately so, by Schott and Kotschy, possesses much smaller rosettes and so far elongated that its leaf development extends along the densely-arranged branches; small and hard in texture, the whole forming a dense compact mass, from which the flower-stems, clothed with numerous linear leaves and furnished with green glandular hairs, rise some 2 or 3 inches, each stem being terminated by a few flowers of a yellowish-green colour; hence its specific name. The cultural remarks apply equally to this as to the last, except that *luteo-viridis* is rather a freer grower, and more readily increased by division, but still it is by no means a common plant in cultivation. It is a native of the Caucasus and Armenian Mountains.

S. cæsia of Linnæus is a gem of the first water; its height, as regards foliage, can only be measured by fractional parts of an inch; its rosettes are about a quarter of an inch in diameter, beautifully arranged, like a microscopic bit of tessellated pavement, each so perfectly and evenly developed as to be an exact counterpart of its neighbour. The leaves are somewhat sharply pointed and recurved one on the other; the beauty of their regular arrangement being enhanced by the minute specks of white crustaceous matter with which they are dotted; the flower-stems are erect, slender, covered with a dense dark glandular pubescence, and terminated by three to six pure white flowers, of a development that must be looked upon as large, when compared with the rosettes from whence they spring; they are produced in the month of July, thus extending the period of blooming in the Saxifrages even beyond Midsummer; so beautiful, however, is the plant, independent of the flowers, that it would be no harm even if they were omitted altogether. In cultivation, I find that a mixture of peat soil and silver-sand, in a proportion of two-thirds of the former to one-third of the latter, with a few nodules of limestone

intermixed, suits it admirably; and, if planted in a rockery, this special provision, as regards soil, should be made, if success is to be attained; in ordinary soil it turns sickly and yellow, and ultimately collapses. It has a wide geographical range, extending from the Pyrenees through the whole of the lower spurs of the central European Alps, where it is found growing in dense patches, firmly embedded in the crevices of limestone rocks. No collection of Saxifrages should be considered complete till this desirable species is added to it.

S. squarrosa.—If I have ascribed a beauty of a minute character, all the more beautiful on account of its minuteness, to the last-named species, I must characterise the present as microscopic. Harder and more woody in texture, its tiny rosettes consist of six or eight leaves, broad at the base, and somewhat deltoid in form, not recurved, as in the preceding, but more rigid and erect, each leaf towards the apex being margined with a few crustaceous markings; so dwarf and dense, in fact, is this plant, that it might readily be taken for some form of Lichen that, growing out of the stone, had become, in its structural character, assimilated to the stone itself. The first acquaintance I made with this plant was at Mr. Maw's last autumn, where nice patches were being established, and, indeed, appeared to have suffered nothing from a fortnight's confinement in the interior of a vasculum while being conveyed from the Maritime Alps to the Severn valley. From its extreme minuteness, it is one of those plants that require the sharp eagle eye of a thorough botanical collector to detect; hence, no doubt, the reason why it has not made its appearance in general cultivation before. Both *squarrosa* and *cæsia* should have full and complete exposure, and thorough drainage, whether grown in the rockery or in pots; if in the former, they ought to be placed at a height sufficient to bring them close under the eye, else their minute beauties are apt to be overlooked.

S. valdensis of De Candolle derives its specific name from the Valley of the Valdini, in the Savoy Alps, where the plants from which it was first described were found. This, along with the two following species, must be looked upon as connected with their more truly crustaceous brethren, by their hardness of texture rather than by any special markings, and also by the character of the flowers. The growth of our present species is as distinctly marked by irregularity in outline as that of the two previous species was by regularity. Its little fleshy grey leaves are arranged in tufted irregularly-branching rosettes; their blunt points, crowned with a white tip, are erect and slightly expanding, the whole forming a compact dense mass, from the more prominent of whose rosettes arise the flower-stalks, to a height of about 2 inches, clothed with short glandular hairs, and crowned with three or four white flowers of great purity. It is a tolerably free grower, as compared with others of the hard horny type, and should always be provided with some mechanical means to give it a firm root-hold, such as small fragments of stone incorporated with the soil will always afford.

S. diapsenioides.—As its specific title indicates, bears a striking similitude to the charming little *Diapsensia* of northern latitudes. It is a species that has been in cultivation in this country for a good many years, but, owing to its remarkably slow growth and hard texture, it does not increase freely, in fact, the attempt at division is attended with great risk, so long as the tuft retains its compactness, but occasionally it becomes naturally broken up. When it assumes this character, the process of division may be readily and safely accomplished. It has many characteristics in general appearance with *valdensis*, but its leaves are narrower, almost triquetrous, sharp-pointed, and its little rosettes appear to indulge in a lateral, rather than an erect, growth. Its flower-stems are about 2 inches in height, usually supporting three flowers each. The bracts are large, membranous, tipped with rose, and the stem and calyxes are suffused with the same tint, rendered beautifully soft in appearance by the glandular pubescence that accompanies it. The individual flowers are above a quarter of an inch in diameter; they expand quite flat, and have an even and circular outline, the colour being pure white. The size of the flowers are in striking contrast to the diminutive growth of the plant. It is a native of the Maritime and Swiss and Tyrolean Alps.

S. aretioides derives its specific title from its resemblance to the Primulaceous genus *Aretia*, to which, both in the matter of foliage and the colour of the flowers it has a great similarity. In size about the same, and in hardness of texture also, it claims a close affinity to *valdensis*, but its leaves are narrower, more sharply pointed, and of a dark green, thus showing off to advantage the white crustaceous mark that occurs at the extremity of each tiny leaf. It is, however, in the flowers that the most important distinction rests; these are yellow with the slightest tinge of green therein, and are usually produced solitary or in pairs, on a foot-stalk not more than an inch high. Like all the others, it is of but slow growth, a good-sized patch representing the growth of years; it seeds pretty freely,

but requires great attention to get the delicate little plantlets through the early stages of their development. Geographically speaking, it appears to be almost confined to the western and central Pyrenees, where it grows in considerable abundance. For many years *S. sedoides* was cultivated under this title, and, I believe, to Messrs. Backhouse belongs the credit for having first introduced us to the true plant.

S. mutata of Linnæus, and **S. florulenta** of Moretti, ought perhaps to have taken a position earlier on in the present group, but had I done so they would have made a break in the gradually diminishing series that I have enumerated from *Cotyledon* on the one hand to *squarrosa* on the other, so I thought it better to reserve them as the concluding species of the crustaceous section; correctly speaking, they form a brace by themselves, possessing as they do a largely-developed cartilaginous margin, smooth in the former, and serrated in the latter, devoid of those white markings which constitute the all-important character of this group. Another peculiarity they have in common is, that however long it may take to acquire the necessary development of rosette, the process of flowering and ripening the seed is immediately followed by the death of the parent; neither species appears to have any power of developing off-shoots from the base, thus giving them a somewhat biennial character; albeit I have a strong suspicion that in the case of *florulenta*, the preparatory stages before blooming may extend over ten or twelve, or even more, years, judging by the quantity of old decayed leaves that subtend the vitally active portion of the rosette. In the foregoing remarks, I think I have established sufficient grounds to justify myself in considering them as accessories rather than as actually belonging to this group. *S. mutata* has a great resemblance, in outward appearance, to *lingulata*; the radical leaves are broader, and blunt, or, in fact, rounded at the point; the rosette is more perfect in its form, and, prior to flowering, assumes a cup-shaped character; the inflorescence rises to a height of 15 inches or more, is densely covered with glandular hairs through its whole extent; the cauline leaves are abundant, gradually becoming narrower, and ultimately forming linear bracts through the entire inflorescence; the petals are somewhat narrow, of a yellowish-buff colour, scarcely as long as the calycine segments; the flowers are, however, dense and pyramidal in their arrangement, which adds much to the generally effective appearance of the plant. Seeing that the immortal Linnæus has stood sponsor for the name, it will at once be patent that this species of Saxifrage is no modern introduction; and yet, between the years 1850 and 1872, I have endeavoured in vain to get a plant of it. In the former year, I flowered a number of plants raised from Swiss seed; in the latter, I flowered a plant that had come by chance—a seedling, whence I know not; but, after some three years' growth, it bloomed, and proved itself, as I suspected, the true *mutata*. It is not a little singular that a plant possessing, if not real beauty—at least all those elements of interest that will at once arrest the attention of even the casual observer—should, for such a long period, be almost unknown in this country, the more so, considering that it is by no means confined to a limited area in its natural locations, but is found abundantly on the Pyrenees, the Alps, and, in fact, all the mountains of central Europe. Within the last five months, I have been called upon to name collections of plants brought home from Switzerland by amateur tourists, and in every case this identical Saxifrage has been the most abundant form; looking at it from a cultural point of view, it is a plant that requires, when in bloom, a free and abundant supply of moisture, without which the death of the plant occurs before the blooming process is complete, and, as a result, the seeds, though partially developed, are imperfect. Such was my case in the year 1850.

S. florulenta.—Though found, named, and described by Moretti as collected by him in the Col de Madonna many years ago, has, till within the last two years, never got into cultivation, nor, indeed, is it to be met with even in herbaria. This is all the more astonishing, seeing that, in point of beauty, it is a far more desirable species than the former. The radical leaves of this plant are narrow and lanceolate, forming a dense rosette of considerable size, and, if I may judge by the number of old and decayed leaves that I have had to remove previous to potting some plants that came into my hands some two years ago, I think I cannot be far wrong in estimating their age at not much less than ten years, if not more; the leaves have a smooth cartilaginous margin towards the point, the base being lined with fine ciliary serratures. The inflorescence, like the former species, is dense, and covered in all its parts with glandular hairs. The petals are of a rose colour, somewhat narrow, but, in the mass, presenting a very effective appearance, sufficient, at least, to dignify it, according to Moretti, as “a splendid plant.” Knowing, as I have done, this species by description, I have often wondered how a plant, so markedly distinct, and, at the same time, effective should in these days of Alpine clubs and Alpine travellers, continue

to be known only by name. The mystery, however, was solved last autumn, when on a visit to Mr. Maw, of Benthall Hall—he had then just returned from a tour to the Maritime Alps laden with botanical spoils, and amongst these were numbers of plants of *S. florulenta*, varying in size from 2 to almost 6 inches in diameter of the rosettes; these were from a new locality, or, I ought to say, new localities, having been collected in the Col du Fenestrelle and the Col du Cerise, to quote Mr. Maw's own words, "both near the watershed of the Maritime Alps, between the valleys of Lantosca and Valdini," whence then, it may be asked, arises the rarity of a plant that grows in abundance in a region tolerably well frequented by our tourists? Mr. Maw's explanation at once solves this enigma. He informed me, that his attention was first attracted to masses of decayed leaves that lay scattered about on the loose snow that subtends the line of perpetual snow; on examining them, he found that they were the dead flower-stems of the plant he was in quest of—and, as the fact of their occurrence here, at once indicated that the plants must be looked for higher up—a scramble over the uninviting snow debris soon revealed the true habitat of *florulenta*; there it was, growing in abundance in the fissures that occur in the face of the perpendicular rocks, just below the permanent snow-line, and, of this fact, let the Saxifrage-grower make a special note, for if he wishes to succeed, he must take a lesson from the book of nature. This species will, I understand, be figured in an early number of the *Botanical Magazine*, where, no doubt, it will be supplemented by some remarks from the pen of its discoverer, Mr. Maw.

In thus completing the enumeration of the species that form the crustaceous group, I may state, that I have confined my remarks to those only in cultivation; there are many other species of equal beauty, which, at present, we know only by description; but, with which, we trust, our Alpine tourist friends will, ere long, give us an opportunity of forming a personal acquaintance.

IRISES.

THAN the different species of Iris few plants are more beautiful. "Iris of all hues," says Milton, and other writers have compared their colours to those of the rainbow. With the exception of the Rose, no flower has been more celebrated both by historians and poets than this genus of plants. It is also a great recommendation to the different species of Iris that, whilst some of them blossom early, others succeed them all through the earlier summer months, and onwards until July. Old writers dwell with delight on the rich and varied colours of the Iris, which they were anxious, like ourselves, to see flourishing in every garden, not only in borders but even in water; for, says Scott—

Where waves the Bulrush as the waters glide,
The yellow flag-flowers deck the sunny side.

and it is difficult to imagine an effect more agreeable to the eye than to see clumps of these yellow flowers reflected on the clear waters of our streams and ornamental lakes. Even in situations in which it might be desirable to keep the waters themselves free from aquatic, there can be no objection to having the banks beautified by yellow and purple Irises, provided they are planted in a natural and tasteful way, all appearance of art being concealed as much as possible. While the yellow Iris may be set in the water, the purple sort should be placed on the bank by way of contrast—not in any regular way, however, but here and there in masses. In borders, the dwarf kinds of Iris cannot fail to be attractive. The Persian Iris flowers as early as February and March, but it likes a sheltered border and a warm soil. Then there is the dwarf Iris (*I. pumila*), also a kind which flowers in spring, and coming, as it does, from the open hills of Austria and Hungary, it endures the inclemency of our winters without injury. For the decoration of rock-work, or for the margins of borders, this is a useful kind. It might be planted among Primroses, Narcissi, or other early-flowering plants, among which it might be desirable to get a purple contrast. Of the singular and really beautiful Chalcedonian Iris (*I. susiana*), I have seen fine plants in flower in Covent Garden. Its flowers are very large, densely spotted, and striped with dark purple on a grey ground. This is a kind which has been cultivated in gardens ever since the fifteenth century. Gerard tells us that it flourished well in his garden, being planted in ground that was not over wet. He also says that "the whole flower is the colour of a ginnie hen—a rare and beautiful flower to behold." The Florentine Iris is another desirable kind, which blooms early in May. Its flowers are white slightly tinged with blue, and it has a bright yellow beard. Its roots when dried give out an agreeable perfume, somewhat similar to that of Violets; it is, in fact, the Orris root of the shops. *Iris pallida* is a tall fine species, which produces pale blue flowers early in the summer. *Iris ochroleuca* is also a tall distinct-looking sort, and of the larger

violet German Iris too many can scarcely be about any place. Of this there are innumerable varieties, all of which are likewise well worth growing. *Iris graminea* is a pretty kind, intermediate in stature between the dwarf and tall varieties; its flowers are violet-lilac veined with blue, with a yellow band in the middle. *Iris sibirica* is a distinct kind, which thrives in marshy soil; and, lastly, there is the lovely *Iris reticulata*, a perfect gem in its way, and well worth growing wherever there is a warm nook in which to put it. Its colours are extremely beautiful, and its flowers are produced in sufficient abundance to render them effective and striking. It blooms in the greatest perfection all through the months of March and April, the golden-yellow blotched lip setting off the brilliant purplish-blue flowers to excellent advantage. For spring border decoration it must be regarded as a great acquisition; it is very dwarf, scarcely rising more than 6 inches in height, and it is perfectly hardy. A light peaty soil suits it best. The Mount Lebanon Iris (*I. Histrio*) is a very beautiful early-flowering species, opening its rich blue-speckled flowers in January, on a warm south border. It belongs to the bulbous section, and deserves to be grown on account of its early-blooming habit and showy flowers. It is a native of the Holy Land, being found in tolerable abundance in several parts of Palestine, more especially on Mount Lebanon, where its lovely purplish-blue blossoms peep through the herbage in company with long slender green leaves.

TWEEDSIDE.

Seed Ripening on Cut Flowers.—An exceedingly curious and interesting botanical specimen was submitted to the inspection of the floral committee of the Royal Horticultural Society at its meeting on the 1st. inst. It consisted of a branch of *Berberis japonica*, which had been cut from that shrub at the commencement of the month of February when in full bloom, and placed in a bottle of water, in which it had continued to produce and expand its deliciously sweet-scented blossoms of a pale green colour, up to the tops of the flower-spikes, for a period of over a month after having been cut, and had then produced and perfected a number of berries amounting to three or four at the base of each flower-stem and when cut open they showed perfectly formed seeds. This is the more singular as this shrub, though very free-flowering, seldom produces any seed berries when left to itself. In connection with this fact, Mr. A. Salter informed the committee that nearly all the *Chrysanthemum* seed from which he and his father, Mr. J. Salter, of the Versailles Nursery, Hammersmith, raised the many fine varieties of this valuable winter-blooming flower, for which they became so justly celebrated, was ripened by them on carefully crossed and hybridised flower-heads cut from the plant, and placed in jars of water, where they often took three months to ripen their seed, but in almost every instance did ripen it, perfectly and thoroughly; a circumstance which could not be depended on, if the stems were left on the plants, where they usually damped off without ripening any seed.

—W. E. G.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Clay Edgings at Battersea.—How are those clay edgings, if I may so call them, that surround the carpet beds in Battersea Park and elsewhere, made, and of what do they consist? I mean those in which the *Echeverias* and *Semprevivums* are planted.—J. S. S., *Newmarket*. [These clay rims are very ugly. They are made of cow-dung and loam, worked with water into a paste, and put into form by means of a trowel.]

Keteleer's Larkspur (*Delphinium Keteleerii*).—Can you give me any information about this Larkspur?—J. MORRISON. [A coloured illustration of it is given in the *Florist* for this month. It is a hardy perennial, the blossoms of which are borne in dense spikes nearly a foot long; they are double, about 1½ inches across, and bright blue, with a white eye in a pink setting. Grown well it cannot fail to be effective.—ED.]

***Veratrum nigrum*.**—This old and well-known plant is now a conspicuous object on one of the herbaceous borders at Kew. Its foliage is broad, and of a bright green colour, each leaf being folded or plaited, like the foliage of some Palms. These leaves are quite a foot long, and about 6 inches wide, and the plant is now far more ornamental than later in the season when in bloom. Its fine fresh green leaves entitle it to a place in every herbaceous border.—B. J.

The Bromelia-leaved Sea Holly (*Eryngium bromeliæfolium*).—This has stood several winters with me, fully exposed, without shelter of any kind, the foliage remaining green the whole winter, and this neighbourhood is not favourable to plants of a tender character. In the same border, and near it, is another plant generally regarded as tender, which also proves quite hardy here, viz., *Leucocarpus alatus*, but it does not fruit so freely as when the roots are cramped in pots. It is, of course, cut down in the autumn, but breaks out vigorously again in the spring.—J. M., *Hawkechurch, near Arminster, Devon*.

High-coloured Hybrid Primroses.—In the spring of 1873 I crossed the mauve-coloured *Primula altaica* with *P. vulgaris auriculiflora*, and succeeded in raising some seedlings, which have bloomed this spring for the first time. My object was to get more colour into the *P. altaica*, and also infuse into the progeny the fine thrum-eyed centre characteristic of the pollen parent. The result has proved most satisfactory. In all the seedlings the flowers are very large and stout, and of varying hues of rosy-violet, and in most cases thrum-eyed. These seedlings having been much admired, I have made other crosses this season, and hope to realise the best results from them.—R. D.

THE GARDEN IN THE HOUSE.

ORNAMENTAL PLANT STANDS.

WHEREVER plants are used for the decoration of the drawing-room or front hall, stands of some kind must be employed, and, when well designed, they do much towards showing off the plants effectively. Wire stands show the pots very plainly through their sides, and, unless a pan is set inside them, the water runs through on to the carpet. The accompanying is an illustration of a stand, which, when made of varnished Pine, harmonises well with the furniture of a drawing-room, library, or front hall, and sets off the plants to advantage. The sides are neatly moulded, and made high enough to hide the pots in which the plants are grown; and these sides, as well as the bottom, instead of being painted, are well coated with Japan varnish, which protects the wood and carpet quite as well as if a tray of lead or zinc were set inside. When plants are nicely arranged on stands such as this, the latter are far more ornamental than those made of wire. In the arrangement, select a bold and effective plant for the centre, as, for instance, a *Dracæna* or a *Ficus*, which always look well surrounded by Ferns, small Palms, Begonias, and trailing or gracefully drooping plants, as *Tradescantia*, *Panicum variegatum*, *Creeping Jenny* (*Lysimachia*), or *Selaginellas*. For edging these stands, either *Festuca glauca* or *Isolepis (pygmæa) gracilis* may be employed, and always look well; or a few succulents may be added for the sake of variety. The Royal Horticultural Society last year offered prizes for the best arranged plant stands of this description, and some nice arrangements were the result, but this year we hope to see still greater variety. It must be remembered that nearly as much depends on the shape of the stands as on the plants used, and it is easier to satisfy oneself when the stand is a pretty one, and shows off the plants well, than when we have to hide its unsightliness as much as possible by means of the graceful forms of plants. In filling stands like the above, all crowding must be avoided, and as much variety obtained as possible, always remembering to vary form as well as colour. During the early months of the year, they may be filled with spring flowers and bulbs in pots, and, by the use of these, as they bloom in succession, a pleasing variety may be maintained for several weeks, and, with the addition of a few distinct Palms or graceful Ferns, will make very effective arrangements.

SMALL VASES OF FLOWERS.

A SHORT time ago, when paying a visit to a friend, I was struck with the arrangement of two small vases of flowers, which stood on a side table, and, being particularly effective, I shall endeavour to describe them. The shape of the vases, if I may so term them, was that of the low-sized Hyacinth glasses, gold pattern on an opaque ground. Their contents consisted of *Deutzias*, *Azaleas*, sweet-scented *Geranium* leaves, pink *Cape Heaths*, and several bunches of blue *Forget-me-nots*, arranged in

the following manner. The foundation, if I may so call it, of the bouquets consisted of large bunches of *Deutzias*, not full blown, only in bud, and, through these were interspersed the other flowers just mentioned, the pink and blue coming out well against the white and green. On my return home, having several large plants of *Deutzia* in flower, I thought I would arrange a little stand myself. Not having a stand of the shape just referred to I selected a china hand holding a vase. Like my friend, I made the foundation of *Deutzias*, but not having any of the other flowers named, I used in their places, *Lily of the Valley*, a few sprays of a rich purple-coloured *Cineraria* with a white centre, some leaves of *Lady Plymouth Geranium*, and three fronds of *Maiden-hair Fern*. This arrangement looked very effective by daylight, but I quite expected to see its beauty vanish when subjected to artificial light, as it is generally supposed that violet and mauve shades are ineffective, when placed under gas light. In this instance, I was however, agreeably surprised to find that the purple of the *Cineraria* looked, if any-

thing, richer than when seen by daylight. I have seen a mauve-coloured *Cyclamen* look well by gas light, but I never for a moment supposed that the dark shade of the *Cineraria* would show up so well. As a rule, it is much better, when arranging flowers to select those that look well both by day and gas light, as one cannot have two sets of vases, and sometimes flowers that look well when being arranged have a sadly different appearance under artificial light; now, when summer is at hand, however, this matter becomes of less importance, as, of course, they will be seen nearly altogether by daylight. A small specimen glass which I saw the other day filled with *Lily of the Valley*, *Pinks*, *Hepaticas*, and a few fronds of *Maiden-hair Fern*, had a fine effect. The *Lily of the Valley* was first placed in the glass, and arranged so as to droop round gracefully, dotted through it the *Hepaticas* and the *Maiden-hair* were so placed as to form a kind of fan of foliage at the back.

A. HASSARD.

Upper Norwood.

A useful Plant Stand.

IMANTOPHYLLUM MINIATUM.

ONE of your correspondents speaks of this as an excellent subject for greenhouse or conservatory decoration, an observation

with which I quite agree, and I may add that I have found it to be the best plant that has yet come under my notice for dwelling-room ornamentation. There are many plants which thrive moderately well in such positions during part of the season, and then require others to be substituted for them, while they are removed to more genial quarters, in order to re-establish themselves; and there are others which succeed in such positions continuously, if well cared for; but the *Imantophyllum miniatum* grows and flowers beautifully indoors; in fact, thrives with me under positive neglect. I have now a plant of it in a 32-sized pot, bearing eleven perfectly-formed flowers, as fine as any I ever saw produced by this plant, even in a greenhouse, and it has been in my house, in the same pot, eighteen months; sometimes it has been without water two and three months together, and with dust enough on the foliage to kill most plants; sometimes it has been on the floor between my desk and the window, the window being 3 feet above it; at other

times it has stood in a corner behind a door, where it got water only when some one took pity on it. Yet, in spite of all this, its foliage is in perfect condition, and I now look upon the plant in my window as a real gem. Last season, at this time, I had a large plant of this *Imantophyllum* which, though similarly treated, threw up six strong well-developed flower scapes, and opened its blossoms most satisfactorily. J. CROUCHER.

Mounting Ferns.—By taking a little trouble, pretty pictures may often be made out of many Fern fronds, considered useless in the greenhouse, or, at all events, by the use of a few which may be cut off, and never missed. After the Ferns have been removed, they should be dried between sheets of botanical drying paper; even old newspapers or blotting paper will answer the purpose. Presuming that a collection of dried Ferns is at hand, a sheet of nice cardboard should be procured; some like white cardboard; I prefer it slightly tinted, but that is quite a matter of taste. The Ferns should then be laid lightly on it, and arranged in the form of a bouquet, or in whatever shape desired. The position of each Fern should be indicated before it is glued down, as, after that, it could not be well removed without marking the cardboard. Supposing the fronds to have been arranged according to taste, they should be lifted up again, and their backs should be glued with a fine brush, so as to make them stick to the paper. Should any gold or silver varieties be amongst those selected, they should be placed so as to show the colour of the under sides of the fronds. The light-coloured Moss, which is to be found growing on old trunks of trees, if interspersed through the Ferns, tends to give the arrangement a light and elegant appearance. A wreath of Ferns, mounted in this way, has an effective appearance, if placed round or under a handsomely illuminated text. The fronds selected for mounting in this way should be those of small and light-looking varieties, as large and heavy-growing fronds would make a small arrangement of this description look heavy. In this way a capital book of reference on Ferns might be made up, each variety being mounted on a sheet of drawing-paper or cardboard, and the name of the variety, height of growth, native country, &c., written under the frond. It will be found astonishing how very quickly a collection of this kind can be got up, as single fronds are easily obtained.—A. HASSARD, *Upper Norwood*.

House Plants.—Perhaps every one is not aware that the coldest place in a room, on a cloudy day or at night, is within a foot or so of the window, just where the plant-stand is stationed. All dwellings cannot be new, and new ones are not always proof against the insidious attacks of cold. In the old ones the windows become loose with the wear and tear of years; there are cracks and crevices where a small current of cold air penetrates, and where the frost creeps in stealthily and seizes on the green leaves. To guard against this, I paste a narrow strip of paper (of a colour corresponding with the paint in the room) over every aperture that admits a passage for the air from without. The unsoiled margin of newspapers is very good for this purpose, as the texture is light and thin, and adheres readily to the wood. Every one, I presume, does not know what an amount of cold a thin piece of paper is capable of keeping out. Give it a trial and prove the fact, only do not select a cold freezing day for the business. It saves the trouble of moving the plants at night, and ensures their safety when the mercury drops low in the thermometer. Our climate is subject to sudden and unlooked-for changes, and often one night will destroy a whole winter's care, and ruin hopeful prospects, even as late as March, when we deem our security good. It is well to be prepared for these emergencies or caprices of our latitude. Some complain of their plants growing spindling and weak, and yielding no bloom. One fault is too high a temperature, with too much water, a portion of the time, during the day, and too low a one at night. When this is the case they grow sickly, and we hear the often-repeated complaint, "I can't keep plants, they don't do well; what do you do to yours?" You want strong yet growthy plants to secure bloom and beauty. Every day, when I water, I turn my plants, and thus keep them even and shapely, by allowing every side the advantage of the sun. A slip will grow during the winter and become a large flowering plant in a 4-inch pot, if judiciously watered and cared for. Earthen pots, without glaze, are best, as they are porous, and absorb superfluous moisture.

Flowers in Sand.—Many pretty little blossoms of bulbs of Violets, Primroses, and other spring flowers having short stalks, will keep fresh for a long time, if each flower be pricked into a saucer or plate of wet sand. The great advantage of the sand over water used in the usual way is that each bloom remains in its place just where fixed. I always keep a flat glass dish, filled as stated above, on my side-board, and as the flowers decay, I remove them, and stick in a few more in their places.—N. T. O.

THE ARBORETUM.

SPRING-FLOWERING SHRUBS.

DURING the first warm days of spring, few objects are more effective than flowering trees and shrubs for brightening up our gardens and pleasure-grounds. No matter what natural advantages a garden may possess, it generally looks bare during the earlier portion of the year, unless well stocked with early-flowering trees, shrubs, and flowers. These are permanent in their character, and, if judiciously grouped with evergreens, they play an important part in making our gardens enjoyable during the first months of the year. We are acquainted with many large gardens which never look so well as in spring, when early-flowering shrubs are in bloom. Among those at present in flower we may allude more particularly to the common Furze or Whin (*Ulex europæus*), which is, at present, an object of great beauty on many of the commons and open places around London. It does best on a warm dry soil, fully exposed to the sun, and, when grown in such positions, it blooms all through the winter months, lighting up the margins of shrubberies or sloping banks with bright golden blossoms. In out-of-the-way places and on dry rocky banks few plants do better than this and its double-flowered variety. The single form is easily raised from seeds, which may be sown as soon as ripe in the places where the plants are to remain. Another yellow-blossomed plant, blooming at the same time as the Furze, is the Golden Jessamine (*J. nudiflorum*), one of the prettiest of all wall plants, especially when associated with Ivy or other evergreen climbers, the foliage of which sets its flowers off to excellent advantage. Following the Jessamine we have *Forsythia viridissima* and *F. suspensa*, both of which are now blooming freely, either in the form of bush-plants in the shrubberies or in the shape of trellis-plants. Some years ago I planted *Forsythia suspensa* and the red-flowering Currant (*Ribes sanguineum*) alternately along a trellis in my garden, and just now (April 5th) they form a perfect wall of bright rosy and yellow flowers, which contrast well with the fresh green leaf-buds that are now just bursting from their wintry coverings. The common purple Mezereon and its white-flowered form are also nice additions to spring-blooming shrubs, and even the common Spurge Laurel (*Daphne Laureola*) is a pretty object when thickly studded with light green sweet-scented flowers. Of all the hardy shrubs, however, worth a place in our gardens the foremost rank must be assigned to *Magnolia Soulangeana*, which is one of the finest of all of them. It blooms in March on a warm sunny wall, and generally a fortnight later, if planted out on the open lawn. My plants are this year covered with fine flowers, and, on passing the Wandsworth Road Station the other day I saw three specimens of this *Magnolia* covered with an abundant crop of purple-tinted sweetly-scented flowers. The latter are nearly as large as those of the white-flowered *M. grandiflora*, but this *Magnolia* differs from *M. grandiflora* in being deciduous, and its purple-tinted flowers are borne before the leaves appear. For walls, one of the prettiest of all shrubs is *Cydonia japonica*, which is just now one mass of crimson blossoms. Its pale-coloured variety is well worth growing by way of change, and as wall-plants both kinds have few equals. One of the most distinct and beautiful of spring-flowering shrubs, however, is *Berberis Darwinii*, which should occupy a place in every garden, however small. Just now, we have bushes of this *Berberis* literally laden with brilliant rich orange flowers, and its leaves, although small, are numerous, and of the deepest and most glossy green imaginable. Either as isolated specimens, or, as a hedge-plant, this *Berberis* deserves general cultivation. One of the best white-flowering shrubs we have, and one which forms a charming companion to the *Berberis* just named is the *Laurustinus*, which is just now one mass of snowy blossoms in many gardens around London. Apart from its dwarf habit and profuse-flowering qualities when grown out of doors, it deserves to be largely grown for forcing purposes. Plants taken up from shrubbery borders, and potted in any good garden soil, form nice specimens for the conservatory during February and March, and its dense clusters of snow-white flowers come in usefully as cut bloom. Some of the early-

blooming Rhododendrons are now brightening up our gardens in warm sheltered localities, and the Almond trees are in most cases covered with flowers. *Prunus triloba* is a showy wall-plant, its branches being so thickly covered with little rosette-like pink flowers, that they may almost be likened to wreaths, beset with miniature pure white Roses. Its double-blossomed congener, too, *P. sinensis*, is, if possible, still more beautiful. Both may easily be grown in pots, and then form nice plants for conservatory decoration; especially the last, the snowy flowers of which are very beautiful, either in button-holes or bouquets. Others might be enumerated; but these include the best and most generally useful of early-flowering hardy shrubs.

SEA-SIDE PLANTING.

IN reply to "Salmoniceps's" observations in reference to this subject (see p. 274), I beg to say that the three Conifers which he recommends have been tried in a stormy locality, and have been found wanting; the whole of the plants died, as did most of those of *Pinus insignis*, but it was not the stormy place that killed them so much as the clay soil in which they were planted, and which was too much for them. Conifers, in general, are not partial to strong blue clays, and, although they will thrive close down to the water's edge where the soil is light and sandy, they cut a sorry figure when the clay is such as it is at Greenhill, Weymouth. So much for the Conifers. Now, as to the *Camellia*. I only planted two of these as trial plants, and, when I last examined them, just after a storm, every leaf was intact, and they looked as hardy as *Buckthorn* close by them; they were not in the least protected, and were purposely planted as near to the water, and as much exposed as possible. As to *Escallonia* and *Mahonia*, I found them all right, as well as *Picea pectinata* and *Nordmanniana*, only this last had its leaves browned on the seaward side. I ought, perhaps, to have been more particular about *Rhododendrons*, as I only tried *R. hirsutum*, which did well; but, when I mentioned the above plants, I had in my mind's eye a splendid group of them close by the sea at Bournemouth, where the soil is congenial to them; and, whilst speaking of Bournemouth, I may mention a very large and handsome *Camellia* there, at least 10 feet high and nearly as much through, which seems quite at home in that quarter, and has been so for several years, within 100 yards of the sea. I, also, may mention some splendid *Araucarias* at Branksome Dale, where they are planted in large numbers within short distances of a stormy coast. Here, however, the soil suits them, and the blue clay may not continue to do so at Weymouth. As regards the *Horse Chestnut*, it was not planted at Greenhill; but there are fine young trees of it, situated on high and stormy ground, at Rodwell, and exposed to the sou'westers across Chissel Beach. *Beech*, *Sycamores*, and *Willows* are, as your correspondent says, good sea-side trees; and to these I may add *Hornbeam* and *Elder*, and one of the most persistent sea-side plants is the common *Bramble*; for light soils, too, I may mention *Broom* of various kinds, also *Furze*, the dwarf, the common, single, and its double variety. I think I have now answered all "Salmoniceps's" objections, and I hope he will add to my list considerably, as he seems to have experience in regard to sea-coast planting. Perhaps Mr. Munro, at Cleveland, Lyme Regis, would tell us how the *Camellias* do there. I know there used to be some good plants of them on that coast.

JOHN SCOTT.

FIR TIMBER.

VARIETIES of the Scotch Fir are to be found all over the Continent of Europe, and its great use in building has led to the development of a trade in it which was far from being anticipated a century ago. The high rate of duty charged thirty or forty years ago was against the true interests of commerce, and the vexatious hindrance to business inflicted by customs' regulations did much to discourage building. Wood was then bonded, and the duty paid as occasion arose. The result was a very great loss of time, and the speculations as to the lessening or increasing the tax consequent on the approach of every budget were a source of great disturbance and injury to the market. Entirely free from such disadvantages, the trade in wood, especially of Fir, has assumed colossal proportions, and is increasing every year. *Onega* is the best description, being fine-grained, generally free from sap, durable, and easily worked, but its price is so high that it is not at all in general use. *Archangel*, though coarser in grain, is more used, but not to such an extent as formerly, although it has not advanced in price to the same extent as other wood. It is of a soft silky nature, and is also easily worked. The Maymax saw-mills send some very good samples to the market, and those

requiring good quality and long lengths can be accommodated in this description of goods. *St. Petersburg* wood is more largely used than *Onega* or *Archangel*, but the quality is not so good as it used to be twenty years ago, when Gromoff's shipments were in such great demand. The whitewood is much used in this market, and works very well. *Wyburg* is a very useful quality. The wood is close-grained, and, although cheaper, is often very difficult to distinguish from *St. Petersburg*, but, like all Russian goods, it has an often successful competitor in Swedish wood. It is more liable to sap and shakes than other Russian deals, but when free from these defects no wood can be more useful for flooring, and most kinds of indoor work. *Fredricksham* is of similar description, and with the same may be classed *Uleaborg*, *Tornea*, *Abo*, and *Bjorneborg*. *Riga* white is extensively used. The grain is generally coarse, but the wood sound, and well spoken of for its utility. There are other timber ports in the Gulf of Finland, but the differences in quality are not so striking as to call for special notice. Swedish wood has been attracting much attention of late years, and it is sent here from about forty ports. *Gefle* has been known in this country for many years, and it is a very durable and valuable wood. There is a family likeness amongst the products of all the other ports, which send us the same species of timber from all, the only variation in quality being due to the difference in soil, and the generally favourable or unfavourable surroundings of the trees. Messrs. Dickson Brothers & Co. have a great repute as good shippers, and their shipments from *Gothenburg*, *Holmsund*, *Husum*, *Swartwick*, and *Sundswall* command very high prices. The latter deals are very good and easy to work, and are generally very free from knots and sap. The very high rates do not appear to affect the importations; and the question is, whether they are not much too high to last. We get but few Prussian deals into the market; but they are useful for carpenters or rough work, the large knots and coarse grain rendering them unfit for anything else. *Norway* deals run of small scantling; but much is of very good quality, such as *Namsos*, *Laurvig*, *Vefsen*, *Dram*, &c. The latter are principally $2\frac{1}{2}$ by $6\frac{1}{2}$, and lately have turned out very well, and brought good prices; but, when they are bad, no wood can be worse. Sap, knots, wane, and shakes are then in abundance, so that even a firewood manufacturer would not be anxious to buy them. In square or balk timber *Riga*, *Memel*, and *Dantzic* are the staple, but the first is scantily imported. Its great strength and durability make it very valuable for building purposes. Nothing can exceed the best qualities of *Memel* and *Dantzic* for cleanness, straightness of grain, and freedom from knots, but the great price restricts their use to a very great extent. The inferior qualities, especially of *Dantzic*, are, as might be expected, coarse and knotty, the knots in *Dantzic* especially being very large. There is much more demand for Swedish, as it is much cheaper, although it does not run to such a great scantling. It is more like red Pine than is any other timber, and is frequently used as a substitute. It will be seen from the foregoing remarks that we are largely dependent on Fir for building purposes, and that the state of the market, however unfavourable, causes no decrease in the imports. But year by year the expense is increased, as the wood has to be brought further, thus increasing the free-on-board cost, although by no means to the extent that prices have advanced.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Flowering Currants as Standards.—*Ribes sanguineum*, now in full bloom, is grown effectively in this way in Mr. Rumsey's nursery, at Waltham Cross. The stems are $4\frac{1}{2}$ feet high, and the heads from 2 to 3 feet in circumference. Mixed with evergreens in shrubberies, such plants have a fine appearance.

Ornamental Hedging.—We learn, from the *New York Tribune*, that in America the Hemlock Spruce is the evergreen, *par excellence*, for ornamental hedging. Combining, as it does, all the excellencies of other species, it will, in addition, thrive beneath the shade of trees, where most Conifers, except, perhaps, *Yew*, would fail.

Berberis Darwinii.—This is now flowering freely in the Royal Gardens at Kew, where it forms neat little bushes a yard high, and nearly as much through. At this time of the year it is most attractive when covered with its bright glossy leaves and clusters of deep orange-yellow flowers. This I consider to be one of the very best of all the *Berberises*, and in Devonshire I have seen it flowering freely all through the winter.—N. P.

Berberis atropurpurea.—Is this Barberry evergreen or is it deciduous?—J. M. [It is merely a variety of the common Barberry, with dark purple leaves. It bears a profusion of flowers, which are succeeded by berries of a dark colour, and of no great beauty; yet it should be in every collection, on account of its hardiness, retaining, as it does, its foliage for a considerable length of time during winter.—Ed.]

Abies polita.—I have had a young Fir sent me under this name; can you give me any information respecting it?—J. S. [Among Conifers introduced from Japan, this is one of the handsomest. Its leaves, when full grown, are long, curved, and four-sided, broad at the base, gradually narrowing to a stiff point, and of a pale green colour, with which the large, globose, reddish-brown buds form a striking contrast. It is said to be quite hardy in this country.—Ed.]

A HOLIDAY IN THE SOUTH.

By THE EDITOR.

ITALY.

HE who would see nature as well as art in Italy should go there in summer or in autumn. Summer is as great an improvement on winter on the slopes of the Apennines as on those of the Alps. The trees are now bare, or carry dead leaves only; the Grass, or what answers for it, is brown; the mountain slopes, not snowed over, seem arid as the desert; and, in much of the country, the only verdure noticeable is that of the Pines, dimly seen spotting the snow of the high ranges. Southwards, the grey Olive and the deep-green pointed Cypress soften the effect a little; but, as a rule, there is little to be seen to give an idea of the great natural beauty of the country. An acre of mountain pasture over Lake Como or Maggiore, with Gentians, and mountain Primroses, and Cyclamens sparkling in the tender young Grass in June, is worth, to the eye, a hundred miles of Italy in March. It is the same with the fields and gardens—they are as bare as our own in January. The country is in many parts a vast Vine-trellis; but the Vines are still asleep. The Fig and Mulberry plantations are bare as our own orchards. It is true you here and there, going southwards, see the “golden apples” of the Orange in gardens; but the tree looks a little delicate and pale, as if it ought to be sent to Florida, or Sicily, or Madeira for the good of its health. How different must all seem when the hill pastures are Iris-dyed with flowers, or when Grapes, Figs, and Melons abound in the gardens, and when the woods are dressed once more in green! The first impression of the country, then, is not a favourable one, from the absence of a sufficiency of trees, even in the most populous and wealthy districts. The hill-sides are literally sown with villas in many parts; but large, and often attractive, as these are, they add but little beauty to the country from being, for the most part, ungraced by trees. Here and there, the feathery shafts of a grove of Cypresses, and, perhaps, a few other trees, are grouped round a country house; but, for the most part, the houses on the hills, even round Florence, look in winter like band-boxes scattered over a knoll of brown turf. Assuredly here men learned to “build stately” before they did to “garden finely!” Plant round these houses, in imagination, such tree ornaments as grace nearly every country house or villa in England, and we may picture a paradise indeed. The tree which first impresses the traveller in Italy, and mitigates the severity of his journey from the Alps to the south, is the Evergreen Cypress (*Cupressus sempervirens*). It is planted so frequently, and, no doubt, sows itself so often, that the country here and there reminds one of the mountains on the banks of the Hudson River, and other parts of North America, that are freely dotted over with the tapering columns of the Virginian Cedar. But, of all trees with a conical or tapering form, from the Irish Yew to the Lombardy Poplar, this Cypress has the most graceful port, the head often tapering as elegantly and as gradually as the young stem of a Bamboo. The tree thrives freely in the southern and milder districts of England and Ireland, and should be more frequently planted and artistically used.

Naples.

It is sweet to one coming from the harsh north to this sunny city by the sea, to find Acacias in all the glory of their golden hair, free and in the open air with Camellias, Oleanders, the Loquat, the Norfolk Island Pine, and, best of all, with the Palm. Various Palms live out of doors here, but the Prince of all is the Date. I had no idea it was so beautiful, familiar as it is in every Palm-house or winter-garden. The crowding in these houses, and perhaps the houses themselves, prevent the beauty of the plants from being seen. I have been fortunate enough to see numbers of plants which we cherish in our hothouses thriving freely in the open air, and though the difference frequently caused me to form quite a fresh estimate of the plants, no old friend removed from the imprisonment of the conservatory to the freedom of the open air ever seemed so greatly improved thereby. But here I behold a stately shaft (often with little creepers and other plants rooted in the interstices where the old leaves have been removed), 15 to 30 feet high, and from its crest a fountain of superb leaves sweeping out into the sky—a thousand lines of beauty in one stately

bouquet! Let us imagine such a tree laden with its huge drooping chains of golden fruit, of which the desert-dweller makes his food, and we have an object which the highest cultivation in hot-houses can never present to us. Another well-known conservatory tree, the Norfolk Island Pine, and also Cook's Pine, are very beautiful when planted out-of-doors in a favourable climate, the peculiarly graceful habit of each being essentially distinct from anything among the Pines of the northern hemisphere. The cliffs that face the sea here, and the rock-cuttings through many of the suburban gardens, are garnished by an ice-plant (*Mesembryanthemum*), which is quite a treasure in a sunny land. It falls down in curtains from 6 to 15 feet long, forming wreaths and veils as graceful as ever woven by Ivy or Vine leaves, verdant at all seasons, and in early summer crowded with bright rosy stars. If the *Mesembryanthemums* grown in houses were allowed to hang down in like manner, they would prove valuable ornaments for gardens generally. The rocks are also covered in many parts with Prickly Pear and the American Aloe, with here and there sweet-smelling tufts of the common Stock; but, chief of all the beauties of this kind, are large isolated plants of the variegated American Aloe, forming colossal rosettes of green and gold. Where the Agaves crowd each other, as in hedges or wide ledges, they lose nearly all that marked character which they show when grown large and seen in small numbers.

The Royal Gardens at Caserta.

ABOUT an hour by rail from Naples—twenty miles of vineyards, by the way, are passed—there is a vast palace and a vast garden. It may be called the Versailles of Naples, though it differs in detail considerably. But the spirit is the same, a huge garden, not only without life, variety, or nature in it, but, with full precautions taken to shut these out. You enter through a huge royal palace, which seems admirably suited for accommodating several regiments of Life-Guards, when the scene depicted in the illustration meets the eye—the huge cascade facing a distant hill covered with Evergreen Oak. Good as the cut is, it can give little idea of the enormous length of these garden water-works, long and well-constructed stone reaches of deep clear water, broken here and there by falls, which are embellished by a rich display of sculpture and statuary. But, before reaching the water-works, we have to traverse a very large space, by habit called a garden, but which is simply a huge expanse of turf, on which stand clumps and squares, and avenues of trees. We have to approach these closely to see what they are composed of, for all are either clipped or mown, or in some way mutilated, till they lose all individual character, and merely form irregular walls of vegetation. Well, perhaps, we ought to be grateful for so much, but, at the very least, we may ask that such work may not be called gardening! And, still less, does that term belong to the gigantic exhibition of the sculptor's and the builder's art, which succeeds this dreary expanse as one mounts the hill. Under one of the falls, there is a vast covered way, with well-constructed rocky walks and walls, and here the Maiden-hair Fern grows everywhere as freely as Meadow-Grass; it even ventures out from the moist and shaded grottoes, and creeps into the eyes and ears of the spouting sea-monsters outside in the sun—the only trace of life or Nature near. The distressing effect of all this gradually passes away, for one of relief, as the base of the great irregular (but also artificial) cascade is reached, till the eye dwells happily on the hills around, densely garlanded with Evergreen Oak. All this kind of “art” comes from allowing the space intended for a garden to be converted into an open-air gallery for the exhibition of architecture, sculpture, &c., mostly of a mediocre, and often of a feeble or ridiculous, character. The clipped trees and shorn woods mainly serve to prevent the scene from having too startling a resemblance to a sculptor's show-yard. Such scenes may, perhaps, have some obscure justification in the history of art, wholly, it is to be hoped, in showing us what to avoid in future. Let us not, however, delude ourselves into the belief, that, in creating such scenes, on either a large or small scale, we are making a garden. There is at Caserta, however, an example of one phase of real gardening, which, if the visitor is not

VIEW IN THE ROYAL GARDENS OF CASERTA, NEAR NAPLES.

exhausted by the display just alluded to, will repay the visit. It is what is called the English garden, a large piece of diversified pleasure ground, with many trees allowed to assume their natural development. Towards the end of the last century this garden was planted, and with a very happy result. The great geometrical district, so to say, gives one an idea that the region is not a fertile one; this is at once dispelled on entering the English garden. The Cedars, Cypresses, and deciduous trees have attained great size and beauty, and grow in stately groups, with open spaces between, so that their forms may be seen. Here is the first Camellia ever introduced into Italy, where the plant is now so abundantly grown, and whence we get most of our new varieties. It is a specimen of the single red, now in full bloom, and about 20 feet high and 15 feet through. The Camphor tree is seen in fine health here, in specimens nearly 50 feet. By the way, as the Gum-tree is now being planted as a health-giver, why do not some of the countrymen of Raspail—the great apostle of the virtues of camphor—try this tree in southern France? The garden is enriched by some noble Cork trees which may give many visitors a fair idea of what a noble tree this Oak is when fully developed. The trees are huge in stem, picturesque in their branching, and about 80 feet high. Some of the scarcer Pines attain much perfection here, as, for example, the Mexican (*P. Montezuma*) which is 60 feet high. But, to English eyes, the most striking plant of the Pine tribe, is *Podocarpus elongatus*, one of a family which has found a place in our gardens of late years; it is about 25 feet high, and, in form, like a very slender Irish Yew, somewhat too open and thin, perhaps, but this may be accounted for by the position in which it grew being a shaded one. It is likely some of this family, from their form, will prove very valuable in our gardens. Here are some remarkably fine specimens of the Stone Pine—the table-headed tree, which, after the Cypress, gives such a marked character to the landscape in many parts of Italy. In the field, where the tree is cultivated both for its fruit and wood, it is seldom very large, in consequence of the lower branches being continually cut for firewood. What is this seen through openings between the stems of dark Pines and Cypresses that fringe a glade—a large mound of light golden colour, startling in contrast to the vegetation around? It is a large tree, the silvery-leaved *Acacia* (*A. dealbata*), more than 40 feet through, about the same in height, and so full of blossom, that all its delicate silvery and exquisitely graceful leaves are buried in the foam of colour that has burst out all over the tree—a tree of gold; but of gold wrought into aerial fineness of silken floss by the Weaver of the humming-bird's wing, and of the purple curtains of the sky. It seems odd to feel very chilly under a great-coat in a garden where such a tree flowers in a cold March; but no doubt the great summer heat develops and ripens the tree so as to enable it to endure the subsequent cold of winter and spring.

A Neapolitan Villa Garden.

The hills round Naples have quite a deciduous look in winter, and it is only in some of the villa gardens near the sea that one sees what the garden may be made here. Imagine a house on the rocks, directly over the margin of a little bay, with a zigzag drive down to it, between walls of rock on each side. These walls are curtained with *Mesembryanthemum*, the plant falling in wreaths and sheets to a length of 18 feet; while, on the top of the rock, the American Aloe masses itself in groups. The precipitous nature of the site has caused the greatest difficulty in the making of the walks, &c., while the ground has to be terraced like steps of stairs, so as to keep soil and plants in a level position, and also to give an opportunity of watering them. High behind the house the cliffs rise, sheltering the garden from the north-east, and enclosing, as with a high wall, a much broken and diversified nook of rocky ground, where the banks are very steep, the *Mesembryanthemum* is pricked over their surface, and soon forms a fresh sheet of green over the whole, and one unfading at all seasons. We have no plant that will cover dry banks so well, and it is a pity it is not hardy enough for colder countries. Here and there a superb plant of the variegated American Aloe is seen—a colossal rosette of gold and green, from 8 to 10 feet in diameter. It is a pity such a strik-

ing and easily-grown plant is not more frequently seen with us in a large state. Not less striking, when fully developed on a sunny ledge, is the Prickly Pear, which holds up its shield-like leaves to a height of 10 or 12 feet. Here and there a bright coral-red head of flowers enlivens the scene; it is one of the common small *Agaves*, which we never think of growing for the beauty of their flowers; though here, throughout the winter and spring months, they are as valuable as the *Tritomas* in England in the autumn. The ground is carpeted with two Wood Sorrels, a yellow and a crimson (*O. cernua* and *O. spectabilis*); the *Tazetta* Daffodil is wild in the Grass, and so is the Cyclamen on the bank. There has been frost here, but the dry soil and air saved the plants, and our graceful friend, the Ivy-leaved Geranium, falls—Ivy-like—6 feet over the edges of the stone walls and rocks. Against a warm wall the giant Peruvian Cactus (*Cereus peruvianus*) attains a height of 30 feet, and the well-known *Bonaparteia* (or *Littæa*) of our hot-houses bears a flower-spike 14 feet high. This stout and dark evergreen tree, with handsome leaves, is the Locust tree, and this graceful Reed in the fountain-basin the Papyrus plant of the Egyptians, on the pith of which books were written in the old times. On the small lawn there is a healthy plantation of Camellias of many kinds in flower; near it a grove of Oleanders and a plantation of the Loquat, while, of course, the many bright fruits on the Orange trees tell boldly in the garden landscape. Here, too, is the Date, with its large tassels of orange fruit-stems, and the Fan Palm and the Cycas all lend their aid. Here, too, are the Evergreen Cypresses and various trees of our own gardens, and superb specimens of the Stone Pine, with its great spreading or tabular head. With all this variety from many climes it may be thought that the scene is of a higher beauty than an equally well-arranged one in our own gardens. This is not so. These Plumbago and Passion-flowers that curtain the rocks, do not do so more gracefully than climbing Roses or Virginian Creeper would, and the garden-products of a much cooler country tastefully combined, yield as good, or a better result. While the villa of the royal palace here has its garden more or less attractive, there seems a total absence of the smaller kind of garden which abound in England. Here, the lower-middle and working classes live in huge barracks that stretch for miles around the bay, and are as dreary in aspect as so many factory walls. Two gardens, that of the Villa Matilda and La Floridiana, are of the above description and are among the most beautiful near Naples. The garden of the Prince Colonna-Stigliano is in the city itself, closed in by high walls, and very beautifully arranged in the recent French style, that is to say, with open spaces of Grass and no formal set of flower-beds anywhere. Here are admirable and rare specimens of such Palms as the *Latania*, are isolated on the turf and relieved by a Tree-Fern (*Alsophila australis*), a tall plant with a few young ones of the same kind grouped round its base, grand trees of *Eucalyptus*, and many choice trees and shrubs. Here, a small structure built in the Orangery fashion is laid out as a very effective little winter garden. Healthy and effective plants only are used instead of the miscellaneous rubbish which usually occurs in such structures on the Continent. By throwing the plants into tastefully arranged groups and masses, sprinkling a few spring-flowers like Hyacinths, &c., towards the edge of each group, a very graceful effect is obtained, quite as good as that of a conservatory. There is, also, a long greenhouse arranged in the natural style, with winding walks and many fine-foliage plants, and the effect of this is also very charming. In fact, the whole garden is most tastefully disposed, and very suggestive of the best way to treat a city garden. Here it may be stated that the Aloe which is such a conspicuous flower in Naples gardens, is *A. vulgaris*, and the Ice plant, which covers the dry slopes and hangs from the high rocks, is *Mesembryanthemum rubrocinctum*.

The Royal Botanic Gardens at Naples.

An old-fashioned botanic garden, and certainly uglier than the Garden of Plants, at Paris, to which we have long given the palm in that way. A great central road-like walk, a few squares, the surrounding houses staring into the garden—that is all, except the plants. The whole place is about as large and ornamental enough to afford a site for a burial ground for

some small village or hamlet. This is, of course, speaking in relation to the importance of the city, and to the good that a national garden, worthy of the name, would do for a country like this. Imagine what might be done in a suitable and sufficiently large site in a climate where the Date Palm and the Weeping Willow, the Orange and the Plum, the Oleander and the Cherry Laurel, the Acacia and the Hawthorn, the Camellia and the Rose, all flourish together in the same garden! But it is the old story: a generous clime does not of itself make a good garden or gardener. Very often under a northern sky, and with much fewer kinds of plants, prettier garden pictures are produced than in the finest climates. But, suppose we bring the northern gardener to the southern climate, and give him *carte blanche*. This is what might be done with great advantage in many southern gardens, where one of the most instructive arrangements in the botanic gardens is a collection of all the Orange tribe—from the delicate little Mandarin to the huge Shaddock. Though the trees fruit freely here, they do not possess that glossy health which one likes to see in an ever-

green display; and a climate a little warmer would seem to be desirable—if not for the trees, at least for those who plant them. Sitting in the sun in a Neapolitan Orange-grove in winter is very pleasant, provided one is enveloped in several great-coats or blankets. The cold icy air that searches one through on ascending any eminence is quite a lesson to the Britisher who innocently supposes himself to have escaped, for a time, disagreeable weather. A noble looking tree, the Mexican Taxodium (*T. mucronatum*), has attained a large size here. Like the well-known deciduous Cypress, which attains such great size at Syon, and in other gardens, it is graceful in foliage and stately in port; but it is moreover, peculiarly graceful from the shoots being bent down by graceful tassels, composed of the small whip-like racemes of male flowers. This must be a most valuable tree for many countries. In March, at Naples, it retains its leaves; but they are quite brown. The single Kerria

(*K. japonica*), that is, the original form of the double Kerria seen on many cottage walls in England, is here in fine condition—a graceful shrub, with slender shoots, bearing many deep rich yellow flowers, like small single yellow Roses. It has merit enough to deserve a place in every garden. There is a fine specimen here of the horizontal, or spreading, form of the Evergreen Cypress, by no means so valuable as the common form, though a valuable tree in its way. The finest tree in the garden is *C. glauca* var. *pendula*—a weeping tree, and a most picturesque one. It is finer than the Chinese Funeral Cypress, which does well hereabouts. The Plane tree thrives grandly here, as it seems to do in every cold or temperate country. As another contribution to the already wearisome controversy as to the names of the Planes, it may be stated that a noble avenue of trees here is labelled "*Platanus acerifolia*." It is the same as the London Plane; but from the freer growth and the clearer air, the whole of the branches as well as the branchlets are nearly white, so that the effect when the trees are naked, as now, is very striking. A

curious pretty object occurs here, an accidental effect, in a house built like an Orangery, with glass and pillars in front, with a roof and back like an ordinary chamber. A plant of the creeping Fig is placed inside against one of the pillars. It runs up 20 feet or so, densely covering the pillar, then spreads over the white ceiling and down the back wall, of course, without any training whatever. The part of the roof nearest the front is covered most densely, but beyond this, where the long thread-like shoots run over the roof and cross each other here, affixing leaves to the roof as they go along, the effect is marvellously pretty, as if some cunning artist had inlaid the roof with exquisite filagree work of enamel. One of the best of the yellow Wood-Sorrels (*Oxalis cernua*), seems naturalised here, and is very pretty—a mass of soft-golden flowers on a turf of trifoliate leaves. Two weeping trees are seen here that seem valuable for all cool temperate climes, the so-called Pepper-tree (*Schinus Molle*) and the Australian Beef-Wood (*Casuarina*), all the cord-like branchlets of which are gracefully pendulous. Some of the *Casuarinas* deserve, from their peculiar grace, a place in our conservatories. The *Dasyliirions*, as yet

somewhat uncommon in our gardens, are here planted out, and spread into superb rosettes of foliage. They seem as hardy as the Aloe-leaved Yucca (*Y. Aloifolia*), which here breaks into many stems, assumes a tree-like form and reaches 15 feet high or so; it is never so graceful, however, as when confined to a single stem. The Gum-trees, so much talked of, thrive here (but not so well as in California, where they grow beautifully), and the Loquat and the Oleander are at home. If the "fever-destroying tree" is wanted anywhere, it is in many of the malaria-haunted valleys of Italy. Here, too, occur good specimens of that singularly graceful Palm (*Phoenix leonensis*). It is valuable in consequence of being of a much dwarfer and more graceful character than the common Date, and better suited for winter-gardens and conservatories. The true Date, however, is the more stately in port.

Pompeii.

A well-cultivated plain; the peasants busy trimming

the Vines; the air delicately scented with the odour of Bean-fields, in full bloom in March, a few big orchards and Stone Pines breaking the somewhat monotonous level of the field-culture; southwards, and not distant, a broken range (the Mountains of St. Angelo); northwards, and near at hand, one stately mountain, with a cloud of steam at its apex, differing, apparently, in no respect from an ordinary white cloud! A little way off there is a long ridge of what looks like broken whitish stone, to the further end of which a stream of boys, bearing baskets on their shoulders, are continually adding. We approach the spot, and are standing about 30 feet over the floors of the, as yet, unexcavated houses of Pompeii. Looking seawards, we see what appears to be the remains of the basement story of a city, the walls erect, the pavement of the long lonely streets smooth and bright. We descend, passing the boys hurrying up the slope, carrying pumice-rubble from a house in course of excavation. On the wall of the upper storey there is a fresco painting, exposed to view a day or two since, after being buried for eighteen hundred years, yet now fresh and distinct as

Phoenix leonensis.

foliage on new wall-paper. At the base of the wall of the ground-floor, where only a small portion is as yet uncovered, there is a fresco painting of a plant like a wavy-leaved Aloe, and beside it one resembling the Chinese Iris. As we pass through many of the houses excavated in the present century, whose best treasures are now in the museum at Naples, it is interesting to observe that paintings of plants occur all round the base of the walls, not only of what were the sitting-rooms, but, also, in some cases, of the narrow passages and entrances. Invariably the upper portion of the wall is embellished with pictures of human life, or of human interest; while below, on the space within 18 inches of the ground, portraits of plants may be distinctly traced, painted as if growing from the ground. Conventional drawings of plants also occur, but are much rarer than these. Since their exposure to the weather they appear to be fading too rapidly, but, doubtless, numerous paintings and engravings will perpetuate for all time, these, as well as all other details of discoveries so precious to humanity. Among the numbers of interesting objects found buried in Pompeii, none are of greater interest than the various kinds of seeds and fruits used as food. All have a black or charred look, and some have been pressed into a firm mass, but all are as perfectly recognisable, by those who know the same kinds in a living state, as the perfectly-preserved Walnuts. Among the seeds, are those of the Stone Pine, then, as now, used as food. It is now everywhere grown in the fields and gardens here both for the sake of its fruit and its wood. So it, doubtless, was on the same ground two thousand years ago. There is pretty good evidence that the pointed Cypress also occupied, in those old days, the same place in Italian gardens as it does at present. In one of the landscape frescoes, on the walls here, there are good representations of two specimens of this tree, which, no doubt, was employed here in the "street of tombs," that most interesting of all burial-places. This, being wholly devoid of the horrors of the modern cemetery, containing, as it did, only the cinerary urns of the dead and their varied memorials, formed what was certainly the most beautiful street of the city. To this street of tombs the Goddess of the Woods returned once more with the sun, and planted a few Cypress seeds, which soon sent up their graceful forms, now, in their perennial verdure, mourning for the great of old beside what remains of their exquisitely-sculptured monuments. Even here, in this closely-built and strongly-walled city, there seems, so far as the excavations have yet been carried out, no space for out-of-door gardens; but many of the houses had a spacious court, open to the sky in the middle, with a colonnade all round, and a fountain and little garden in the centre. In one case (in the house of Meleager and Atalanta), the remains of many of the shrubs with which the garden was planted were found. In various instances, provision seems to have been made for the planting of flowers in the marble-work of the fountains, marble water-basins, and in the hollows of the wall which fills the inter-columniations in the elegant peristyle of the house of Narcissus. Most interesting of all, however, are the admirable arrangements for a supply of water in the gardens. Here, in the garden, or *viridarium*, of Marcus Lucretius, are many excellent strongly-constructed leaden water-pipes, now in perfect preservation! In addition to the large pipe or main supply, and minor ones conveying water to the fountain, &c., the ends of pipes project from many of the pillars of the colonnade which surrounded the garden. Marcus Lucretius had certainly conquered the difficulty of supplying his garden with water, and in a manner that many a nineteenth century gardener would envy. Those accustomed to complacently admire the "latest modern improvements" in the way of water-supply, may well open their eyes here, as these strong snake-like conduits show here and there beneath their feet in the street, and their bronze taps stand up as perfect as if placed in position last summer. Thus it is clear that these old "pagans" who conquered and civilised, and ruled and built, and fought like gods, had also gentle fancies for refinements, sometimes supposed to be the growth of a later time. But we must leave this silent city for the busy fields and gardens without touching on many of its unequalled sources of general interest, which show clearly enough that, so far as the social life of man is concerned, the two thousand years that have passed since Pompeii flourished, have effected little real

improvement. Let us hope the next two thousand will prove a more fertile era for human progress. This towering Vesuvius almost deserves our gratitude for preserving so much from time and the barbarians. It is no friend to vegetation, however, as those trees could tell which are overtaken by a stream of lava. An English friend, who has lived here for years, tells me that he watched the progress of the last great eruption with much interest. As the high glowing stream of red-hot molten minerals slowly approached the trees, the branches of some kinds took fire and blazed away a considerable time before the bole was touched by the slowly-moving mass; the bole itself only blazed upon being broken and overthrown by the advancing wall of fire. As the lava takes three years to cool, it need hardly be remarked that the surface is still barren, yet the softer kinds of volcanic ejection, such as those which covered Pompeii, for example, soon crumble into deep and excellent earth. The low grounds round Vesuvius are fertile and well cultivated, as is nearly all the level country near Naples. We sometimes read of ground in the colonies being worn out and abandoned, and this in places only occupied by man for a few generations. Yet, here the same kind of culture has been carried on for, probably, not less than three thousand years, and the land seems capable of any amount of further cultivation or improvement. So much for "wearing out."

THE FRUIT GARDEN.

GOOSEBERRY TREES TRAINED AS PYRAMIDS.

By P. GRIEVE, Culford Gardens, Bury St. Edmunds.!

THE Gooseberry in both its rough and its smooth form is indigenous to Britain, where it has been cultivated from time immemorial, and regarded as the most useful and wholesome of bush fruit. So much is this the case, that it may even be doubted, if it has yet received the amount of attention, to which its merits, as a wholesome and really delicious fruit entitle it. It is true that considerable interest is taken in its cultivation in some parts of the country, more particularly, perhaps, in the northern counties of England. Still this attention would appear to have been directed more towards the increase of the weight and dimensions of certain favourite sorts, than in attempting to obtain varieties of superior quality or flavour, or in the adoption of improved methods of culture. It is quite possible that this useful and esteemed fruit may attain to a greater degree of excellence in the more moist and cool atmosphere of the north or north-western portions of our island, than it does in the keen breezes of the eastern counties, or even in the more favoured climate of the sunny south. It will, nevertheless, accommodate itself to, and succeed in almost all varieties of soils and situations, and its culture is consequently, universally adopted. The celebrated Lancashire show varieties of this fruit, are admitted to be more remarkable for their great size and weight than for their fine flavour; but, at the same time, there exists an almost infinite variety of sorts, many of which are of such excellent quality, that to improve upon them would be exceedingly difficult. As a really wholesome fruit, the Gooseberry must be admitted to stand pre-eminent; for, while it is frequently considered necessary to partake of other fruits, with something like caution, the Gooseberry, on the contrary, may generally be indulged in, to any reasonable extent, without apprehension of injury. And those who have never eaten of this delicious fruit, direct from the bushes, in the comparatively cool atmosphere of an early August morning, there yet remains a treat in store, the enjoyment of which might form an incentive to the salubrious habit of early rising. The Gooseberry in all its varieties is generally cultivated in the form of dwarf, flat, or squat bushes, and its motto may be said to be *Nemo me impune lacessit*, and these circumstances render the operation of gathering the fruit, sometimes less agreeable than could be desired. But the method of culture which I am about to describe, will, if adopted, to a very considerable extent ameliorate this evil. The system has been practised here, during many years; and this, or something similar to it, may also have been followed in other garden establishments, so that it is no means recommended as a novelty. But as it still co

tinues to attract the attention, as well as to meet the approval of the generality of visitors, I will endeavour, in as few words as possible, to describe it, and may, in the first place, say that in forming a plantation of pyramidal Gooseberry trees, such as I am about to recommend, it is necessary, in the first instance, that the piece of ground selected for it should receive every necessary attention, such as draining (if required), deep trenching, liberal manuring, &c.; and, if the soil is of a light or sandy nature, a good dressing of clay would be found to have a very beneficial effect. For, although, as

has already been said, the Gooseberry will succeed well in almost all sorts of soils, still it must be borne in mind that this crop differs considerably from the ordinary annual and biennial crops of the garden. Inasmuch as these trees or bushes will, in all probability, occupy their position for many years, and although fertilising materials can, from time to time, be supplied to the soil, as may seem necessary, it is, nevertheless, advisable to have the soil in good condition when the plantation is formed. This preparation of the soil should be attended to at as early a period of the autumn as possible, in order that it may have time to settle, before the trees are planted, which should be done not later than the middle of December; and, if earlier, so much the better. Supposing the site for this plantation to be in readiness, let lines be drawn upon it, north and south, at a distance of $6\frac{1}{2}$

feet from each other, and intersect these lines by others, running east and west, and at the same distance apart, viz., $6\frac{1}{2}$ feet. Proceed to get ready the necessary number of strong straight Larch poles or stakes, which should be some 12 or 14 inches in circumference at the larger end, and about $8\frac{1}{2}$ feet in length; they should be sharpened at the larger ends, which are intended to be driven into the soil. But, before this is done, about 2 feet of the end intended to be so used should be well charred by being held over a fire; or the ends of the stakes may, to that depth,

be dipped in boiling pitch. The object, in either case, being to render the portion of the stakes driven into the soil, as far as possible, impervious to moisture, and to be thereby rendered more durable; and this charring or coating with hot pitch should extend to at least 6 inches above the surface of the soil, where decay is most likely to take place. The sharpened ends of the stakes should now be driven into the soil, at the points where the lines intersect each other, taking care to keep them in an upright position, and rendered steady by having the soil firmly rammed around them. Each

pole or stake should stand exactly 7 feet above the level of the soil. This height is necessary in order to give sufficient head-room, as will be forthwith explained. It is not unlikely that the difficulty of obtaining Larch or other stakes for this purpose may, in some instances, be considered an insuperable objection to this pyramidal system of training the Gooseberry. But, in almost all woodland districts, little, if any, difficulty need be experienced in procuring the thinnings of Larch plantations; and, in all localities they may, no doubt, be obtained at a moderate cost, say from 3d. to 6d. each, according to size, &c. It should be remembered that, with proper care in charring or coating the lower ends with pitch, or some similar material, they will last, without further trouble or expense, for at least ten or fifteen years. When they have been all properly fixed in the soil, they will be found

Trees destroyed by lava (see p. 312).

to stand at a distance of 6 feet 6 inches from each other, and should also be 7 feet in height. A moderately strong galvanised wire should now be made to extend from the top of one stake to that of another, and should be secured to the central part of the same by a strong iron staple, which should be made to secure both wires—that is, that which extends from north to south, as well as that which stretches from east to west. When this has been done, the top of the stake should be thickly coated with pitch, which, by excluding air and moisture, will for a long period prevent decay, and also prevent the staples which

hold the wires in their position from becoming loose. But the fixing of these wires may, if desired, be deferred for at least two seasons after the plantation has been formed, as that time, at least, will elapse before the plants can reach to the top of the stakes. It is, however, advisable to fix the wires as soon as the stakes are inserted in the soil, as they tend to keep them in their proper form, and prevent the possibility of their being loosened by high winds, or other causes. Should wire be considered as too expensive to be used for this purpose, strong tarred cord or line may be substituted for it, which could be renewed when worn out. But it is obvious that wire is the most satisfactory material to use for the purpose, although more expensive in the first instance. The plants used to form this plantation should have been struck from cuttings in the usual way, and should each have four leading shoots or branches. They should be planted as carefully as possible on either the south or the north side of the stakes, and within about 2 inches of the same; and the four leading shoots should be tied or nailed to it, keeping them as nearly as possible at equal distances from each other. Or two plants may be placed to each stake, one on the south and the other on the north side, and, in this case, only two shoots will be required to be taken from each plant. By adopting this plan, the stakes will be clothed somewhat sooner. When the plants begin to grow freely, the lateral branches on the lower part of the tree or bush may be allowed to extend themselves, in order to form the foundation of the pyramidal form which they are ultimately intended to assume; while the progress of the four leading shoots must be encouraged by every possible means, and, when they reach the top of the stake, each shoot must be trained along its proper wire until it meets and unites with that of the next tree, and so on. As soon as the stakes and wires have been properly fixed, and the Gooseberry trees are planted, &c., the soil (upon which considerable treading has been necessary) should again be lightly dug or forked over, and a line or row of Strawberry plants may be turned out between each line of staked Gooseberry trees, and intersecting each other in like manner. These may be allowed to remain during the first two seasons; after which, the entire space will be required by the Gooseberries, and the Strawberry plants may be dug into the soil. Annually, after this, as soon as the Gooseberry trees have been pruned, the surface of the soil, to the depth of 2 or 3 inches under the branches and around the stems, should be drawn into the centre of the space between the lines of plants, while that portion of the soil from which the surface has been removed should at once be thickly dusted with gas or quick lime, and some 18 inches of the centre of the space between the lines should be deeply dug, and fresh soil, in proportion to that taken off, must cover the lime under the branches and around the stakes and stems of the plants. By annually pursuing this system, caterpillars will not be likely to be very troublesome, as the larvæ, which are generally hid slightly under the surface of the soil and near to the stems of the trees, are by this practice deeply buried in the centre of the space between the lines of plants, where they probably perish. But, should the caterpillar at any time make its appearance upon the plants, recourse should at once be had to black Hellebore powder, the best and most effectual remedy. In addition to the usual annual pruning which these pyramidal trees should always receive during the winter or early in spring, it is also advisable to go amongst them about the end of June or early in July, and, with a knife or pair of garden-shears, shorten the stronger-growing lateral shoots, with a view to throw additional vigour into the weaker ones, and also to afford greater facility for gathering the fruit by increasing the space between the lines of plants. One of the great and much-appreciated advantages of this system of culture is the facility which it affords to ladies and others to walk among the trees, and to select their favourite sorts, &c., and to be able to gather them without being compelled to stoop, or to raise the branches before the fruit can be gathered. It may be almost unnecessary to say that the Red and the White Currants, with their various varieties, may be equally successfully grown as the Gooseberry when treated in this manner. A square plantation of pyramidal Gooseberry and Currant trees, consisting of some 12 lines or rows, with

twelve plants in each, or 144 plants in all, will, when fairly established, and during favourable seasons, afford a supply of fruit which will be found sufficient for an ordinary establishment. But the plantation can, of course, be of any desired extent, as well as of any form or outline. It will be found to present a striking, and even an ornamental, feature in any garden, and on that account it should always be kept scrupulously clean and free from weeds, &c. Appended to this is a short list of sorts which have been proved to succeed well when treated in the manner described; as, indeed, all known varieties will do. But, at the same time, there are some sorts which, on account of their habit of growth, &c., are better adapted to the purpose than others:—

Red Varieties.—I may commence the list with the Red Champagne, as a variety of medium size, but unequalled in quality and richness of flavour. Crown Bob: A fine, large, and excellent variety. Glorious: Also a large and first-rate sort. Glory of Oldport: An excellent variety. Highlander: A fine rich-coloured and handsome variety. Independent: A fine large late sort, and an excellent bearer. Ironmonger: Fruit, small, but of excellent flavour, and considered good for the purpose of preserving. Jackson's Red: Also a good sort, for the purpose of preserving. Lancashire Hero: A large and excellent variety. Rifleman: Smooth fruit, of medium size, excellent flavour, and an abundant bearer. Rough Red: Fruit, small, but an abundant bearer, and considered as the best sort for preserving. Warrington: This is probably the best and most useful variety of all, hangs long upon the trees, is of first-rate quality, and suitable for preserving, &c.

Green-fruited Varieties.—The best are Greengage: Medium size, with remarkably fine flavour. Greenwood: Fruit large and very good. Green Walnut: A fine variety. Guido: Also a very fine sort. Large late Green: This is a very fine, large, and late sort, of excellent flavour. Wonderful: Also a fine variety.

Yellow-fruited Varieties.—Conquering Hero: A fine, large, handsome variety. Early Sulphur: Very early, with fine flavour, and an abundant bearer. Golden Drop: A fine-flavoured excellent variety. Goldfinder: A first-rate sort. Ploughboy: Fruit small, but good. Waterloo: Small, but very handsome.

White-fruited Varieties.—British Queen: An excellent variety. Large Early White: Fruit, large, early, and of excellent quality. Washington: Of good flavour, and a very fine variety. William the Fourth: A large and fine-flavoured variety. White Eagle: Also a fine large sort. Whitesmith: A very early and large variety, of excellent quality.

While, of suitable varieties of the Currant, there may be mentioned the Cerise, Knight's Long Bunch, La Versaillaise, Large Red Grape, Raby Castle, Transparent, White Grape, and White Dutch.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Golden Champion Grape.—Can any of your readers say whether, in their experience, this Vine is a shy bearer? I have it grafted on Raisin de Calabre, a strong cane; it had a moderate crop in 1872, about five bunches last year, and this season every spur is blind, although, in the same house, all other Vines are showing abundance of fruit. Will any of your readers explain the cause of failure in my instance?—N.

Gooseberries on Walls.—We rarely see Gooseberries growing on walls, but in some cases this may be done with advantage, especially where the wall space is low. Trees thus trained bear abundant crops of fine richly-flavoured fruit, which is much more easily gathered than when grown in the ordinary way. The finest dessert sorts only should be planted. At Woollaton Gardens, near Nottingham, there are some fine old specimens grown in this way, and we never tasted fruit more richly-flavoured than that so grown.—Q.

Sir Philip Crampton's Pear Tree.—This Pear tree, of which we have given an illustration (see p. 417, vol. iv.), presents, it is said, this spring a noteworthy contrast to its appearance last and preceding seasons at this period of the year. Hitherto it was wont to be a marvel of floral beauty, literally one sheet of snowy blossom. At present, the few trusses of bloom with which its surface is irregularly and sparsely dotted, scarcely count two dozen. This, doubtless, arises from its having been over-cropped last year. If fruit-growers generally only allowed their trees—even in the most prolific fruit season—to bear moderately, our fruit crops would be regular, instead of being, as they are, somewhat uncertain.

Origin of the Duchesse d'Angouleme Pear.—A French nobleman observing his tenant about to destroy a fine thrifty Pear tree, inquired the cause. He was told that it was a chance seedling, and had borne no fruit in twenty-five years. He had already cut its roots preparatory to the first stroke but was ordered to let it remain. He did so, and in the following year it was loaded with superb fruit of a new variety, which at once became celebrated. The root-pruning the gardener had given it worked like a charm. Not many years afterwards the Duchesse d'Angouleme was passing through Lyons, and its inhabitants sent to her their hospitalities. Nine fair maidens presented the Duchesse with golden salvers, on which lay heaped this precious fruit, and begged her to bestow on it her name; and the Pear now recognised as one of the best of fruits, was thenceforward known as the Duchesse d'Angouleme.—Cultivator.

GARDEN DESTROYERS.

GARDEN PESTS.

Weevils.

THESE are principally leaf-eating insects, and are sometimes very troublesome both in the grub state as well as when fully matured. They are, like many other unwanted company with which we have to contend, much more numerous in some localities than in others. In one place I found that every year the common brown weevil attacked the Vines just about the time the berries were set. They not only perforated the leaves in all directions, but also attacked the young berries, usually disfiguring the shoulders of a considerable number of the bunches. The mature insect is a night-feeder, and it may then be caught by placing a cloth under the plant it is feeding upon and giving the plant a smart shaking, by which means they will fall off on to the cloth spread out to catch them, when they may be caught and destroyed. Something white, such as a large tablecloth or sheet, should be used, as, from its colour, it enables the weevil to be seen the best.

Earwigs.

Although there are several flowers that earwigs will eat, there is nothing they do so much harm to as the Dahlia, as any grower of this favourite florists' flower can testify. Where they exist in considerable numbers, it is almost an impossibility to get a stand of perfect flowers for the exhibition stage, through their depredations in eating the points of the petals in the young unexpanded flowers. With these, as with most other garden pests, there is no alternative except diligent and timely perseverance in their destruction. The grower that neglects to employ any means for the destruction of this insect until the short time that elapses betwixt his flowers being in bud and their full expansion, will, in all probability, find it a difficult matter to make up the number of perfect flowers he requires for his exhibition stands. For weeks before the plants get so far advanced as this, means to keep them under should be taken. They feed in the night, and any substance in which they can conceal themselves in the day may be employed. The usual practice of placing a small inverted flower-pot with a bit of Moss in the bottom, on the top of the stake to which the plant is tied, is not a bad means catching them, provided they are regularly examined. Another trap commonly used is, small bundles of Bean stalks tied up, cut 6 or 8 inches long, placed in each plant, and looked over daily by shaking the end of the bundle on a board or other substance, by which they can be destroyed. The most simple and effective traps I ever tried were pieces of newspaper, crumpled roughly up in the hand, and stuck anywhere in the plants, unfolding them two or three times a week, when numbers of the insects will be found concealed in them. If there happens to have been bred a nest of young robins near the Dahlia ground, the numbers of earwigs they will eat, when they have taken flight and got old enough to find their own food will astonish anyone taking the trouble to watch their movements. The use of thin muslin bags, in which the buds are placed before they expand, drawn up close round the stalk of the flower so as to prevent the insects getting to them, is also a method followed by some growers. A piece of cotton-wool, twisted round the flower-stem just behind the bud, will prevent them getting to the flowers. By resorting to some or all of these methods, their numbers can be so far kept under as to prevent the disappointment of finding all the best buds rendered useless.

Beetles.

The depredations of beetles do not extend over so wide a field in gardening as some of the pests already treated of. They are the most destructive to Orchids. If allowed to get to any considerable head amongst these plants, the damage done in absolute value becomes a serious matter. They attack the lower-spikes whilst young and tender, and the young growths; still worse, so far as weakening the plants, is the destruction of the roots. When we consider the value of many of the rarest of these plants, the necessity of unremitting attention in the destruction of these pests will be apparent. Nature's instinctive law of self-preservation is more fully exemplified in the species that infest the Orchid-house than in anything else that stands

correspondingly low in the scale of animated nature with which I am acquainted. The moment they are disturbed, the astonishingly rapid powers of motion possessed by these beetles is brought into play. Their movements, especially in the night, when a light is brought to bear upon them, are almost equal to those of a bird. They secrete themselves amongst the drainage of the pots, in the material in which the plants are growing, when it is dry whilst the plants are at rest, in cracks in the walls where the mortar has become displaced, near the pipes, or in any out-of-the-way place. They are very destructive to soft-wooded cuttings and seedlings in the propagating-house. They increase fast, and when once they gain access to a plant-house, are very difficult to completely destroy. The thick fleshy roots of *Vandas*, *Aërides*, and *Saccolabiums* in particular become a prey to them. They never feed in the daytime, and are rarely seen during the daylight unless disturbed from their haunts; consequently they may exist in much larger numbers in any place than is supposed. By diligent hunting with a lamp after dark, some may be caught, but more will make their escape. Small pots, containing treacle and water mixed in equal proportions, placed about their haunts, are sometimes used. By such means some may be caught, as also by the different forms of traps that are sold for catching them; but with any means of this description in plant houses I was never able to catch them in sufficient numbers to keep them down so low as desirable. I have tried all the different kinds of poison sold for their destruction, including the phosphorus preparation usually employed. Any of these they will take for a time, and many may be destroyed by any of these preparations; but amongst them all, Roth and Ringiesen's Beetle Poison (obtainable through any druggist) I have found much more effectual than all the others. We lay it in bits, about the size of a small French Bean, on the smooth side of oyster shells, pieces of glass, or broken glazed crockery; it is necessary to use something that has a hard smooth surface that will not absorb the moisture from it, or it will be so dry, after the first night, as to render it useless. By using any of the above-named articles it will be fit for use for three nights, although the phosphorous it contains renders it of a drying nature. But this preparation must be used with caution, as domestic animals will eat it and be destroyed thereby. On the nights we lay it down we are careful to exclude the garden cats from the houses, or these most useful animals would come to an untimely end. When we lay the poison down in each house on an evening we count the bits, and chalk the number on a board or anything we employ for collecting them in the morning, which is always done the first thing, and put them away where they will not be exposed to the air. After using three nights the poison gets too dry for the beetles to take it freely. By using it once in three months, I am not troubled with the insects so as to do any serious harm; but where they have been allowed to get to such a head as we see them sometimes, it is necessary to keep laying down the poison every night for a fortnight or so, to bring them well under. I have seen a dwelling-house, in which the common black beetle literally swarmed by thousands, cleared by a few weeks' perseverance with this poison.

T. BAINES.

Rose Galls on Willows.—The accompanying twigs are cut from a Red Willow; and I should be glad to know what are the flower-like growths that have been formed at the extremities. Hundreds of similar examples are to be found on the Willows around my house.—J. O. D. [These curious galls or roses are produced by the larvæ of a minute but most elegant little fly or gnat, which is described by Mr. F. Walker at p. 77 of the third volume of his "*Diptera Britannica*," under the name of *Cecidomyia rosaria*. It causes these rosettes to be formed on five different species of the Willow—*Salix alba*, *S. caprea*, *S. aurita*, *S. cinerea*, and *S. depressa*, as we learn from Mr. Walker. With *S. aurita* we are imperfectly acquainted, and *S. depressa* we have never seen; but the three other species are common, and their rose-like galls at the termination of the shoots are very familiar to us, more particularly those on *S. caprea*, commonly called the Goat Willow—or, when the galls are abundant and conspicuous, the Rose Willow or Rosette Willow. De Geer was, probably, the first scientific naturalist who describes these galls. His observations occur at p. 155 of the sixth volume of his "*Memoirs*," published at Stockholm in 1752.—Ed.]—*Field*.

THE LIBRARY.

THE ART OF BOTANICAL DRAWING.*

AMONGST a number of books connected with art, published by Messrs. Winsor & Newton, intended chiefly for the instruction of beginners, we are induced to notice one which comes so naturally within our province that it would be an omission on our part to overlook so useful a contribution to our book-shelves. After a few remarks, in an introductory chapter, on the necessity for scientific knowledge, and the names of such books as will best help a learner, we arrive at the chief matter of which the work consists. Leaves, being the most obvious objects in connection with vegetation, form the first subject, and, respecting them, we have the sound advice to draw the mid-rib and lateral veins first, which method ensures far greater accuracy than commencing with some outlying part; the foreshortening of them then follows naturally and easily. The placing of

them on branches is next described, with the help of one of the illustrations with which the book is interspersed. Then we come to flowers, and a few good rules for their delineation, such as marking out a circle, and then its division into petals, whether foreshortened or not. After the regular flowers come the irregular ones, such as those of Orchids, of which some

nice drawings are introduced. We then pass on to fruits and seeds, and these terminate the instructions on simple outline. There are, however, other points touched upon, such as "enlarged details or analysis of flowers," and "arrangement," the latter subject being particularly well treated and illustrated. "Shading and colouring" next receive attention, and here the advice concerning the lighting up an object artificially, so as to get a good example of form developed by light and shade, is very much needed by many who are by no means beginners in their own estimation. Colouring

receives some brief attention, and then follows a short chapter on the highest point to be attained, namely, "the grouping of plants," represented by the Ivy, the Vine, the Rose, the Clematis, &c. From first to last, it is a most sensible and readable book. The accompanying illustrations afford an example of the manner in which a beginner

* "The Art of Botanical Drawing." By F. W. Burbidge. London: Winsor & Newton. 1873.

is instructed in the employment of geometrical figures so as to secure accuracy of outline in sketching fruits and cones.

BOTANIQUE POPULAIRE.†

THIS, although not a very new book, is one of the best elementary treatises on botany which have issued from the continental press. It forms a handy volume of over 400 pages

illustrated with 215 wood-cuts. The characters are well arranged, and the various subjects are concisely but clearly treated, so that we have no hesitation in saying that it is, of all the elementary works which we have seen on the subject of botany, at once the most succinct and comprehensive. Everything relating to the primary tissues and compositions of plants is well explained with diagrams, and, in the succeeding chapters, the nature of the epidermis or outward bark is well discussed. As regards the functions and powers of the roots to sustain or originate the life of a plant, the author has very well

disposed of his subject. We have not, at present, space to quote him at length, but the following extract, which relates to the flowering of various sorts of plants, may be worth noticing as an example of the style and matter of the work:—

In the case of most plants, and with all those whose flowers are disposed in a spike or cluster, the lower or outer flowers invariably open first, and the flowering proceeds upwards, as may be seen in the Wheat, Parsley, and Plantain. In other plants the central or terminal flower opens first; when it terminates the stem, there are generally two or more floral leaves at its base from the axils of which other blossoms spring, so that the inflorescence is formed of a series of dichotomous ramifications which are so dispersed that the central flower is the first to open. This arrangement may be observed in several of the Euphorbias, the common Sunflower, &c., but the order first-mentioned viz., that in which the outer or marginal flowers are the first to bloom prevails in by far the greater number of plants.

The numerous woodcuts which occur through the volume are remarkable for their exquisite finish and clearness of outline. They comprise not only explanatory figures of the structure and various parts of the inflorescence, frutification, &c., but also many well-executed portraits of the plants themselves, and enhance, in no small degree, the value of the work.

Diagram showing how Fruits, &c., may be sketched correctly.

Fruits and Seeds.

THE KITCHEN GARDEN.

NEW BROCCOLIES.

By WILLIAM TILLERY, Welbeck.

HAVING grown in quantity two varieties of Broccoli lately sent out, I can highly recommend them as being great acquisitions to all growers of this invaluable vegetable. One variety was sent out by Messrs. Watts, of Northampton, under the name of Excelsior; and the other by Mr. Cooling, of Bath, under the name of Matchless. They are both early, or, rather, mid-season sorts, having commenced this year with me to supply good heads by the beginning of March; but, owing to the mildness of the winter, all sorts of Broccolies are coming earlier into use than usual. Both Excelsior and Matchless are thoroughly protected by their leaves, and may be cut snow-white before the heads are exposed to the air; while their flavour, when cooked, is everything that can be desired in a Broccoli. When the heads come in too fast, the leaves can be tied over them to preserve their colour; and, either for growing for market purposes or for private use, these two sorts, in my opinion, will be found the very best in their season. Another new variety, sold under the name of the Leamington Broccoli, I am sowing this year for the first time; and, as it has been certificated by the Royal Horticultural Society, it ought to be of good quality. Some of the varieties of Broccoli, now so abundant in seedsmen's lists, require a thorough weeding out, for they differ only one from another in name. The following kinds are, I find, quite sufficient to keep up a regular supply and succession, when the winters are not too severe. With good management, the supply of Walcheren can be maintained well into January, when Snow's Winter White Broccoli (which is a good "strain" of Grange's Autumn) will come in, followed by Backhouse's and the Early Penzance. Osborne's Winter White has too much of the Cauliflower breed in it, and will not stand severe winter frosts in the midland districts. Dilcock's Bride and Frogmore Early Protecting are two good early varieties, to be followed by the Excelsior and Matchless. Knight's Protecting and Williams' Alexandra are also good sorts to fill up the gap until the latest Broccolies come in, such as Carter's Champion, Cattell's Eclipse, and Sander's White Goshen, which is the very latest variety that is grown.

MUSHROOM CULTURE.

By R. GILBERT, Burghley.

THE many letters that have appeared in our horticultural journals touching the growth of this valuable esculent makes it difficult to state anything new on the subject. Therefore, at the onset, I may remark I have little that is novel or sensational to offer. My object is to give some plain instructions, which, if carried out, cannot fail to ensure success. The three principal points of Mushroom culture consist, firstly, in working and turning the dung; secondly, in the forming of the bed; and, thirdly, in spawning, soiling, &c. These three points I shall try to describe in the order in which they are written, and finish by giving a few general remarks. Many Mushroom-growers are very particular in using clear droppings from the horses. If the market had to be supplied from such a source, the demand would be greatly above the supply. Experience has taught me that the dung brought fresh from the stable, with the straw mixed with it, makes the most lasting and best material. To make a moderate-sized bed, for a nobleman's or gentleman's establishment, four cart-loads will be required, which should be well shaken together in a round heap. If dry, pour on water as the turning proceeds, and, when finished, beat it down with the back of the fork, and put on a cart-load of any sort of soil, except rank clay; the best soil is turfy loam, but that cannot be got at all places. However, use the best you have, spreading it all over the heap to conceal the dung. In three or four days you will see the steam coming through the soil. It should then be turned over again, turning the outside into the middle, mixing the soil with the dung as the work proceeds. It will require turning twice more, at intervals of two or three days, when it will be in a fit state to form the bed, either for outside or edge beds or for the Mushroom-house proper. And let me

here remark that outside beds grow Mushrooms of far better flavour than those grown in inside beds, from which the Mushrooms are white in colour, insipid in flavour, and lack, in an eminent degree, the thickness of flesh and the wholesome partridge colour of the former. In fact, to use a market phrase, they are parasols in miniature. Therefore, I will suppose that outside beds are intended. After looking out the site (the best is a snug warm corner facing the south), begin by forming an equilateral triangle, 3 feet each side, putting in one stake at each corner of the bed, and it will be found that the quantity of dung prepared will make a bed from 12 to 14 feet long. One man should stand on the bed, while another puts on the dung, treading, beating, &c., until the required height of 3 feet is obtained. Place at each side of the bed, but not opposite, four trial sticks, covering all up with a mat. Be particular to feel the heat daily, and, when it is new milk warm, under rather than over, the time of spawning has arrived. If a bottom-heat thermometer is at hand, from seventy to seventy-five will be a safe guide. Buy the spawn from a first-rate firm, and you will not be deceived. Break it up into pieces the size of a pullet's egg, and insert the pieces 2 inches deep in the dung, and 12 inches apart on both sides of the bed. Beat the surface down smoothly with the back of a spade, and cover up with matting to keep out the wet. The soil should not be put on for two or three days. By using this precaution, you have the heat well in hand; occasionally, a second heat gets up, and burns the spawn, if this is not attended to. In earthing up the bed, common garden soil is used, which may be dug from the ground on each side of the bed. Lay it on at least two inches thick, and beat it firmly. If the soil is wet, and you cannot get a smooth surface, put on a sprinkling of sand before beating. Cover up with a layer of 3 or 4 inches of long dung, and put a mat over all, and, in about eight weeks, you will be rewarded with a sight worth seeing, and a dish of Mushrooms worth eating.

The best time to make the beds is from September to January, which will keep you supplied until May. After that time, Mushrooms are always attacked by a small insect, which makes them unwholesome. Water should be used with great caution; in fact, if kept covered, they seldom require any; exceptionally high and dry winds, however, render watering necessary. It should be given with a very fine-rosed syringe, and should have the chill taken from it before it is applied. When the beds begin to wane a second crop may be had by watering with dung water, mixed with common salt, at the rate of 1lb. to a gallon of water.

FRENCH MODE OF CULTIVATING WATERCRESS.

THE water from springs has been utilised in the cultivation of this plant, which was first commenced in the neighbourhood of Senlis, on the banks of the Nonnette, in the beginning of the present century. The ground in which the Watercress is cultivated is situated below the spring which feeds it. Across the slope a series of trenches is dug which communicate with each other, and the flow of water is regulated by little sluice-boards placed at the point of communication. The trenches having been completed, and communication with the spring cut off by the first sluice-board, the Watercress is sown in spring at the bottom of each trench, which has been previously cleaned out, and from which every aquatic plant that might prove injurious to the crop has been removed. Instead of sowing, some cuttings might be planted in August in the bottoms of the trenches, after the ground has been moistened by admitting a gentle stream of water. These cuttings are placed 5 or 6 inches from each other. In a short time they take root and the plants soon cover the surface; the sluice-boards are then raised, and water is admitted to the depth of 5 or 6 inches, which will be found sufficient. If the plants have been well taken care of, well selected, and well cleaned from every parasitical incumbrance, the Cress-bed, once established, requires no other care than to be guarded from the frost. In order to do this, the water is allowed to rise and cover the Cress while the frost lasts; but, as soon as the weather becomes mild, it must be let off to its former level, as continued submersion injures the plants. There should be an outlet from the spring not communicating with the Cress-bed,

which should be opened in times of thaw or heavy rains in order to prevent the trenches being overflowed to the detriment of the plants. It is a good plan to protect the trenches from cold and heat by means of hedges planted in the intervals between them, but the leaves from these hedges should not be allowed to get into the trenches, otherwise the Cress will be smothered and cannot grow. This evil may be prevented by fixing a trellis or mats on each side the hedges. The Cress is gathered by placing a strong plank across the trench; the Cress may be cut with a pruning-knife, but it is better to nip the shoots off with the thumb-nail one after another, as by this method the plants are not disturbed at the roots.

During summer, as long as the season is favourable, a trench may be visited, and the plants cut or gathered every three weeks; but, if the season is cold, we must wait two months before making a second cutting. When the gathering for the year is over, the trench is left dry, and a light layer of well-decomposed cow-dung is spread over the entire surface, after which the plants are pressed down with a plank, which has a long handle at each of its extremities. Two workmen take this implement, and, as they go from the end of the trench, press down the plants which have been raised at the times of gathering. A Cress-bed will last a long time if carefully managed; but, as it is seen to be running out, it should be renewed. In doing this, the plants are pulled up by the roots, and laid on the spaces between the trenches; the trenches are then dug over, and manured with well-decomposed cow-dung; after which the Cress is replanted as at first. Some growers take up the plants every year, remove the mud from the trench, dig the bottom over and manure it, after which they replace the old plants. For supplying water to, and emptying, the Cress-beds, stoneware pipes 3 inches in diameter are used. The water must be allowed to run freely, if it is desired to have Cress of a good quality. The sluice-boards are only used to stop the water in frost, and to let it off during a thaw or heavy rains. The seed is gathered from the finest plants in each trench in August. It keeps good for four years.

Yellow Cucumbers.—Could you inform me what makes my Cucumbers turn yellow? They grow well to about 5 or 6 inches long and then drop off. The foliage is very healthy, and the plants make growth freely. I have "set" the flower? Do you think the evil is due to the situation of the house, which is east south-east, shaded from the south by another house?—VIOLET. [Cucumbers turning yellow at this season of the year may arise from various causes. If the plants are as strong and healthy as described, it cannot be through want of vigour; yet, even if they are apparently healthy, if too much water is given at the roots, it would have the effect of stopping the fruit from swelling freely. A dark unsuitable situation, with the house shaded by another, as described in the present case, would produce the effects complained of. The finest of some of the varieties of the Cucumber, especially the large-growing kinds, are very subject, if used for winter-work, to turn yellow. Small, or medium-sized varieties, such as Rollisson's Telegraph, are the best. I have never found any difficulty with this sort in getting it to do well in the winter season, provided a night temperature of 65° can be maintained, with a rise of 10° by day, and a bottom-heat of 75°, using good loam with a small quantity of rotten dung added. Deficiency of water at the root will prevent the fruit from swelling freely; but, in this case, it generally curls and thickens prematurely at the end. In the case of your correspondent's Cucumbers, from the description given, I should be inclined to attribute their unsatisfactory condition to the house being, from its position, deficient in light (for winter Cucumbers the house should be as light as possible, and placed so as to catch every ray of sunshine we get), or that the sort is not suitable for growing in winter.—T. BAINES.]

Leaky Watering-pots.—Gardeners are not unfrequently incommoded by leaky watering-pots, and it often happens that there is no tinman near at hand to mend them. M. Alégatière, the well-known nurseryman of Montplaisir-Lyon, states, in the *Revue Horticole*, that such leaks may be effectually stopped by covering them with a small piece of linen which has been previously dipped in copal varnish. The inside of the watering-can should be thoroughly dried, before the varnish-saturated linen is applied to the leak, when it is allowed to dry in the open air. The can will then be found perfectly water-tight.

SOILS AND FERTILISERS.

LIQUID-MANURE FOR POT PLANTS.

THE beneficial results obtained from manure-water, when judiciously applied to fruiting and flowering plants, have long been recognised by cultivators, and its use is now becoming more general. It is well known that the roots of plants are usually more healthy when growing in pure soil free from rank manure, and these roots will draw up more healthy nourishment to the plants from manure given in liquid state, than when they are encased in rank material which they cannot consume. We know that our most successful Grape-growers use very little solid manure in the soil, only a few bones or bone-meal or similar material, which cannot give off more stimulant than the plants can consume, and also remains much longer in the soil as a fertiliser than manure, which dissolves rapidly. Pine-apples are not grown by successful cultivators in that rich stuff so much prized by some of our forefathers. The successful florist has more faith in giving stimulants when the plant really needs them than in keeping the roots buried in soil made rich and almost offensive by strong manure. When roots are few, and the plants almost at rest, the purer the soil and the less stimulant the plants receive, the better will they thrive when their roots come to draw up larger supplies of nourishment. Moisture is needed to soften the soil, and to allow the roots to extract nourishment from it; but when all the virtue is out of the earth, and the plant begins to show signs of distress, all the watering in the world will not give vigour to the exhausted functions, but let a portion of guano or any well-prepared manure be mixed with the water sufficient to colour it, and let this be repeated at every watering instead of giving a much stronger dose at longer intervals, and the result will be most satisfactory. I have tried a number of experiments this season with liquid-manure, and all lead me to have faith in the application of it, at every watering, in a weakly state.—A number of fruit trees in pots (chiefly Plums) which had not been shifted for years, have produced heavy crops of fine fruit, and, though there was little in the pots but roots, frequent doses gave them all they required.—A number of old Fuchsias were stunted and pot-bound, but pressure of more important matters prevented our potters shifting them into fresh earth; but to each watering a colouring of guano was allowed, and the plants, with their pot-bound roots, have not only made vigorous growth, but flowered freely from June onward till November.—Some Pelargoniums, which were cut down last season and allowed to break in the usual way, were shaken out of the pot and placed in smaller ones, but, when they should have been shifted, they were allowed to remain in the small pots, which were crammed with roots; guano-water was given at all times when they required moisture; the plants grew and made fine foliage, and flowered better than others which were favoured with larger pots and fresh soil. Many other examples I could give to prove that giving liquid-manure frequently, and not till roots are in abundance to consume it, is the proper way to deal with this important assistant to cultivation.—*Florist.*

Preparing Bones for Fertilisers.—It frequently happens in country places, where bones are plentiful, that there are no mills to grind them, and, if applied to the land as they are, they decompose so slowly as to be of comparatively little use. In such cases chemical means, which are always at hand, are to be brought into requisition. Of all the various means that can be employed for decomposing and dissolving bones, the best and most practicable is wood-ashes. They are generally plentiful in country places—they prevent any unpleasant odour from being given off, and, above all, cause a rapid and complete decomposition. The bones are converted into a fine powder, which, mixed with the ashes, furnishes an excellent fertiliser, rich in potash and phosphoric acid. The method of using them is as follows:—A trench 3 or 4 feet deep, and of any desired length, is dug in the earth, and filled with alternate layers of ashes and whole bones, each layer being about 6 inches thick. The lowest as well as the top layers are of ashes, and each layer of ashes is thoroughly saturated with water. At distances of 3 feet poles are rammed down to the bottom of the ditch, and every eight or ten days they are taken out, and enough water is poured in the holes to saturate the ashes. At the end of two months the whole heap is thoroughly stirred up with a fork so as to mix the ashes and soften the bones, which are then left to ferment again, water being added as often as necessary. In about three months more, the heap being worked over twice or three times, the decomposition of the bones will be so complete that only a few of the largest remain, and these are taken out and put in another heap. This method of using bones comes to us from Russia, and is very highly recommended. The action of this fertiliser upon crops is said to be something extraordinary. It seems as if the salts in the

bones and those in the ashes unite to form very soluble salts which can be at once assimilated by the roots of plants. Where wood-ashes are scarce, recourse must be had to horse manure. The bones are soaked a few days in water, and then placed in rectangular pits with alternate layers of horse manure, each layer being drenched with the water in which the bones were soaked. The strata of bones are three inches thick, and those of manure a foot thick. The pit is covered with earth so as to be tightly closed. The decomposition of the bones will require, in this case, about ten months, when the mixture is ready for use as a fertiliser. They may, also, be more speedily prepared by boiling in the following manner:—Mix them in a large vessel with wood-ashes; and, to make the ashes caustic, add about a peck of fresh lime to each barrel of bones. Saturate and cover the ashes well with water, and then apply heat, for, say, twenty-four hours, or, during the day for two successive days. All the bones, by this time, except the very hardest parts, will be so reduced as to be easily pulverised, being in a pasty condition, suitable for placing in layers in making the compost heap. Another day's boiling will reduce the remainder of the hard bones. It is useless to recommend converting them into home-made superphosphate by using sulphuric acid; the difficulty and trouble in procuring the acid away from cities, and the care and experience required to use it, are sufficient objections.

THE JUTE PLANT.

(CORCHORUS.)

PERHAPS no vegetable product has been more rapidly introduced into general cultivation and has acquired greater importance during the past thirty years than the Jute-plant. The material for the account of it which we here present has been mostly obtained from *Science Gossip*. Jute is a fibre obtained from the inner bark of two species of plants belonging to the natural order Tiliaceæ, an order which is represented in our country by the Linden tree, from which most of the covering and tying material, well known to horticulturists as "bast matting" is obtained. The two common Jute-plants are *Corchorus capsularis* and *C. olitorius*, the former being generally considered the more valuable. The plants are annuals, growing from 4 to 12 feet high, according to the quality of the soil and the location, the stems at the base becoming an inch or more in diameter. The leaves are alternate, lanceolate in outline, toothed on the margin, with the lower pair of teeth prolonged into a slender thread. The flowers are small, half to three-quarters of an inch in diameter, yellow in colour, having five petals and a large number of small stamens. The fruit consists of a capsule, which in *C. capsularis* is nearly round, and in *C. olitorius* cylindrical and narrow. These capsules contain many small seeds. It is sown at different periods, according to the climate and variety, usually in April or May, and it flowers in July or August, when it is ready to be cut for the fibre. In Louisiana two crops have been obtained in one season. If cut at the first commencement of blossoming, the plants are more easily cut, and furnish a finer fibre than if left to mature. It is said that in India the stems or stalks of the Jute are of almost equal value with the fibrous portion. They are beautiful white and straight stems, of a light brittle wood, somewhat like Willow switches, and have a multitude of uses among the natives, such as for the manufacture of gunpowder and fireworks, for the making of fences and inclosures, for Pea-brush, and for the construction of those acres of basket-work which the traveller remarks near every native village. The thick and coarse butts of the older plants are cut off for about 9 inches. These butts are sold to paper-makers, and wrought up into coarse thick fabrics. The Jute fibre as prepared for the market, has much resemblance to that of Hemp, but is softer and more glossy, and under the microscope, more transparent and slender, and apparently with thinner cell-walls. The principal employment of Jute in India is for the manufacture of gunny-bags. These are the common coarse bags in which Indian produce is sent to market. They are also extensively used in the shipment of agricultural products in this country. The manufacture of these bags is an industry which pervades all classes in Lower Bengal, and penetrates into every household. Men, women, and children find occupation therein. Boatmen in their spare moments, husbandmen, and domestic servants, everybody, in fact, pass their leisure moments, distaff in hand, spinning gunny-twist. All the finer and long-stapled Jute is reserved for the export trade, while the short-staple serves for the local manufacture of gunny-bags. The export of Jute from India has rapidly increased during the past twenty years, and now reaches nearly 3,000,000 bales.

The use of Jute as a paper material will greatly increase the commercial value of this valuable fibre. The *Dundee Advertiser*, on its appearance printed on Jute paper, after apologising for its transparency and thinness, says:—A remarkable fact is that it is the

product of Mr. Watson's second experiment, and if we can attain to such a result on only a second trial there need be no fear with respect to further experiments. The thinness and transparency will easily be remedied, as there is nothing to prevent paper made from Jute being of any degree of thickness and opaqueness. It may be explained that this sample is made almost entirely from old Jute-bagging. We propose to have samples made entirely from Jute-fibre. To some extent Jute-bagging and waste have been used by paper-makers for several years, mixed with other materials; and when we mention that nearly 50,000,000 Jute bags were exported last year—the demand for home requirements being also very large—it will be seen how large a quantity of manufactured Jute there is to work upon, especially as bagging is only one class of the goods made from this material.

WORK FOR THE WEEK.

Flower Garden.

STIR the soil occasionally amongst spring-blooming plants, and if slugs are troublesome scatter some air-slaked lime around the outside of the beds in which they are growing. Edgings of *Stachys lanata*, *Cerastium*, variegated *Thyme*, *Gnaphalium lanatum*, variegated *Arabis*, variegated *Queen of the Meadow*, *Aucuba-leaved Daisies*, crimson-leaved *Ajuga*, the dwarf *Campanulas*, *Santolinas*, and a few other compact-growing plants may now be lifted, divided, and transplanted. Two-year-old edgings are generally better than one, so that unless they exceed that age, they are better left undisturbed. The variegated *Polemonium caruleum* makes one of our finest hardy edgings; the best way of treating it is to lift the roots and pot them in October or November, to keep them during the winter in a frame or cool Peach-house, and transplant them in spring when they begin to grow. Transplant from frames, green-houses, or pits, into beds in the flower garden, *Pinks* and *Carnations* wintered in pots, or autumn layers planted in light soil in frames in winter. Bulbs of *Lilies*, yet in store should be planted as speedily as possible. *Pansies*, and other spring-blooming plants, may yet be transplanted as occasion requires; indeed, few plants are more useful at any season than *Pansies*. *Gladioli*, for blooming in beds or shrubbery borders, may be planted at once 3 or 4 inches deep, and a sprinkling of sand should be strewed under and over the bulbs. It is a prevalent idea that *Gladioli* should not be transplanted till May, for fear of spring frosts; but that is too late, unless the plants are required for late flowering. Sow *Mignonette* where it is required to bloom, and hardy annuals not sown last September here and there in beds or borders for transplanting. Sow also a good stock of *Sweet Peas*, *Nasturtiums*, and *Scarlet Tom Thumb Tropæolums*, either where they are to bloom or in sheltered beds or corners for transplanting hereafter to their permanent quarters. Autumn-saved roots of *Scarlet Runners* throw up shoots freely, and bloom earlier than seedlings; the roots require treatment similar to that usually given to *Dahlias*. Divide and transplant roots of herbaceous plants of various sorts. If worm-casts are prevalent on lawns, prepare some lime-water, mixing therein some soot and salt, and water the lawn with the mixture through a rough rose; this not only gets rid of the worms but invigorates the Grass. Pieces of ground about to be converted into lawns should be turfed at once, or, if turf cannot be obtained, they should be thickly sown down with Grass seeds. Hollows or other irregularities should be made level at once. In such operations the turf should be carefully skinned off and used again, for in no case should patches of new Grass be visible on permanent lawns; the more prominent portions of lawns will have been already mown this season, but now the whole of the Grass-surface should be cut. It should first be gone over with a wooden-toothed rake, and *Beech nuts*, small stones, and other things detrimental to the scythe or mowing-machine should be removed by means of a *Daisy rake* or a *birch-broom*. After that well roll the Grass previous to mowing. *Plantains*, *Dandelions*, *Daisies*, and similar plants the riddance of which from lawns is a desideratum, may now be eradicated. If Moss prevails amongst the Grass, rake the roughest of it off, and apply a dressing of sifted soil over the whole surface, which will so stimulate the Grass so as to make it choke the Moss.

Indoor Fruit Department.

Peaches, Nectarines, Plums, and Cherries will now be in full bloom, and plenty of air must be given them on all favourable occasions. See that the soil in the pots is kept moist, but not soddened, for the trees often drop their fruit when young under any excess of moisture or dryness. It is a good plan to retard a few dozens of these kinds of fruit-trees in pots, as they will flower later, and furnish a succession of fruit. As soon as the Grapes in the early house begin to show colour, a drier atmosphere may be maintained, and air given

liberally. Water freely the inside borders of the succession-houses, and see that the protecting materials on outside borders still maintain their efficiency. Owing to the winter being mild and open, the buds of the Vines in the latest houses will be swelling; and fire-heat, where available, should be applied, so as to get the Grapes ripe in September: they will then keep far better than when ripened in October or November. This is one of the great advantages belonging to the plan of bottling late Grapes; for the Vines can then be properly dressed, and forced earlier than they otherwise would be. The earliest house of Peaches and Nectarines will now be nearly past the stoning process, when a rapid change takes place in the swelling of the fruit; but, before this takes place, it must be thinned if too thickly set, as no more will drop off. If the trees are in good health, the fruit on them may be regulated from 6 to 8 inches apart at this last thinning. When it begins to colour, air may be given freely, and the temperature may rise to 75° or 80° by sun-heat. Succession-houses will want syringing daily, and attention must be paid to watering the inside border; for, although the surface may look moist, underneath they may be as dry as dust. Tying down the shoots as they progress, and thinning them gradually where not wanted, keeping aphides and red spider in check, will be routine work now for some time in the late houses. Keep Figs well watered and syringed daily, as red spider is a great pest to them. When the fruit begins to ripen, watering must be gradually discontinued. Stop all shoots when 6 or 8 inches long, in order to encourage a second crop. The earliest forced Cherries will now bear a higher temperature; but plenty of air must be given in the daytime, to colour and give flavour to the fruit. The supply of water at the roots must likewise be lessened for that purpose. Plenty of heat, together with light, air, and moisture, will now be required for Cucumber and Melon plants, and the shoots must be regulated frequently, by stopping and pruning them, so as not to get too crowded. A steady bottom-heat must be maintained to Melons till they flower; and, after plenty of fruit is set, liberal supplies of tepid water may be given to the roots. Sow good batches of seed of both Cucumbers and Melons for a late supply of plants, and some of the Ridge variety of Cucumber for planting out in the open air. Where plenty of room can be had in frames or in low pits, the remaining batches of Strawberries in pots may now be put in them to flower, and then be taken into the forcing-houses, as required, for succession.

Kitchen Garden.

From the crowns of Globe Artichokes remove all weakly suckers; strong grown ones, intended for new plantations, may also be carefully taken off with a root or piece of the crown and planted in lines, two or three plants, a few inches apart, being put in together, so as to enable them to have a Seakale pot put over them for a while, until they have become a little established or sheltered with boughs. As regards Asparagus, those who practice the blanching system should finish the covering of their beds. Plants grown on the level-ground plan in single rows, the alleys between which were manured and forked in the autumn, and stirred up with a strong hand scarifier, should be kept frequently surface-hoed and freed from weeds. The time has now arrived, if the ground has been brought into proper condition by means of previous deep trenching, heavy manuring, and additions of good surface-soil, decomposed vegetable matter, Seaweed, &c., for new plantations to be made. For these, choose the strongest plants that can be got from the seed-bed when they have made a few inches of growth, and having the ground levelled and in readiness to receive them, mark it off into distances of 2 feet apart. This may be considered by some to be too close; but the plan is to lift, when two years old, every alternate row for forcing, thus leaving the permanent lines 4 feet apart. In planting, stretch the line, and draw deep on drills each side of it, thus leaving a ridge just under the line. Across this ridge place the roots systematically astride, and cover them over from both sides. This is a more natural mode of planting than taking out a notch on one side of the line only, and laying in the roots fan-shaped, as it prevents any undue huddling together of the fibres. Asparagus seed may also now be sown thinly in drills, and, as soon as up, thinned by hoe or hand; using the hoe frequently among the young plants, to stir the surface and keep it open. Of Broccoli, Brussels Sprouts, Borecoles, Savoys, &c., make other sowings, to succeed those made last month, the produce of which, if big enough, should be pricked out a few inches apart. Make small sowings of Coleworts once a fortnight, in order to keep up a succession. Little Pixie, Matchless, dwarf York, and the London green Coleworts are best for this purpose. Earth up Cauliflowers, and cover the surface about the roots with a mulching of short dung or litter; leave, also, a basin round those that have had over them hand-lights, in order to supply them with soakings of manure-water. Prick off spring-sown plants, and, when fit, plant them out in succession in cool shady places. Sow Veitch's Giant in succession for late summer and autumn use; these

should be planted in partially-shaded places, such as between rows of tall Peas. Sow Carrots once a fortnight till the middle of July, in order to have nice young roots throughout the season. Of Celery sow a main crop on a slight hot-bed, and prick off the plants as soon as they are fit to handle, into a well-pulverised rich soil, such as a compost of equal parts decayed mulchings, leaf-mould, and half-decayed turfy loam, chopping the whole rather finely, and mixing all well together. Towards the end of the month the plants, which by that time will have become strong, may be pricked out on an open border, using the same compost, or a layer of it laid down to the depth of 6 or 8 inches, on a hard bottom. The latter prevents the roots from penetrating too deeply; they, therefore, can be lifted the more easily, with good balls for transplanting permanently. Protect, if necessary, and supply water plentifully. Sow Chervil in small quantities once every two or three weeks throughout the summer, on cold north aspects. Sow Lettuces in drills; thin, and, if necessary and the weather favourable, transplant the thinnings. Thin Onions in beds or lines, and fill up any vacancies by timely transplanting; hoe and surface-stir frequently, in order to maintain a healthy and vigorous growth. Of Peas, sow tall kinds in succession, and run a wide-toothed rake across the drills of those just coming up; draw little ridges of soil about 6 or 8 inches from the sides of the lines, in order to admit of a mulching of litter being administered, and to retain soakings of water that may be given in dry weather. Sow Round Spinach in succession in cool situations throughout the summer; plant out New Zealand Spinach, and encourage the strong winter kinds by frequent stirrings. Sow Turnips in succession, in drills, in cold moist soil for the next two months. Harden Tomatoes off, and prepare for planting them out by the beginning of May. Preserve a few plants in small pots, and expose them all summer, in order to obtain from them some short, stubby cuttings, for early fruiting next season. The older Tomatoes are the shorter jointed and more fruitful they become. This treatment is also applicable to the Cape Gooseberry. Sow Sweet Basil and Marjoram in succession; prick off those already up, and grow them on in gentle heat. Sow Angelica for next year's crop, in rows 2 feet apart. The first lot of stalks should now be ready, and should be looked too before they become too hard and strong. We too often find the herb-ground in a comparatively dilapidated condition. It should, however, now be neatly trimmed, and any blanks that exist in it should be made up. Sow Borage and Burnet, and transplant last year's plants of Fennel. Lift the roots of Horehound, and divide and transplant them. Lift young plants of Hyssop, Lavender, Rue, Savoury, &c., and re-plant them in beds, and put in another lot of cuttings. Sow seed of the common Thyme, and plant out that previously sown. Layer and plant out singly Lemon Thyme and Sage. Make new plantations of Tarragon; removing with a knife the young shoots a little under ground, and preserving to each some rootlets; plant out in rows a foot apart. Mint of various kinds treat as Tarragon, and top-dress the beds an inch or two in depth with rich earth or leaf-mould. Camomile, divide the roots, and transplant in rather moist and shady places. Make new plantations of Tansy, Pennyroyal, Balm, &c. As regards Mushrooms, obtain good manure, fresh from the stables, and incorporate it thoroughly with sound adhesive loam, in sufficient quantity to prevent its heating violently, and thus becoming over dry. It is by imprudent over-heating that so many growers fail in producing Mushrooms of firm and useful substance, good flavour, and lasting as regards crop. The most successful place for growing Mushrooms during these next six months is in cold cellars, and other places with north and shady aspects. In such situations they are not so apt to become infested with maggots, as they otherwise would be if occupying a sunnier position; but precautions against these marauders are always necessary. To the surface of the beds now in bearing, and those just showing, if dry and crusty, give a little tepid manure-water, manufactured only from the dung of cattle, sheep, or deer. It is seldom Mushrooms are required to be grown artificially in the late summer months, when they can be procured from the fields.

A New Fibre.—A short time ago my attention was called to a sale of fibre of a novel description which was brought to this city from the South Sea Islands. This fibre was at least 7 feet in length, very strong, and apparently suitable for any purpose. I was, at first, puzzled to know what plant could yield so valuable a material, which was described as having been obtained from the stem of a tree growing in great abundance near the sea-shore. Fortunately, there was on board the vessel which brought the fibre, a portion of the so-called stem, which proved to be the adventitious root of a species of Pandanus, and constructed almost wholly of fibre. It is expected that large quantities of this new material will soon be imported here.—CHARLES MOORE, *Botanic Garden, Sidney.*

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ROSES.

By S. REYNOLDS HOLE.

ALTHOUGH the winter seems to have been unusually propitious, the late frosts have so effectually checked the precocious growth, which was seen in the Rosarium before their influence was felt, that, here in the Midlands, we are much more backward than in an ordinary season. The Briars, planted last October, are only just breaking, and some, as yet, have made no sign. The seedling Briars are more demonstrative, and this will, I think, always be the case, because their abundance of roots will render them far more powerful to resist the vicissitudes of weather. People who have recently had a few of their toes amputated do not stand quite so securely as those do whose feet are intact, and the wonder is how those stocks, "yarked" out of the hedge-rows, thrive so robustly, and produce such glorious Roses, as they generally do. The Manetti Stocks are more forward, and so are last year's buds upon the Manetti, coming through the soil like Asparagus heads, and making the buds on the Briar look "quite emancipated" (as a talkative hair-cutter once described to me a poor boy who had been starved by his parents), when compared with their obese proportions. It does not follow, however, that the Manetti Roses will surpass in 1874, as they did in 1873, the Roses on the British Briar. Happiest is that Rosarian, who has his favourites in all forms, on the Briar (standard or seedling), on the Manetti, and on roots of their own. This year's list of new Roses is before me, and I infer from it that the French growers have hardly yet recovered from the interruptions and destructions of the war. Their number is not so large as it should be, but the well-known names are there—Lacharme, Eugène Verdier, Ducher, Levet, Damaizin, Guillot, Liabaud, Levêque, Jamain, Vigneron, Touvais, Schwartz; and these inspire pleasant hopes. And it is gratifying to observe that the spirits and confidence of "our lively neighbour, the Gaul," are not broken by his reverses, and that he is quite capable, as in the olden time, of doing full justice to his Roses in speaking of their merits to his friends. These seem, as usual, to be all that eye or nose could wish—very large, very full, very lovely in colour, and perfect in form. They are "incomparable," "most effective," "dazzling," and "superb." Somehow, we old fogies do not find ourselves quite convinced, having reached that stern epoch of existence in which it becomes necessary, before our eyes are "dazzled," to have a peep at the sun. In the meantime, I have only to say that I hear, from trustworthy brethren, very favourable reports of Lacharme's Captain Christy, and that I shall shortly have reliable descriptions of other novelties, which shall be communicated to THE GARDEN. Blooms of two new Roses have been sent to me for inspection, both bearing the same name, Duchess of Edinburgh; but as different from each other as Roses well could be. The first which reached me is a hybrid perpetual from Mr. Bennett, of the Manor Farm Nursery, Stapleford, Salisbury, and is a beautiful large blush Rose of the Marguerite de St. Amand type, very full of petal, symmetrical in form, making healthy vigorous wood, with fine fresh foliage and delicious fragrance. The second is from Messrs. Veitch, of the Royal Exotic Nurseries, at Chelsea, a bright cherry-red Tea Rose, quite distinct and new, evidently of free growth, and sure to yield abundant Roses of great value for decorative purposes. We shall see it a favourite in Covent Garden Market by-and-bye, in button-holes and bouquets, in the Rose-house and the conservatory. Mr. Bennett also sent me flowers of a charming Tea Rose, Madame François Tanin, in colour a bright orange—a real *bouton d'or* for the coat. Roses under glass are blooming excellently. My best are the Maréchal, Marquise de Castellane, La France, Mdle. Eugénie Verdier (these two *belles* of the Rosarium seem always to be meeting in rivalry, but I most admire the first), François Michelon, Paul Neron, &c. Souvenir de Poiteau and Charles Turner are very good Roses to force.

OUR FRUIT PROSPECTS.

ANOTHER mild winter and spring, with a few sharp frosts in March, have resulted in the general wreck of the Apricot crops, and the injury of many of the forward blossoms of Peaches and Pears. As to Peaches, they have, upon the whole, escaped better than might have been expected. They were later, and they are also hardier, than Apricots. Structurally, the blossoms seem very much the same; but their distinct and differing powers of endurance have long been noted. It would be interesting to discover how much of the Peach-blossoms' extra power of withstanding cold is owing to their bright colour. Paleness and tenderness often go together. Two lessons all fruit-growers should study. One is the importance of getting trees to flower late in the open air, and the other the necessity of providing more efficient shelter in the spring. Something may be done towards the first by a partial change of aspect. May we not be wholly wrong in invariably giving Peaches, Nectarines, and Apricots, a south or west wall? The result is a maximum amount of heat, often at the wrong season. The trees live, in March, between fire and ice. Now the sun beats upon them, and their sap flows forth with a rush, impelled by a mid-summer heat of from 70° to 90°; within a few hours a mid-winter frost chills and freezes their juices—15° of frost—a difference of, it may be, over 70°. Under such extremes as these, is it any wonder that the tender blossoms succumb? On an east or north-west wall, the trees would be colder, it is true, but they would, also, be later; and this lateness would prove their safety. The idea seems to have prevailed that our trees cannot be active too early. This is wholly a mistake. They gain nothing by being excited so early in spring. Our summers are long enough and warm enough to ripen Peaches and Apricots, did they not flower till the middle or end of April. It is not by a series of starts and checks that good fruit is perfected; but by a process of constant and cumulative growth. The latter would be the result of a late start. Some of the finest Apricots I ever gathered were the produce of an east wall. They bloomed late, and never missed a crop; and the flavour was superior to the half-baked produce of walls facing due south. Further, we want strains of late-blooming Peaches, Plums, Nectarines, Apricots, and Pears; not later sorts, but later bloomers, as distinguished from late varieties. Here is a new field for hybridisers, in which each week abstracted from the season of flowering would be a clear gain to practical horticulture. Mr. Rivers has done much to extend our season of superior fruits at both ends, by giving us earlier and later, as well as superior, varieties. I hope he may at some time turn his attention to the procreation of late-flowering varieties, as I know of no one so likely to succeed in the matter. Already we have considerable difference in the time of flowering; and, by working with the latest kinds, later and yet later might still be produced. Another point of importance would be any additions to the substance of the flowers themselves. There are great differences in the self-protecting forces of the flowers of fruit-trees, and the slightest addition to these is of more service than almost any amount of external or extraneous protection. But, so long as later-flowering varieties of fruit-trees, stronger, better guarded, and, therefore, hardier flowers, are desiderated, there cannot be a doubt but that we must have more efficient shelter if we are to carry our fruit safely through our springs. We need, at least, glass-copings, or glass-cases, or glass-houses to ensure outdoor crops. Of most of these I have written in former seasons, and need not enlarge on them now. Glass copings I found the best protection against 15° of frost during the month of March last. They are 18 inches wide, and slip under the copings of the walls. Under them, Apricots, in full flower, have preserved a fair crop; while other trees, not so sheltered, have failed. Peaches seem, also, quite safe. Still, in addition to these modes of protection, and also as a substitute for them, I would recommend flued walls in all cases of erecting new garden walls. They need add but little to the expense, and, of course, the fires would not be lighted unless needed. But, during exceptionally cold weather in the spring, or wet, comparatively sunless, autumns, the application of a little fire-heat behind the trees would prove the means of safety to the blossoms and of perfect maturation to the fruits.

D. T. FISH.

NOTES OF THE WEEK.

— WE have received *Primula denticulata pulcherrima*, beautifully in flower, from Messrs. Backhouse, of York. Its flower-heads are as round as balls, fully 2 inches in diameter and as compact as those of a Guelder Rose. Individually the blooms are much larger and more richly-coloured than those of *P. denticulata*. Altogether it is a fine addition to our outdoor Primroses.

— THERE is now a fine display of hardy spring-flowering Alpine and herbaceous plants in the Royal Exotic Nursery, Tooting, both in pots and in the open borders. Scarcely any other classes of plants better repay careful cultivation than these, or cost less to grow them in perfection, and we are glad to see them rising once more in popular favour.

— THE transformation works in Leicester Square are now in a very advanced state, and are still being pushed rapidly forward. Already has the whole of the turfing been laid down, and the walks have been marked out, while, among various other operations in progress, a number of stone-cutters may be seen busy chiselling the stonework of the great central fountain.

— THERE are no fewer than 160 varieties of Plums growing in pots in the Royal Horticultural Society's Garden at Chiswick, and most of the trees are now profusely in bloom. This collection is a valuable one, and if, as may reasonably be expected the trees bear well, a comparison of their habits and fruits will, doubtless, furnish some valuable information concerning our different varieties of Plums; due allowance, of course, being made for the restricted conditions under which they are grown.

— A BRISK trade in dried Potatoes has lately sprung up in America. They are sliced up and dried in much the same manner as dried Apples. One firm in Rochester has an order on hand now for 50,000 pounds of these dried Potatoes, as well as for 1,500 bushels of Onions, which are dried in much the same manner. They are intended for the navy. A bushel of Potatoes dries away to about ten pounds, and a bushel of Onions to about six pounds. When ready, they are put into large tin cans, holding about forty pounds each, and sealed up the same as oysters.

— ON Tuesday next, the 21st inst., a special meeting of the Fellows of the Royal Horticultural Society will be held at South Kensington for the purpose of taking into consideration the expediency of conferring (as has been proposed) upon male Fellows the power of voting by proxy. The question is one of high importance to the interests of the Society, and, as very great diversity of opinion is known to exist amongst the Fellows respecting it, there can be little doubt that it will form the subject of a very lively discussion, the result of which will be anxiously looked forward to by both sides.

— THE New Chelsea Embankment is to be opened on the 1st of May. The indispensable portions of the work are now completed, and the ornamental portions are being rapidly pushed forward; the entire length, extending from Battersea Bridge to Chelsea Old Bridge, has been planted on both sides with rows of Linden trees. The mud-banks fronting Cheyne Walk, and extending from Queen's Road to the Albert Bridge, and thence to Chelsea Bridge, 700 yards in length, are laid out in Grass plots and flower-beds, planted with bulbs, roots, and flowering shrubs.

— AT the meeting of the Royal Horticultural Society on Wednesday last, Mr. Denning exhibited three very large-flowered *Masdevallias*, viz., *M. Harryana*, with enormous blood-coloured sepals, tinged with purple, the lateral sepals being nearly 3 inches long, and about as much across. Another variety, slightly smaller, seemed to form a connecting-link between this beautiful but variable plant and *M. Lindenii*, a plant of which was also shown for comparison. This intermediate form convinced us that the two supposed species (*M. Harryana* and *M. Lindenii*) are identical. Cultivators may distinguish them by the basis of the connate sepals generally being white in *M. Lindenii* and yellow in *M. Harryana*, although this is not invariably a reliable distinction.

— IN a correspondence which lately took place between Mr. Gladstone and Mr. Algernon Clark, the secretary of the Chamber of Agriculture, on the subject of the Colorado beetle, Mr. Clark expressed his fears that this beetle, which has made such terrible havoc amongst the Potato crop in America, would be brought over to this country. The views expressed by Mr. Clark are confirmed by Mr. Riley, the American entomologist, who, in a communication to the *New York Tribune*, expresses his belief that, if once this pest reaches the Atlantic seaboard, there will be great danger of its finding its way to Europe; for the impregnated females will live for weeks, and even months, without food, and might, in their flight, cling to the rigging of outward-bound vessels, and so be transported to these shores. As a means of preventing the evil, Mr. Riley suggests that the various agricultural and horticultural societies should disseminate, as much as possible, correct information concerning the

insect; and recommends that a small card, giving coloured figures of the beetle in its different stages, should be posted in the cabins of vessels, and other places, with a note calling upon the reader to do all in his power to exterminate the terrible scourge.

— MR. MARNOCK has sent in a plan for the new park at Sheffield. Its adoption has not, we believe, yet been actually decided upon, but in all probability it will be. It is intended to commence operations in the way of laying out the park early in May.

— WE have received from Northampton some splendid heads of Watts's Excelsior Broccoli—close, firm, and of milky whiteness. Fine as these are, however, they were surpassed in excellence by heads of this Broccoli grown at Burghley and exhibited by Mr. Gilbert at South Kensington, on Wednesday last. These were in unusually good condition.

— SOME prettily ornamented flower-pot screens were exhibited by Mr. W. H. Honey, of Regent Street, at the Royal Horticultural Society's Meeting on Wednesday last. They are made of stiff cardboard and can be readily folded up into a small compass when not in use. Attractive as this ingenious contrivance undoubtedly is, it would be still more so if it were either six or eight-sided instead of square.

— AMONG the most showy of herbaceous perennials now in flower is *Doronicum austriacum*, a fine tuft of which is flowering freely at the Exotic Nursery, Tooting. This plant, though not rare, is by no means so often met with in gardens, as, owing to its free and early blooming qualities, it deserves to be. Its large golden-yellow flowers are particularly striking, either in borders or margins of shrubberies.

— IT may be recollected that the floral decorations at Buckingham Palace, during the Shah's temporary residence there, consisted almost wholly of Roses, selected with a view to recall to his mind his own Persian "gardens of Gul in their bloom;" and so struck was his Majesty by the splendid display of these flowers which daily met his eyes, that he has, we are informed, sent an order to Mr. Wills for an extensive assortment of the same kinds to be despatched immediately to Persia.

— IN the current number of the *Revue Horticole* is a beautifully coloured plate of *Lagerstrœmia indica*, a plant long since introduced to our gardens, although now very rarely seen in cultivation. It grows freely in a warm greenhouse, bearing conical clusters of deep rosy flowers, their divisions being very crisp or wavy, and borne on slender stalks, nearly half-an-inch in length. A plant of it at Kew, 8 or 10 feet in height, flowers every season in the Palm-house, in the greatest profusion. In the neighbourhood of Paris it succeeds perfectly out of doors in summer.

— FROM the American "Monthly Report of the Department of Agriculture," we learn that in several of the States, market-gardening is very much on the increase, and that in the neighbourhood of Hudson, New Jersey, the "farmers are selling or leasing their farms to market-gardeners, who are doing a large and lucrative business." One cultivator is mentioned as having 15 acres under Strawberries alone! Another, in Monmouth county, "who has 6 acres in Wilson Blackberries, sold, last season, fruit to the value of 3,000 dollars (£600)."

— LAST autumn, a deputation of labourers on the estate of Lord Spencer waited upon his lordship at Althorp House, Northamptonshire, and requested him to allow them acre allotments for their own cultivation. Lord Spencer promised to give the application due consideration; and he has since informed the men that he has determined to try the experiment, and will commence with half-a-dozen acres next spring, to be divided among as many men, the number to be increased should the experiment prove successful. His lordship also fixed the mode of selection. At present, the labourers on his estate have Potato ground, for which they pay a low rental. An inspector is to go over these in the ensuing summer and autumn, and the occupiers of the best cultivated patches will receive the first acre allotments.

— NARCISSUS TRIANDRUS, a rare and distinct species of Daffodil, is now in flower at Mr. Parker's nursery at Tooting. The flowers of this kind are of a lemon-yellow colour, and the divisions of the perianth are turned back, in somewhat the same manner as the petals of a Cyclamen. Besides this Daffodil, there are several other showy bulbous plants at present in flower in this nursery, notably the fine *Triteleia uniflora* lilacina, which is a much more attractive plant than the common form, its flowers being of a fine blue colour throughout; *Puschkinia scilloides*, to which we directed attention a week or two ago; *Fritillaria latifolia*, a large form of the common Snake's Head; *Muscari Heldreichii*, and a goodly number of the commoner kinds of Grape Hyacinths, such as *botryoides* and its varieties, and *racemosa*, are also all just now in good condition in the same establishment.

THE FLOWER GARDEN.

HOW TO MAKE THE MOST OF SPRING FLOWERS.

In a garden at Weybridge, one of the most beautiful spots within half-an-hour's rail of London, is a picturesque mass of root-work of considerable extent, which has this spring exhibited a display of floral beauty rarely seen. The proprietor, one of our most enthusiastic lovers of horticulture has built up a root-work, so bold in its general outline, and so picturesque in its details, that the effect is quite Alpine; and, on approaching it, one expects the odours of the wild mountain Thyme to arise from beneath every footstep and fill the air with perfume. Where large masses of stone, in their natural forms, are not available, "root-work," as it is termed, may be substituted; but the wretched attempts to create a simulation of a rocky mountain-side that one often sees in suburban London, and also farther a-field, are truly distressing exhibitions to all of cultivated taste in horticultural decoration. The construction of simple

it takes nothing away from the rugged picturesqueness which is naturally sought in rock or root-gardening, as shown in the fragment selected for illustration. This kind of pseudo-Alpine gardening has many advantages; it protects small and delicate plants from the reckless spading and forking which they meet with when confided to the tender mercies of an unskilful workman in open borders. Their slender roots remain as undisturbed as in their original mountain homes, and they strew their seeds freely into the adjoining nooks and crannies, where their offspring arise around them unmolested by rash rakings and other kinds of interference. This last-named advantage is one productive of many kinds of interest; such as watching the growth of seedling plants, which have, possibly, never been seen in their earliest stages of existence by the ordinary amateur; and, also, by arousing a natural expectation that new and unusual varieties may appear among the seedlings, which is a never-failing source of pleasant speculation to true plant lovers. Another advantage of growing Alpine and other plants in this way, is the facility with which the specially favour-

Root-work embellished with Spring Flowers.

root-work is a much safer proceeding than forming a mass of miscellaneous matter in the shape of rock-work, even where not guided by taste of the best description, because, in the first place, the whole of the material employed is homogeneous in character; because, in the second place, old roots have a tendency to clothe themselves very rapidly in a raiment of Moss and Lichen of many tones of rich olive and tender grey; and because, in the third place, big root-stumps, left untrimmed, will, when piled together, however clumsily, persist in assuming more or less picturesque forms, in spite of the most inartistic arrangement.

The masses of root-work, in the Weybridge Garden, have been put together with consummate taste; they have been so arranged that the parasitic accretions of Moss and Lichen had every opportunity of developing themselves in the most favourable manner, so as to unite the different masses of root, and blend them, with beautiful tintings, into a broad general effect, which entirely conceals the fact of the mass being composed of a number of detached pieces, while

able aspect and exquisite degree of shelter may be afforded to each class of plants. The recesses or plant-niches, naturally formed by the ramifications of the greater roots, inevitably face nearly every point of the compass, affording a northward nook for tufts of shade-loving Maiden-hair Fern, an eastward-looking home for tufts of Primroses, and such plants as love the morning light but droop before the mid-day glare; and southern or western aspects for plants which delight in them. In the noble piece of root-work alluded to in this description, the plants have been grouped and classified in a most effective and interesting manner; not always as to mere colour, but invariably as to general form and character. Thus, the group represented in the annexed illustration consists entirely of Hepaticas. The pretty niche-like recess in the centre is occupied by a fine root of *H. alba*, with white stamens; and to the left, in front, is a tuft of the smaller white kind, with reddish stamens; a double variety to complete the group of whites would be desirable, but no double white is at present known. Its place might be supplied, perhaps, by a mass of

double Wood-Anemone, which flowers about the same time. To the right, in front, is a small mass of the large mauve kind, *H. Barlowii*, a very handsome plant; and to the left, in a crevice between two pieces of root, *H. angulosa* has been established. This species is very distinct; the narrow petals, of bright cærulean blue, resemble those of the Blue Mountain Anemone, and the foliage, as will be noticed, is also materially different from that of other kinds. On the extreme right, the old *H. cærulea* is seen peeping above a mossy projection, while the double-blue variety has not been added to this family group in consequence of its time of flowering occurring at a later period of the spring. On the top of the large mass of root that forms the niche below, is a fine tuft of the pale single Pink; and beyond, though not visible in the illustration, are two varieties of deeper red, one of them nearly crimson. On the extreme left, a glimpse is obtained of the beautiful double red, with its profusion of exquisitely perfect flowers, that look like a crowd of pigmy Roses—a kind which forms the glory of many a cottage border, defying the snow and hail, and bitter winds of March, from which the delicate beauty of its blossoms does not appear to receive the slightest injury. Such is the charming family group of Hepaticas, which has been established in such picturesque fashion among the artistically composed mass of root-work at Weybridge. There are many other floral beauties of the early spring displayed in a similar manner—masses of *Scilla verna*, for instance, with its pretty blooms of intense metallic blue—and, in another section of the root-work, a rich representative galaxy of the Primrose tribe. Above all, there is an exquisitely delicate group, most gracefully niched, of three distinct kinds of early Snowdrops, of which a drawing has been made expressly for THE GARDEN, and which will appear soon. These hints and descriptions regarding the formation and planting of root-work will enable those, whose tastes lead their horticultural industry in that direction, to make timely preparations for the production, next spring, of interesting groups of spring flowers as charming as those at Weybridge, which were so well worth a pilgrimage to see and admire, at the time when the drawings for these illustrations were made.

H. N. H.

DOUBLE DAISIES FOR SPRING BEDDING.

REFERRING to the notice of the arrangement of a choice spring border, consisting of eleven varieties of double Daisy, double Van Tholl Tulips, with bands of *Myosotis dissitiflora*, and mixed Crocus at back and front, described by me at page 459 in your last volume, I shall now proceed to give you my opinion as to the relative merits of the different varieties of Daisy used with a view to effectiveness in the decoration of spring borders, which I hope may be of some interest to those of your readers who take delight in pattern bedding:—1. Dickson's crimson-quilled Daisy (supplied to me by Mr. R. Dickson, of Erdington, near Birmingham), which was used for composing the whole of the ten circles, has proved itself most effective, and of first-rate quality for general bedding purposes, the colour being bright and clear, and an abundance of bloom being continuously produced on tall foot-stalks, well raised above the foliage.—2. Pink, Little Dandy, an exceedingly free-growing and pretty Daisy, making a pleasing contrast with the larger-flowering varieties, and evenly quilled.—3. Hen and Chickens Daisy. This variety, I think, unfit for this kind of work, as it is one of the latest-blooming of all the Daisies, and does not produce its flowers with any freedom till the middle of April or beginning of May; it is also too pale and undecided a colour to be effective.—4. White Queen. A variety which was strongly recommended to me by the nurseryman from whom I bought it, but which has proved utterly worthless, showing a large yellow centre.—5. Crimson King. A very good double red Daisy, free-blooming, and producing flowers of good size and substance, of a lighter shade than, and quite distinct from, the variety described as No. 1 in this list. This variety can be purchased in any quantity outside Covent Garden Market, at the moderate price of 1s. per dozen plants, and should be in every collection of Daisies.—6. Henderson's Snowball, certainly one of the best and most fully and evenly double, if not the best white, Daisy in culti-

vation, as well as by far the earliest to come into bloom. Its flowers are of a medium size, but are produced in great abundance and in regular succession, and are well raised above the foliage, which is not by any means of so vigorous or robust a habit of growth as that of most Daisies; in fact, I should say that, unless in soils and aspects that specially suited it, this fine variety might prove of a delicate and unsatisfactory constitution; but, where it thrives, it would be, indeed, hard to beat it.—7. Double red-flowered *Aucubæfolia*, an exceedingly effective and ornamental Daisy, but, unfortunately, one which the voracious and night-crawling slug has a peculiar partiality, it being the only variety touched by these animals who, during the early part of the winter, nearly ate away four out of the six plants composing this central clump, while strange to say, they did not touch the equally conspicuously variegated white-flowered variety growing alongside of it in the very next circle.—8. White-flowered *Aucubæfolia* (Flower of Spring). This fine novelty, raised by an amateur florist near Reading, and sent out for him by Messrs. Henderson, of St. John's Wood, is a great and decided acquisition to this class of plants, being of exceedingly free and vigorous habit of growth and producing its pure white-quilled flowers in great profusion which form a very pleasing contrast to the brilliant golden variegation of the foliage.—9. *Bellis roseo-tincta*, sometimes known as Pink Beauty. A most delicate and lovely variety, resembling, when the flowers are not quite fully developed, the beautiful Persian *Ranunculus*, the ground colour being bluish pink, and all the petals clearly and distinctly tipped with deep rose. Unfortunately, the flower is not quite as fully double as could be wished, many of the flowers, when fully expanded, showing a more or less hollow centre and deficiency of petals. This, I should think, might be remedied by judicious culture, selection, and hybridisation, by which means the flower might be made to come more evenly and fully double, while preserving its exquisite delicacy of tint. Still, even though unimproved, it will always commend itself to amateurs, who are not over particular, for its unique and delicate beauty.—10. *Bellis grandiflora bicolor*. A handsome parti-coloured Daisy with alternate petals, white and crimson, and of immense size and substance when it comes out really well; but, unfortunately, it is not to be relied on for early or regular blooming, for which reason I do not think I should include it in a choice border another year, but should substitute for it an exceedingly pretty deep crimson form of little Dandy recently received from a lady friend, and apparently quite distinct from its type.—11. *Bellis Ranunculiflora*. The latest blooming of all the Daisies known to me, and so unfit for use in an early spring border, such as the one now under consideration; in colour, this variety is almost exactly similar to the last-named variety, but the flowers are rather smaller in size and the habit of growth is, by no means, so vigorous. It may be useful for later work, either as an edging, or in clumps with some of the bedding Pansies or Polyanthus. I have, also, recently received a single plant of an apparently perfectly distinct and fully double white Daisy, obtained by the friend (who sent it to me for trial), I think, from Mr. George Poulton of Edmonton; if this turns out as good as it at present promises to be, I shall, in all probability, substitute it in my next pattern border for the worthless semi-double White Queen. I have also, received from Mr. R. Dean, of Ealing, a pretty light pink flowered form of *Bellis aucubæfolia*. Some of the new Victorian Daisies raised by Mr. B. W. Knight, of Battle, Sussex, are very fine indeed, though many of them, necessarily, closely resemble one another; but, as only a few of them are yet in flower, I must reserve further notice of them for the present.

Junior Carlton Club.

W. E. G.

ARRANGEMENT OF PLANTS IN VASES AND BASINS

In formal or architectural gardens, where ornamental stonework, in the shape of basins and vases, abounds, it is often possible to render them very attractive during the summer months by means of plants in pots, especially where the masonry is artistic in design. The accompanying woodcut, showing such stonework draped with elegant forms of subtropical vegetation, will serve to illustrate our meaning. We have many plants at command peculiarly well suited for this

kind of ornamentation; indeed, many of our common foliage-plants, grown in pots in the conservatory or greenhouse are greatly improved, both in health and appearance, by being grouped outside during the summer months. This is especially the case with plants that do not receive the benefit of fire-heat during winter, as the growth made outside, while they are fully exposed to shower and sunshine, is better able to withstand a low winter temperature than that made in a comparatively close and hot temperature. The best plants to use in this way are the more hardy Palms, Ferns, Solanums, Cannas, and the larger succulents, as Agaves, Aloes, Sempervivums, and Echeverias. Some of our greenhouse Yuccas, as *Y. aloifolia variegata*, and *Y. quadricolor*, are, also, all the better for being fully exposed during summer; indeed, we have seen the foliage of the latter stained with the deepest crimson after having made its growth outside, and in that condition it is one of the most effective of all hard-leaved decorative plants. In some large gardens, Agaves, Pomegranates, Oranges, Myrtles, and Portugal Laurels, are grown in pots or tubs, specially for the above-mentioned purpose, and grouped inside an ornamental stone kerb; in this way they are set off to much better advantage than when formally placed at regular distances apart along a terrace, or margin of a walk or drive. A few striking foliage plants tastefully grouped, as shown in our illustration, is far more pleasing and effective than large specimens arranged with no higher aim than that of formal symmetry. Plants about to be placed out-of-doors,

Vase and Basin furnished with Plants.

from under glass, must, however, be gradually inured to the external temperature before they are finally grouped outside in beds or vases. B.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Mossy Group.

IF, in the foregoing series of articles, which embraced the more important crustaceous Saxifrages at present in cultivation, I found some little difficulty in identifying to my satisfaction, the various species and varieties, I fear in dealing with the mossy section a far more difficult task awaits me. There is such confusion in the names, such similarity in the growth and habit of the plants, and such divergence in general appearance induced by the varying circumstances under which they may be cultivated, that I plainly foresee my task is not a light one. Engler, in dealing with this section in his "Monograph," evidently has studied the plants in their dry state as they occur in herbaria, more than in the living state; and, as a result, I must in some cases differ from him, more especially in the sequence under which I propose arranging the species. Both my grouping, as I before stated, and the order in which I arrange the species in those groups, are based on external appearances, rather than on technical distinctions, and I am not a little pleased to find that general affinities, even though these

be to a great extent purely botanical, are not unfavourable to my arrangement.

S. Burseriana of Linnæus, is a species that appears to form, as it were, the keystone of the arch connecting the crustaceous and the mossy sections together; it is a dense compact-growing plant, with tapering, almost triquetrous leaves, each terminated with a stiff mucro, the whole forming a compact mass of glaucous green, that reminds one a good deal of some of our dwarfest forms of Junipers. In verification of the statement I have made, that this forms the connecting link between the two sections, I may say that this glaucous tint, is owing to the whole surface being suffused with a crustaceous exudation not exactly uniform, it is true, but giving a thoroughly marked character to the plant. Not only in this have we a character that links it with our last section, but a still more marked one in the flowers; these are produced sparsely, each supported on an almost naked foot-stalk about 2 inches high. The flowers are large as compared with the size of the plant, of a creamy white, the pedicels being covered with a short glandular pubescence. Though this plant must be looked upon as comparatively rare in cultivation, it appears to enjoy a tolerably wide geographical range, including the Pyrenees, the Maritime and Swiss Alps, the Apennines, and extending eastwards even as far as the Mountains in Tauria.

S. juniperifolia of Adams—more generally cultivated under Haworth's name of *juniperina*—is a species that will be familiar to all Saxifrage growers. It is of rigid and compact growth, its leaves, entire, subulate, and mucronate, are arranged in dense rosettes of the brightest shining green, the whole forming a conical mass, whose beauty will arrest the attention of even a casual observer. It rarely flowers; never, indeed, have I seen, even from a large tuft, more than one or two of its dense leafy spikes developed; these rise about 1 inch above the general surface, and are surrounded with incurved glandular bracts to such an extent that the flowers individually are scarcely visible; this is of the less importance, as their beauty depends a great deal more on the large golden protruding anthers than on the petals, which are small, and, in some instances, absent altogether. This species may be readily increased by careful division and a little judicious management afterwards. It is confined to Asia Minor, where it is met with in the Caucasus, and Armenia.

S. tenella, originally described by Wulfen, is, as its name implies, a slender grower, and especially when compared with the last. Here we have creeping stems covered with linear, slenderly-mucronate, golden-green leaves, not adpressed—there we find a rigidly and densely caespitose habit of growth, dark shining green being its universal characteristic. This slender Saxifrage flowers freely on erect branching stems, and is remarkable for the well-defined ovate capsule that remains after blooming; rarely, however, does it mature perfect seeds in this country. Its flowers are pure white; this, along with its neat habit, renders it a desirable plant for the rockery, where it should have a well-drained warm sunny corner, as it is most impatient of damp, not unfrequently rotting off in a mass, if kept during winter in a frame on a cold sub-soil. It affects limestone districts in Croatia and Slavonia, and is also met with on the Alps.

S. aspera of De Candolle, is well named the rough Saxifrage; to its procumbent stems, the very appropriate title of caudiculi, meaning "little tails," is given by descriptive botanists. These stems are covered with loosely arranged linear leaves, provided with stout ciliæ along their margins, and terminated with a stiffish bristle, giving a general rough feel to the plant; added to this, its growth is irregular, and it has an habit of hybernating, if I may use the anomalous term, during the hottest part of the summer, when it presents a greyish-brown uncomfortable appearance. Rarely does it bloom, at least in cultivation, and its flowers are by no means conspicuous. Seeing, then, that its chief value consists in its being a well-defined distinct species, I need enter into no further details, beyond saying, that it enjoys a wide distribution through the whole of the South European Alps.

S. bryoides, though looked upon by Engler merely as a variety of the preceding species, is so thoroughly distinct, that I prefer retaining the old Linnæan specific name, than which nothing can be more appropriate, so exactly does the appearance of the plant represent the growth of some of the Bryums. In aspect it forms a carpet of light-coloured green, consisting of innumerable little tails, varying in length, not one-fourth the size of those in *aspera*; each tail is covered with a dense arrangement of adpressed linear leaves, terminated with soft hairs, but totally devoid of the rough bristly character of the last. Its flowers are small, generally two on a peduncle, elevated an inch or two above the general surface, somewhat yellowish in colour; not, however, produced in any abundance. It is to its general appearance, irrespective of bloom, altogether, that this plant owes its beauty. It is by no means a strong rooter, and where a few worms take possession of the pan in which it is culti-

vated, they soon give it a ragged appearance; and will, if not removed, completely loosen it from its root-hold. It has not the peculiar hybernating property of the last species, and, consequently, retains its fresh greenness through the entire summer. In its geographical distribution, bryoides is to be met with pretty generally through the whole of the central and south European Alps.

S. sedoides of Linnæus, as I stated in a previous article, was long cultivated under the name of aretioides. It appears to claim a very close relationship to the preceding species, differing chiefly in the tiny leaves being rather more rosulate than caudiculate, and in not being adpressed, but rather the reverse; its petals, also, are narrower. Lacking, therefore, as it does, the more attractive features of the former, merely chronicling it as a species will suffice.

S. Seguieri of Sprengel and **S. Androsacea** of Linnæus are so closely related, that I may consider them under one heading. As to the characters they possess in common, we have a dwarf dense growth, the tuft of radical leaves scarcely rising half-an-inch above the surface of the soil; the tail-like character, which we found in several of the foregoing species is totally absent here; the flowers are small, elevated on foot-stalks about 2 to 3 inches high, pure white, those of the latter species bearing a very marked resemblance to the genus *Androsacea*, from which it derives its name, owing to a greater rotundity of corolla, and also to its petals being emarginate, or slightly notched inwards at the points. The most important distinctive character consists in the leaves of the former being lanceolate and entire; those of the latter have generally three, or even sometimes five, teeth towards the apex; usually speaking, however, the central one is so large, as compared with the side ones, that they are apt to be lost sight of; it, however, indicates the first change into the notched or divided-leaved section of the mossy group. It is very seldom one sees either species happy and thriving in cultivation. My success in either case has not been satisfactory. Drought they cannot bear, and to shade they appear to have an equal objection. I fancy those double-walled pots I alluded to when describing the garden at Benthall Hall, and which are now to be purchased in the trade, will be admirably suited for such plants as these. Possibly some of the want of success may be attributable to a too great greed for division when the plants are first introduced, sacrificing health and vigour in the whole for the gain of a few plants. Geographically speaking, both plants have a pretty wide distribution. *Androsacea* extends through the mountain districts of Europe as far as Lake Baikal, in Asia; *Seguieri* is generally met with at very great altitudes, and, no doubt, has a tender affection for the pure cool draught at the snow-fountain.

S. Stelleriana of Merck, is looked upon by Engler as a variety of *S. bronchialis* of Linnæus, to which he applies the name *cherlerioides*; and, unquestionably, the plant that we have long cultivated under the above specific title is identical, so far as I can make out, with this variety, albeit, Engler's name is not a very happy one; but, seeing that I have never met with the true specific type in cultivation, I am disposed to retain it as a species, at least till such time as we get the true *bronchialis*; it is a creeping plant, its procumbent caudicles being well furnished with somewhat fleshy, small, concave leaves, beautifully ciliated along their margins, and broadly lanceolate and spathulate in shape; its flowers are supported on short glandular pedicels, are of a greenish-white, and are produced in very limited numbers. Its home is in Siberia, where it has an extensive range as far as Behring's Straits, occurring also on the American Continent at Unalaschka, and along the range of the Rocky Mountains for a considerable distance.

S. tricuspidata of Retzius, has long been in cultivation, and is one of the species belonging to this section that carries not only its specific character, but its very name, on the face of every leaf; it is much closer allied to the last species than would at first sight appear—larger in growth and foliage, with the leaves less densely arranged on the procumbent branches; during the summer, the leaf margins are tinted with a beautiful chocolate-brown, which colour covers the entire plant during winter. Its specific character is derived from the leaves; these are fleshy, distinctly divided into three pointed mucronate lobes at the apex, the centre or terminal one being much the longest, each margined with a hard cartilaginous mass. Its period of blooming has varied much with me—sometimes in April, but more generally in August or September. The flowers are four or five in number, supported on a slender pedicel, and of a pale yellow or straw colour, which contrasts very prettily with the small chocolate lobes of the calyx. It is a native of North America, where it extends from Kotzebue Sound to Greenland, and far into the Arctic regions. Sometimes a slight variation occurs whenever the two side teeth are suppressed, or merely represented by two stiff bristling hairs; and to this form I have seen the name *cuspidata* applied; but, as I find this variation occurring frequently on the *S.*

tricuspidata plant, and possessing no constancy of character, it would clearly be wrong to give it the status even of a variety. Added to this, there is a perfectly distinct species not at present, I believe, in cultivation, to which the name *cuspidata* is given.

S. spathulata of Desfontaines, as a species ought properly to take its position between the foregoing, possessing, as it does, entire leaves devoid of any lobes or notches whatever. The plant consists of a number of procumbent stems, well covered with foliage, sometimes arranged in rather dense small rosettes. The leaves are entire, lanceolate, concave on the upper surface, and edged with delicate spider web-like ciliæ. Its flowers, which are produced more freely than in either of the foregoing species, are whitish, growing in threes or fours upon naked peduncles some 4 inches long. It is a north African species, and is met with as far inland as Mount Atlas where it grows at a considerable altitude. In spite of its southern origin, it is found to be perfectly hardy in cultivation, if planted in a well-drained and thoroughly exposed corner of the rockery.

A Twofold Chord of Spring Beauty.—The highest beauty is mostly composed of the simplest elements. By putting too many colours into our pictures we spoil them; we produce distraction where we ought to find repose. We want embroidery aglow with beauty for the early spring, or a double shading of two colours that shall produce a striking contrast and yet yield repose. You have only to dip your brush—trowel, I mean—into two large beds of golden Thyme and the early Forget-me-not (*Myosotis dissitiflora*), plant them anyhow, anyhow, near each other in masses, patterns, beds, lines, straight or curved, and they are beautiful; the eye never wearies of them. In bright colours and style of growth so different yet so in unison, they form one of the most effective of all combinations. Another twofold chord of beauty is formed of the white Arabis and the same Forget-me-not; the one seems so much whiter and the other so much bluer by contrast. Primroses, again, are fine against the Forget-me-not; in fact, I know no yellow, orange, or white, that is not improved by close proximity to this lovely Forget-me-not. It should not, however, be put near to Aubrietias, nor blue-violet, nor violet, nor purple flowers of any kind. For carpeting for golden Daffodils it is superb; the latter, ruffled by the wind, seem, indeed, dangling in an azure sea. But, enough; else my friends will declare that I have Forget-me-not on the brain. It is, certainly, the pet of all the flowers of the spring, and in beauty far exceeds them all.—D. T. F.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Pasque Flower (*Anemone Pulsatilla*).—This beautiful old plant ought to have a place in every garden, however small, as it requires no care and but little room. I have a fine plant of it, which has not been disturbed for years, and which is a most beautiful object every Easter. This season it has produced from fifty to sixty of its beautiful silky blossoms.—J. WHITTAKER, Morley, Derby.

Varieties of Primroses now in Flower in the York Nurseries.—The following, many of which are very beautiful, are now in flower here, viz.:—*P. amœna* (one of the earliest, commencing early in March), *purpurea denticulata*, *pulcherrima* (Backh.), *integrifolia*, *Candolleana*, *Dinyana*, *villosa*, *viscosa*, *nivalis*, *marginata*, *glaucescens*, *Wulfeniana*, *tyrolensis*, *ciliata minima*, *auriculata*, *farinosa*, *farinosa v. acaulis*, *commutata*, *Clusiana*, *cenensis*.—RICHARD POTTER.

The Dwarf Flag (*Iris pumila*).—This pretty little Iris is now being brought to Covent Garden Market in quantities, and it well deserves attention. We have grown it in a warm peaty soil, with a good sprinkling of sand, and when so treated, it thrives well and flowers profusely. Its leaves are like those of the common German Iris, but they seldom exceed 2 or 3 inches in length and the flowers, which are violet-purple, are borne on short stems not above 3 inches in height. It is a native of the south of Europe, and should find a place in every warm sandy border where it will bloom freely about this time.—J. W. T.

Wallflowers.—Nothing is better than the single yellow Wallflower for naturalising on warm sandy borders, rock-work, or natural rocks, or old walls. Once established it reproduces itself freely from seed, and never fails to make a brilliant show in early spring. Many old ruins of historical interest throughout the country are covered with it, but nowhere is it seen to more advantage than on the Sandstone bluff, just below Nottingham Castle, where its golden flowers show to great advantage while the purple Vernal Crocus is freely dotted over the fresh grassy meadows at the foot of the "Castle" rock. Nice little plants of this Wallflower are now being sold in Covent Garden Market at 1d. or 2d. apiece.—Q.

Daffodils.—We have no fewer than eight single and double forms of the incomparable Daffodil now before us from Mr. Barr's grounds at Tooting; and they are all of such a clear and beautiful yellow or creamy white, with the orange segment of the cup scattered among their perianth divisions, that we are surprised that these fine hardy bulbous plants have been so much neglected by modern cultivators, especially after what has been done by Parkinson, Haworth, Ellacombe, and others. Mr. Barr's collection is perhaps the richest in species and forms of any in Europe, the plants being well-grown and robust, instead of poor starved examples, such as are too often found at the present time in gardens in which they happen to be grown.—B. H.

THE INDOOR GARDEN.

ORNAMENTAL CYCADS.

SINCE the rage for Ferns has, to some extent, subsided in favour of Dracænas, Crotons, and Palms, the more ornamental Cycads have been brought to the front, and, as evergreen decorative plants, they well deserve such prominence, many of them being particularly interesting. It has been said that they combine the fresh green aspect of our finest Ferns with the graceful habit and permanence of the Palm, and possessing distinct and striking characteristics peculiarly their own, and this, in some cases, is correct, but in others their colouring and general contour is wholly different from both. Although, for the most part, natives of tropical countries, they nearly all grow freely in this country, in a warm greenhouse or conservatory, under precisely the same treatment as is desirable for our more hardy Palms. Their propagation is, for the most part, difficult, but this is the less to be regretted, as old specimens are as easily imported as Tree-Fern trunks, and some now produce offsets, or root-suckers, by which the plant can be readily reproduced. They will be found to grow best in a well-drained compost of fibrous-loam broken up into lumps

about the size of a pigeon's egg, and they will require a copious supply of moisture during the warmest portion of the year. The plant, of which the accompanying is an illustration, is one of the best in its class for conservatory decoration, or even for sub-tropical gardening during the summer months. It is not a quick grower, but very permanent in its character, as are all the other species; hence it is advisable to be careful not to injure any of their foliage; inasmuch, as any bruises or broken parts remain blemishes for years. Other species in this group are also very effective when well grown, and none more so than the blue-foliaged *E. horridus*, a stout dense-growing form, with pinose foliage, and one of the most striking of all foliage-plants for conservatory decoration. *E.*

lafferi—or, as it is popularly called, Hottentot Bread—is another noble plant, forming, as it does, a fine trunk, surmounted by deep green leathery foliage, which droops or arches gracefully on all sides. There are some good specimens of this in the Palm-house at Kew, and it deserves a place in every collection of warm conservatory plants. Some of the Australian *Macrozamia*s are likewise striking in habit, and well worth more general cultivation than they at present receive. *M. corallipes* has a short rounded trunk, and a gracefully-curved diverging plume of deep glossy foliage. Of this plant there are one or two forms, the most distinct being *M. corallipes gyrata*, which has its offsets spreading out from the glossy rachis in all directions instead of lying flat, as in the normal type. *M. elegantissima*, *M. spiralis*, and others, are all well worth a place where variety is desired in plant-houses, inasmuch as the whole group of Cycads are as invaluable and as deserving of general culture as are the Palms themselves, although they are more limited in number. Many come from the Cape district and Natal, or Southern Africa, where they form distinctive features of the vegetation. They should be carefully watered during winter, as any injury from excess of moisture will not be evident for weeks after the mischief is done.

B.

PLANTS FOR BASKETS.

By GEORGE WESTLAND, Witley Court.

THERE are many of our most beautiful plants that are seen to best advantage when grown in hanging-baskets; naturally, such as are of a pendent habit of growth are most effective when so suspended that their gracefulness and beauty of inflorescence are fully discernible. Largely as these basket plants are now employed, there is still ample room for extension, and by breaking up many of the stiff, lumpish, uninteresting combinations which we not unfrequently meet with in plant houses, with judiciously disposed groups of tastefully-filled baskets, we would render them much more effective and enjoyable than they now are. There is scarcely a class of plants which does not present suitable material for this purpose, both as regards foliage and flowers; we have Orchids in abundance, and the quaint and singular *Nepenthes*, which have long been extensively cultivated in baskets; but, however interesting and desirable these may be, with few exceptions, they are too tender to bear exposure in a show-house. For the embellishment of the conservatory during the summer months, the *Achimenes* recommends itself, from its free-blooming properties and admirable adaptability for basket-work, as one of

the most effective plants we can employ. The hardiest sorts should be chosen for this purpose, as many of the delicate kinds stand exposure badly; when the plants are well-established in the baskets, they should be hung up in the position in which they are to bloom, so that they may become inured to it previously to flowering. This is important to ensure perfect success, if the position is at all exposed; next to the *Achimenes*, I would recommend *Petunias*; they are most gorgeous subjects when freely-cultivated in good-sized baskets, which will contain from ten to twelve plants around the rim, with a *Geranium* or a *Begonia* in the centre. They may be propagated from named sorts, or (what I prefer) from seed of the best hybrids, which produce a charming variety of colours with

a large proportion of striped sorts. These will bloom for several months in the greatest profusion, and are not excelled, for effectiveness, by any other class of plants I have seen tried. I have grown them so as to hang down 8 feet or more below the baskets, and they stand exposure well. Again, there are the varieties of the Ivy-leaved *Pelargonium*, all most appropriate subjects for a cold house, and forming charming baskets when thoroughly established. A single plant of some striking *Geranium* as a centre, and a mixed or simple coloured fringe of the Ivy-leaved round it, will last for months in good condition; I have grown these so as to hang down 10 feet from the baskets. The old plants trained and re-planted bloom best.

Tropæolums are likewise most desirable subjects for basket-work, as is also the charming *Convolvulus mauritanicus*, and the dazzling hues of the *Clematis* are most vividly displayed when drooping in this manner. Amongst evergreen drooping plants, nothing surpasses the variegated *Vinca major elegantissima*, its gracefully streaming spray and reflexed leaves being specially beautiful in such a position. We plant the centres with Scarlet *Geraniums*, and re-plant the *Vinca* annually during the early spring months, cutting away the previous

Encephalartus Altensteinii.

year's growth; and so rapid is their growth that, in three months' time, the new plants will have reached the ground, which is 18 feet from the baskets. For suspending in dark corridors and situations where it is difficult to get tender subjects to succeed, this is the most satisfactory plant I know. There are many charmingly pretty plants requiring a stove temperature, such as *Æschynanthus*, *Hoya Bella*, *Coccocypselum discolor*, *Torenia*, *Panicum*, *Pothos*, *Argyreia*, and *Gymnostachyums*, which are specially valuable as basket-plants, and which display their natural developments of character to the best possible advantage when so grown, besides presenting very graceful and pleasing features.

We have still another very large and popular class of plants in the Ferns, which are most adaptable to basket-culture from their habit of growth, and the graceful elegance of their fronds. Most of the *Davallias*, with creeping rhizomes, *Drynaria*, *Nipholobolus*, *Lygodium*, *Nephrolepis*, *Adiantums*, *Asplenium flabellifolium*, the bold and graceful *Goniophlebium sub-auriculatum*, and the quaint and picturesque aspect of the *Platynerium*, which adapts itself most admirably to this form of culture, and contrasts so forcibly with the fragile elegance of the other kinds, are all suitable for baskets. These may be grown singly, covering the Moss with *Lycopods*, or they may be grouped. When the baskets are small, care should be taken that they are not over-crowded, as they grow so freely.

A great point in the cultivation of plants in baskets during the summer months is, to give them an abundant supply of water. If the foliage is allowed to become sickly through any lack of moisture, the thorough effectiveness of the plants is very much marred. The above are but mere indications of the many subjects that are suited for baskets—a mode of culture which has much to recommend it.

POINSETTIA PULCHERRIMA.

As a winter decorative plant this is one of the most valuable plants in cultivation, and in every garden, where winter-flowering plants are used, its cultivation should be made a speciality. True, the habit of the plant is not of the most attractive character, but that can be considerably modified with proper management; and the brilliancy of the colouring of its rich crimson bracts, together with their great size and lasting power, quite counterbalance every defect. Generally, the culture of this excellent plant is but imperfectly understood, and, considering the torture it sometimes has to undergo, the great wonder is that it has stood its ground so well as it has done. How often do we see it crowded in among miscellaneous stove-plants in positions where only the few leaves at the top of the stem can see the light or feel the fresh air playing about them, instead of their being kept cool and airy during the summer months, so that the wood may be ripened and consolidated. In describing the form of culture now generally adopted by good cultivators, and which has proved most successful in its results, we will suppose a beginning being made with young plants from cuttings. These may be taken about the month of March, when the wood has been well rested after flowering. In cutting down the old plants, the best of the wood should be saved for propagating purposes. When we say the best, it must by no means follow that the strongest is meant, as that is sometimes sadly deficient in some of the most important points; but that which is moderately strong is generally to be preferred, as it will be found firmest and most thoroughly ripened. It should then be cut up into short pieces in a similar manner to that in which Vine eyes are prepared, that is, by cutting off the wood within $\frac{3}{4}$ inch of the eye on each side of it; or, they may be cut off under another joint, as some prefer; but this is not essential, as they will be found to root easily either way. The pieces may then be planted upright in pots or pans, keeping the growing eyes level with the surface; and, if plunged in a bottom-heat of 70° or 75° they will soon root freely. A mixture of rich fibry loam, with a little sand, leaf-mould, and well-rotted manure, may then be prepared for potting them off; and if this be done carefully, using 3-inch pots, and returning them to the bottom-heat, they will start away at once, and will soon be well-established. As soon as the pots are well filled with roots, they may be removed to a cooler situation; and, after being hardened off a little, the plants may be again shifted into 6 or 7-inch pots this time, which will be large enough for the first season; they may then be placed in a cold frame, as close to the glass as possible, and will require nothing more till the end of summer, when they may be returned to a moderately warm house, and may be brought in quickly, or gradually, as may be wished. Abundance of moisture must be supplied during all

the growing season, and the foliage should be frequently syringed, keep down red spider and promote healthy growth. Liquid-manure may be applied freely as the blooming season draws near, which will assist in increasing the size of the bracts, rendering them more persistent. As soon as the coloured leaves are well-developed, they may be removed to a cool conservatory or greenhouse, where they will stand for a long time, and will be very effectual in enlivening the dull foliage of the plants around them. When done flowering, they may be gradually hardened off, and water may be partly withheld, they sink to rest, and in due time the process may be begun again. The treatment of old plants is similar to that already described for cuttings. When they have been cut back, they may be placed in slight bottom-heat until they break into growth, when they may be shaken out of the pots, and as much of the old soil removed as can be detached without injury to the roots. They may then be re-potted into the same, or rather less-sized pots, and be returned to their places until they get well started again, when they may be grown along with the young plants as here recommended. The usual way is to grow only one plant in a pot, and by this means the finest heads are obtained; but, where a mass is wanted, larger pots may be used, and two or more plants grown together to suit the circumstances. In the case of old plants which have become too leggy and bare to be presentable, they may be economised by taking the tops off in August and striking them as cuttings. They may be cut about 6 or 8 inches long, and inserted in the centre of small pots singly, and if plunged in brisk bottom-heat and kept shaded and moist for a few days, they will quickly root, and may be transferred to 6-inch pots, and will make nice dwarf plants for room or table decoration, as they will flower nearly as well as if they had been allowed to remain on the parent plant. In addition to the crimson variety, which is the one usually cultivated, there is a white variety which is seldom met with, probably on account of the white not being decided enough to render it a desirable addition.—J. L.

Do Leaves Absorb Moisture?—At the opening of the Gardeners' Institute, at Darlington, the Rev. C. Peach addressed the meeting, and alluded to leaves absorbing moisture. He said, "This is a great question now with some of our French horticulturists who are of opinion that leaves do not absorb moisture." He further stated, "A very common occurrence after a very bright day in spring, on entering a propagating-house, say a house of young Roses or Verbenas, is to find them flagging. We at once start to syringe them, and thus are actually doing harm instead of good. Have leaves, therefore, the power of absorbing moisture or not?" Y. B., *Darlington*. [We have no definite proof that leaves absorb moisture, although, as is well known, a humid atmosphere is essential to the welfare of growing plants. No doubt syringing does harm under the circumstances just related, unless shading is applied at the same time. When we shade growing plants and cuttings, and keep them constantly moist, it is not so much with the idea that they will absorb moisture as that humidity and shade combined lessen, to a very great extent, the transpiration which would otherwise take place from the leaves, thus causing them to droop or "flag." Every propagator is aware that moisture alone will prevent cuttings from flagging; they are, therefore, very careful to keep their cases well shaded from bright sunshine.—Ed.]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Clematis indivisa lobata.—In addition to what your correspondent says (see p. 260), in reference to this plant, I would recommend it on account of its producing its flowers for about two months in succession. In cutting the blooms, those should be taken which are not fully developed, as they keep much longer than such as are wholly open. Plants only a few feet high bloom quite profusely.—F.

Phalanopsis Parishii.—This pretty little plant is now flowering in Messrs. Veitch's Orchid-houses, at Chelsea. It is one of the smallest of all Orchids, having glaucous leaves only about an inch in length, and bearing two to seven pearly-white flowers on a spike about the same length. The lip is heart-shaped, and deep purple, with a few white hairs at the base. Although very small, it deserves cultivation, its flowers being pretty when closely inspected, and quite unlike those of any other member of this well-known group.—B.

Fuchsias.—What varieties of Fuchsia are best adapted for standards and pillars in a cool conservatory?—T. BARNES, *Kew*. [The old Fuchsia corallina does remarkably well in the gardens at Chiswick House, trained up the rafters like Vines. Souvenir de Chiswick and Venus de Medici, are also two other of our favourites that are well suited for the purposes you name. Plant them out in rich well-manured compost, and train them up in the form of a single stem, removing all laterals until they are as high as required. After they have finished blooming in autumn, prune the laterals close in, just as is done in the case of Grape Vines, and start the plants afresh in the spring, by applying a little heat and syringing them with tepid water; so treated, they will bloom profusely, and are among the most beautiful of all cool conservatory plants. We saw some at Hatfield last autumn, and magnificent they were, having been in bloom for three or four months. When so grown, cut branches of some of them are very useful for drawing-room vases.—Ed.]

THE GARDEN IN THE HOUSE.

PLANT-CASES AND AQUARIA COMBINED.

THERE are several drawbacks to the more general culture of tender Ferns and ornamental-foliaged plants in ordinary apartments. In the first place the temperature is very unequal, and the plants, if fully exposed, suffer from the aridity caused by open fires and gas. In order to regulate the temperature as much as possible, and, at the same time, protect the plants from dryness and other injurious influences, we have recourse to Wardian cases, and these, to a great extent, enable us to make the most of tender plants as embellishments for the sitting-room or boudoir. A plant-case, when of graceful form and well made, is a most excellent invention, and one that ought to be introduced into every home of taste, where fresh plants and delicately-tinted flowers are admired, and where there are no means of cultivating them except in windows. A badly constructed case is a great nuisance, and only proves a source of annoyance to its possessor. One of the best plant-cases we have ever seen was made by an industrious artisan for the amusement of a sickly daughter. This was of wood, with a flat zinc pan inside to contain the soil in which the plants were grown, while a large bell-glass in the centre contained leeches, water beetles, lizards, gold fish, and other aquatic animals, a handful of coarse sand at the bottom serving

Plant-case and Aquarium combined.

for the growth of a few pieces of *Anacharis*, *Vallisneria*, and other small water plants. It was glazed with 21-oz. glass, and neatly painted both inside and out. The vegetation around the bell-glass consisted, for the most part, of small-growing Ferns, as *Asplenium flabellifolium*, *A. Trichomanes*, and *Scolopendrium vulgare*, all of which grew vigorously, while the whole surface of the soil, being carpeted with fresh green *Selaginella*, had a most pleasing and refreshing appearance. We have recently seen some very pretty designs for aquaria and Fern-cases combined, one of the best being that of which the accompanying is an illustration. It is novel in point of construction, varying from most others which we have seen in having the aquarium between, instead of below, the compartment for ordinary vegetation. It is one of the many elegant introductions of Messrs. Bromwich, of South Belgravia. We recently saw one of these cases tastefully planted with Ferns, Palms, and other foliage plants, Mosses, and *Selaginella*, and the whole had a bright and cheerful effect, being enlivened by the sparkling water and gold fish, the warm hues of which contrast so well with fresh vegetation.

STANDS OF HARDY FERNS.

FOR the decoration of sitting-rooms in large towns, these are particularly well-suited, and yet it is seldom they are employed for that purpose, because I suppose those who have not tried their effect, or seen them, do not care to experimentalise in the matter; those, however, who will try their effect will not be disappointed. Hardy Ferns stand every change in the atmosphere, and look quite as effective as

the more tender varieties. I first saw an arrangement of this kind in an apartment in a large town in which it continued in good condition for two years. The stand had been formerly a hanging-basket, but, in order to convert it into a stand, the chains by which it had been wont to hang had been taken off, and a wire-worker supplied it with four feet, or supports, which raised it about eight or ten inches from the table on which it stood. The basket was lined with Moss in a growing state, at least it had a bright and fresh appearance; inside of this was a layer of broken crocks. The rest of the basket was then filled with a mixture of peat, loam, and silver-sand, in which the Fern roots were planted. The basket was about a foot across; planted in the centre was a nice specimen of the Hart's-tongue Fern (*Scolopendrium vulgare*), and round it were mixed varieties, such as *Asplenium Trichomanes*, *Asplenium marinum*, *Polypodium vulgare*, and several other small plants of *Lastrea Filix-mas*, and similar Ferns. The surface of the soil was covered over with fresh-looking wood Moss. Another stand of this kind, only on a much larger scale, was as follows:—The stand was at least 2 feet across, and each plant in it was growing in a separate pot; but this was concealed by the Moss with which the pots were packed. In addition to the Ferns, this stand was furnished with several plants of plain and variegated Ivy, which were so placed that they drooped round the edge, and had a very charming effect. In the centre was a large sized plant of *Lastrea Filix-mas*, and round it were grouped several other good-sized specimens of British Ferns. In winter, the plants were watered about twice a week, the pots being lifted out of the stand and watered in another room. The Moss, also, was damped, which tended to keep the plants fresh.

A. HASSARD.

Upper Norwood.

AUCUBAS FOR INDOOR DECORATION.

AMONG hardy shrubs, there are but few that rival Aucubas in their brightness or aspect, or in adaptability for town planting. Even as pot plants for windows or balconies they are invaluable, more especially during the winter, when any scrap of fresh vegetation is welcome. Aucubas will grow in any ordinary garden soil, and are easily propagated, either by means of seeds, cuttings, or layers; or, if no facilities for their reproduction exist, nice bushy little plants may be bought for a trifling sum either at the nurseries or in Covent Garden. Just at this season they commence their growth, and will shortly flower, so that if to the other ornamental properties are to be added rich scarlet berries, male plants or flowers must be procured at once. No one who has seen a nice bushy Aucuba, bearing berries, would ever care to see it without them at the proper season; and, as the mechanical part of fertilisation consists in merely conveying the powdery pollen from the male plants to the little green stigmas of the female flowers, fruit is easily obtained. Fertilisation is best effected with a moist camel's-hair pencil during bright sunny weather. If the pencil or brush is first moistened in honey so much the better. One male plant, grown in a pot, will produce pollen sufficient for a great many female plants. It is best to assist the process of fertilisation in the way just described, but, if several female plants are set in a cool airy house, and a male plant placed among them, they often produce heavy crops of fruit without any extraneous aid. If only a few plants are grown, pollen or male blooms may be obtained from some nurserymen for a trifle. If neatly wrapped in tinfoil it will preserve its fecundating powers for several weeks, if kept free from damp. Aucubas will last for several consecutive months, and will require no attention beyond periodical waterings and occasional syringings with clean water. R.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Aaron's Beard Saxifrage.—What is the name of the enclosed plant? It grows well in my window. It never blooms, but the leaves are pretty.—J. S. [What you have sent is a piece of what is commonly called "the Sailor plant," or "Aaron's Beard" (*Saxifraga sarmentosa*). It is a first-rate plant for a hanging-basket or bracket-pot. It is viviparous, and is very readily propagated by layering the runners in the same way as Strawberries are layered. When well-grown it forms a pretty object in a room window. You are wrong, however, in supposing that it never blooms. It bears white flowers on a spike about a foot high, but it is well worth growing on account of its silvery bloomed leaves alone, even if no flowers made their appearance.—F. W. B.]

The Common Myrtle.—This, as most of us know, makes a capital window plant grown in a small pot, and kept fresh and clean by means of frequent sprinklings. One of the best restorers for all pot-plants is to set them outside when it rains. This is far better, and does them much more good than sprinkling or sponging them indoors. My plants of Myrtle have grown in a north window for these last ten years, and have repeatedly been frosted, but they suffered no harm on that account, and they are now a fine pair, 2 feet high, and nearly as much through, notwithstanding their being repeatedly robbed of cuttings and branches for friends who admire them. I have a plant in front of the house planted out in the border, but this is generally cut down every winter, and makes but little progress. This season, however, it has escaped, and I hope that it will get strength enough now to resist a severe frost.—A. H.

A HOLIDAY TOUR.

By THE EDITOR.

ROME.

SPEAKING of gardens to a French amateur, long resident in Rome, I was not encouraged to hear that there was "nothing to be seen. Horticulture exists not at Rome." Well, it is not quite so bad as that; but there was some ground for the opinion. In Rome, the home of art, Nature is almost a stranger; for ages the world was drained of much of its wealth for her art and glory; but a very small mite has been devoted to cultivate the study of natural history. If the city of the New Methusaleh, in the western wilds of America (an important and rising capital, consisting of some sixty-three houses, and several spacious and airy streets without any) makes up its mind to have a park, it will begin by making one far better than anything of the kind here. Dublin, Nantes, and Brussels have each sent their Peter's pence to Rome, and have never been much enriched by creed or conqueror; but the least of these cities has a botanic garden, to which that of Rome is insignificant; yet the climate is a glorious one for vegetation—the Palm and the Rock-Rose, the Prickly Pear and the Violet, the Olive and the Ivy all thriving together. Ah! if they had only been satisfied with, say a quarter of an acre of pictures less, and given the difference to showing what the soil and climate were capable of producing, it might easily have been made a fairer land than it now is. For, in Italy, it has been proved again and again that, when men are driven from their fields by war, or when cultivation is, from any cause, put a stop to in a given district, malaria begins to spread its fatal breath over the land, which soon becomes uninhabitable. But such things mattered little to those whose great aim was to carve quarries of marble into god-like shapes, or cover miles of wall with wearying repetitions of the same subjects, or raise pile after pile into the sky, spinning away the souls of all the greatest at unproductive work. Yes, and worse; for what is the good of it all, if it does not make men better and happier? Means that would suffice to improve a whole district, are devoted to paintings in a single church. Frequently may be seen a fine stretch of level land without a habitation on it. However, the people, or what remains of them, can all crowd up to the closely-built town on the top of the hill, where there are innumerable works of art, and where the streets are very narrow, and by no means sweet. Sometimes, as in Naples, the dwellers in these close streets, are the meanest-looking wretches one could find in Europe. Although in one of the fairest lands under the sun, they benefit nothing by it, between these close rows of six-storied houses. But what did it matter about the real men and women, when there were whole skyfuls of painted angels? And it is not only on the town dwellers the result may be judged of. Look at these bent figures in the fields; for ages the hand of the taxgatherer has left them nothing but black bread and sour wine, and long days of unbroken labour; and this poor fare and thankless toil, not always for any noble or necessary work, but too frequently for the mere gratification of vanity, in building uninhabitable palaces, and costly gardens of stone. Art has its place, and a most important one, but it is on all counts a mistake to act invariably as if the imitation were better than the life. Let us leave these exhaustible galleries and domes for the open air. Look at this picture of the Pincio Gardens, the most important public garden in Rome. It is a varied and pleasing composition; but that is mainly owing to the predominance of trees that occur everywhere here, the Stone Pine and the Cypress—the two most picturesque Italian trees. They almost seem made to contrast with each other—the Cypress tapering to a point like a Willow-wand—the Pine spreading out its head like an umbrella. Till recently, little more had been done to assist the effect of these trees; but now a portion of the ground is tastefully planted, and shows Palms and Araucarias and Conifers, all in good condition. This portion, however, is a mere patch in a somewhat formal garden, occupying a fine site, and disagreeably spotted with new white busts. These busts (which surely would be better in some of the public buildings) will by-and-bye assume a more sober hue; a random Lichen will spread

over them, and cover them with a mouse-coloured tint, so that the merely spotty will become the spotty-grotesque. A single statue, well placed in a green garden, is sometimes a pleasing feature, as in Professor Owen's garden at Sheen; but, dot statues at regular intervals along the front of a shrubbery, as is frequently done here, and a most objectionable and inartistic effect is at once produced; whether the statues are good or bad, the distant effect is the same. The plants give what character they possess to the small public gardens. Here are, in addition to the Date Palms and the Fir Palms, the American Aloe, the Prickly Pear, the Aloe-leaved Yucca (both green and striped forms), the Great Peruvian Cactus, which grows finely in warm spots, and particularly the Acanthuses and Ferulas, with their fine fresh foliage. A beautiful object on the Pincio is a tall Date, with its stem clad with a glossy mantle of Irish Ivy. This union shows well the peculiarly favourable conditions which exist here for every kind of planting, and are suggestive of how much may be done when the country is awakened to the importance of such matters. It is in the gardens of the wealthy Romans that one finds most interest, but even that is of a limited kind. Of a good many famous gardens seen in Rome, that of the Villa Pamphili is the most remarkable. This is mainly distinguished from English gardens of the geometrical order by an abundance of plants in huge pots and vases, and by vegetation, to some extent, subduing the formal lines, where it descends to box and coloured gravel patterns; it is very poor indeed, as all such gardens must ever be. The scroll-work, however, is not so offensive here as in other gardens, and the French plan of clipping or mowing the trees into walls is not resorted to as it is at the Medici, and not a few other Italian gardens. On the walls, and by the steps, and everywhere one turns, there are very large earthenware pots, of bold and not ungraceful designs, filled with Orange trees, Agaves, Yuccas, Prickly Pears (*Opuntia*), and many other plants. The most strikingly effective of these is, decidedly, the Prickly Pear, which, with its great arms bearing broad shield-like leaves, is utterly distinct, in aspect, from any other vase plant. The only improvement suggested by this garden is in the matter of these vases and pots. Imagine pots of common earthenware, 5 feet in diameter, and with a rim 3 inches thick, the surface embellished with a wreath or other design; pots of this kind, small and large, are very often seen here, and those of good design are quite cheap; they are simply our common red pots cast in graceful forms, and deserve to be used largely in England. The custom, seen occasionally here, of wreathing the *Wistaria* and other plants round the stems of large trees is a tasteful one. In the Pamphili Gardens there are tall pillars formed by *Wistaria* alone, and which must be effective; *Camellias* are grown very extensively, and, being now in full bloom are very attractive; although thriving in the open air it is found desirable to protect them with screens formed of the Canes of the great Reed (*Arundo Donax*) which prevent the flowers suffering by violent changes of weather. The screen is easily fixed when the border of *Camellias* is against a wall. It is interesting to notice that the Neapolitan Violet, which is very much grown here, is cultivated in frames, just as in England. It is used so largely that in one garden I saw over a hundred feet long of frames devoted to it alone. The sweet Violet abounds everywhere, and is one of the many plants that may be noticed growing on the stems of the Date Palm—rooted among the decaying fibre and on the stumps of the old leaf-stalks. At Rome the fruit is not sufficiently developed to become edible, but the seeds, notwithstanding, vegetate and produce good plants. The most strikingly graceful tree in Roman gardens is a Sumach (*Rhus viminalis*), which reminds one slightly of a Weeping Willow, and attains a height of nearly 20 feet. Even admirers of the well-known Japan Privet would be surprised to see it used as a street tree, with a clean bole, 6 inches in diameter—a handsome round evergreen head, and leaves somewhat like an Orange, but more leathery. It does not, like tall trees, require continual cutting-in when used in small streets, and is the best evergreen I have ever seen used for street planting, the head assuming the very shape and size that is required, and the flowers having much beauty. The Creeping Fig, everywhere seen in our hot-

THE PINCIO GARDENS, ROME.

houses, grows against a wall in the Botanic Garden here, with leaves 4 inches long, and fruit bigger than the common Fig; while beside it, on the same wall, and growing from the same root, are small shoots with delicate little leaves and wiry stems. It seems curiously influenced by conditions. I once saw a plant of it, in the open air, on a wall at Woodstock, intermediate in size between the small growth in our houses and the Tree-Ivy-like growth here, all the leaves being of a fine bronzy colour.

The garland-forest, which the gray walls wear,
Like Laurels on the bald first Cæsar's head.

If Popes and Emperors were so busy carving and painting that they had no time for planting trees, Nature was as busy, as usual, with her handiwork. As soon as the mighty aqueduct or colossal wall was reared, she sent certain emissaries—some from the Apennines and some from the fields and hills around—in the shape of tiny seeds, which soon planted her flags on those haughty walls; and when the Colosseum had lost its glory, and both arena and mountains of stairs were desolate of men, the Anemones, and other flowers of spring, came and touched the ruins with hues of life, till the place almost looked like a patch of flowery mountain. And Sylvanus sent his children, too, who planted—

A grove which springs through levelled battlements;
And twines its roots with the imperial hearths.

And on the colossal walls of Caracalla's baths, and many other ruins, the Arbutus and the Rock Rose, the Laburnum and the tree Heath, the Fig and the Honeysuckle, the Olive and the Bird Cherry, the Laurustinus and the Ivy, found a home. The Acanthus, favourite of the column-rearer, carved its own fine leaves far above his capitals, the Maiden-hair Fern came and graced every moist and shady nook; the Giant Fennel was there, in spring, with its large graceful plume; the Clematis and Convolvulus, the Cyclamen (two or three kinds), the Pink, the Everlasting Pea, the Poet's Narcissus, the Crocus, the Mignonette, the Rosemary, the Violet, the Bee Orchis, and a host of others, all grow there too. On the ruins of the Colosseum alone, Dr. Heakin found more than four hundred species of plants sown thereon by passing breeze or bird. With this fact in mind, it is easy to imagine that the number that could be grown on similar positions is almost illimitable. It is not without a useful lesson, apart from that of suggesting how old walls, &c., may be embellished. The plants grow on these ruins much better than on the rock-gardens so commonly made for their accommodation. And the reason is, that the rock-garden, as generally made, is so loose and open in texture that, though the soil may be very suitable, plants perish from drought. On the ruin, such moisture as occurs between the stones is prevented from rapidly escaping by the stones of the surface and the firm texture of the whole. Thus, on the ruin we find a garden, and on the so-called rock-garden too often nothing but clinkers and dust. Recently, with a view of preserving the ruins from decay, the plants have, unfortunately, all been removed from the walls of the Colosseum, but they abound on many other ruins. It was a mistake to remove them, for the walls are avowedly less picturesque, and that the roots of the plants would do harm on such a structure is not proven.

THE BANYAN TREE.

In the Royal Botanic Gardens at Calcutta, there is now a splendid specimen of this famous tree (*Ficus indica*), of which the following account has been recently given by the Director:—"The circumference of the area occupied by the tree, measuring round the outermost stems (with a tape line), is 700 feet, and the diameter between the extreme stems, from east to west, is 200 feet, and from north to south, 189 feet. Many of the branches extend 40 feet beyond these limits. I roughly estimate the area shaded by the tree at about $1\frac{1}{4}$ acre. The main stem is a conglomeration of large trunks, which have united, the whole measuring 48 feet in circumference at 8 feet from the ground. A few of the largest of the secondary stems measure as follows, the circumference being taken 4 feet from the ground: 13 feet, 10 feet 7 inches, 9 feet, 8 feet 3 inches, 7 feet 9 inches, 7 feet 8 inches, 7 feet. A circle has been drawn round the main stem 150 feet in diameter, and all this area is paved with brick; outside this circle there are eighty-one stems, and inside seventy-five.

THE FRUIT GARDEN.

WIRING GARDEN WALLS.

If there is any one improvement connected with fruit-growing to which English cultivators are more indebted to the French than another, it certainly is their system of wiring garden walls and erecting trellises for training fruit trees. It was, of course, to be expected that not a few, and among them many excellent gardeners should still be wedded to their old familiar nail-and-shred system. I am, however, disappointed to find Mr. Baines, of Southgate, among the little band of sceptics. In *THE GARDEN* of March 28th, Mr. Baines says:—"I consider them (wired walls) as great a mistake as has ever been introduced into gardening in a country, like ours, subject to spring frosts." This surely is an assertion quite as plain as it is bold. But what are Mr. Baines's reasons for such a statement? Simply this, that "on wires, with the shoots from half-an-inch to an inch away from the wall, as this system necessitates, a severe night's frost will frequently kill every bloom; whereas, the same trees, if nailed with their shoots lying absolutely against the bricks, will have enough of the bloom escape for a crop." Will Mr. Baines allow me to inform him that he is under a misapprehension in this matter, and that the system of wiring walls does not "necessitate" the wires being from half-an-inch to an inch away from the walls; on the contrary, the wires may be erected by competent workmen so as to be perfectly close to the wall, so that the shoots of the trees may even lie on the bricks, if that were necessary, quite as much as they possibly can do by the now comparatively antiquated and nearly exploded system, which, not even Mr. Baines, can ever bring back again to disfigure English gardens, and harbour dirt and insects. Mr. Baines's preference for splintering the even face of the bricks by having the nails driven into them, instead of into the joints, so obviously, as one would think, in every way offering themselves for the very purpose, along which, in every third joint, say, 9 inches apart, the slender galvanised wires run almost invisible, is to me inconceivable, and to most people must be very puzzling. If the nails do splinter the mortar of the joints, a little bit of mortar applied after the nails have been driven, will make all good again. But not so if the face of the bricks are splintered. The nails, however, need not be driven into the joints at all, if that is any objection, as a gimlet can be used to bore the holes required, and the face of the joints will thus be preserved quite smooth. In some wiring which I have lately had done in my own garden, each line of slender No. 14 galvanised wire, lies along the neat joints of every third brick almost invisible, "as straight as a needle and as tight as a drum." They also lie as close to the wall as a plumb-line, which would surely please Mr. Baines, as being so suitable for the shoots of his trees, which he thinks should almost cling to the wall in order to save them from spring frosts. Having had large experience in the matter of wiring walls, I have no hesitation in stating, that the introduction of this system, and that of erecting wire fruit-trellises, into English gardens has been a marvellous success. There are, indeed, now-a-days, comparatively few gardens of any importance into which wiring has not been successfully introduced, and in almost every new fruit-garden that is made it is looked upon as a necessity.

ONE WHO PRACTICALLY KNOWS.

ROOT-MOISTURE NECESSARY FOR PEACHES.

THE excellent article which you published on this subject (see p. 270), from Mr. Baines, cannot fail to commend itself to all practical gardeners, and I most fully agree with him in his conclusion that drought is the greatest of all enemies to the Peach, and that it is the cause of many of the diseases to which it is liable. We have, at present, two Peach-houses that fully confirm this statement; the earliest is now producing a very heavy and regular crop of fruit, which is stoning on the trees; in the second house, which is just set, the fruit might be counted by thousands; in fact, it is a picture in all stages of growth. Five years ago, when I first saw these trees, they were miserable objects, suffering from Fungus at the roots, brought on by nothing else than lack of moisture, as the

border, houses, and trees, were new, and in every respect excellent. Several ineffectual attempts had been made to fork the Fungus out, but as the border and roots were quite white with it, this was impossible. The leaves of the trees turned white, drooped under sunshine, and fell in showers under the syringe, and whole branches continued to die out as if paralysed. The Fungus was strongest where the border was driest near the hot-water pipes and entirely absent at the back of the house, where the drip from the shelves kept it saturated; I, therefore, resolved to try the water cure, which proved entirely successful, for not only have the trees filled every inch of space that could be made available, but have annually produced excellent crops of first-rate fruit. It is, however, in the cultivation of Peaches on open walls to which Mr. Baines specially refers; and, that they can be grown in that way, I think the most sceptical would agree, if they could just look at our open Peach walls now, when they are complete sheets of blossom. Our system of cultivation is identical with that recommended by Mr. Baines. I would also direct especial attention to the remarks on nailing close to the wall, which are applicable to all kinds of wall trees; for the extension system of pruning, especially with regard to spurs, has been carried to such a length that the object for which the tree was originally planted against the wall appears to be lost sight of.

JAMES GROOM.

ROOT AND TOP GROWTH.

A CORRESPONDENT has put to us the question, "When do Vines begin to make fresh roots?" In answer, we propose to offer a few remarks which we hope may prove instructive to others as well as to our correspondent. We will not, however, confine our remarks to Vines, but will refer to what have been our observations and experience in connection with the reciprocal growth, and *vice versa*, of other plants as well. Our correspondent's query regarding the time at which Vines begin to extend new or young roots into the soil, it is taken for granted, is in reference to Vines in the most normal condition in which they are to be found in a Vinery. This condition, we should say, is that of a healthy Vine in a good border, and one which is not forced, say before the 1st of March, and is not subjected to artificial heat at the roots. Our observations with regard to such a Vine lead us to reply that it does not begin to push out young roots until the Vine has produced young growths quite a foot long, and so far expanded some leaves: and the older the Vine and the thicker its stem, the more will the top grow before any formation of roots takes place. On the other hand, a young slim Vine begins to make new roots before the young stems and leaves attain the length named in the case of an older Vine. The stored-up sap in a given length of the young slender Vine is less than in one that is older and stronger. There are what shall be termed abnormal conditions, under which Vines, both young and old, deviate from what has been stated above. When bottom-heat has been applied to the border at or before the time the buds begin to burst and grow, then Vines begin to root at an earlier period, or even contemporaneously with the top growth. When a Vine is in a border that is heavy, retentive of moisture, and in which the younger and very important fibry parts of Vine-roots die back annually, the commencement of the growth of roots is still later in proportion to the top growth than we have stated. We once rooted out Vines that had approached to their flowering period, and did not find a single young white root in the border, which was cold, damp, and adhesive. Much also depends on how the roots have been ripened the previous autumn. The ripening of Vine-roots is a question of vast importance in Vine culture. When anything occurs to prevent their proper maturation—such as the premature loss of the foliage—the roots never shrink properly up into tough brown fibre that can stand the winter, but die and rot off altogether. A Vine with properly ripened roots will start both its roots and tops more nearly contemporaneous than one the roots of which have been killed, not ripened. A Vine in pot grown under good drainage and in firm soil makes roots earlier than one grown in a badly drained pot and loose wet soil. If a Vine in a pot is started without bottom-heat, its top growth will be 8 or 10 inches long before it begins to root afresh. If the pot is plunged in bottom-heat the roots will start earlier of course, and sometimes they start before the tops, if the tops are cool while the roots are warm. We, however, regard it against the order of nature, and not good practice, to cause a Vine to make fresh roots out of its natural time or order. We dare say many of our experienced readers have noticed over and over again, in forcing Vines with their roots in an outside unheated border, that they made a certain amount of growth with

considerable rapidity, stood still for a while and then started away somewhat abruptly. This is caused by the stored-up sap being exhausted before the young roots are formed to pump up a full supply of sap to the young growths. This is most strikingly noticeable in the case of Vines in a cold retentive border, where the young fibry roots die in greatest proportion in winter. Such ought to be forced, when forced at all, very cautiously, or the results will be most unsatisfactory. To draw out their young growths rapidly by force of fire-heat causes the growth to be weak indeed. The best course to pursue with such Vines is, either to retain the heat of autumn in the soil, or heat it by some other means,—place a bed of fermenting material inside the Vinery, and keep up the heat with as little fire-heat as possible, and, with good inside generalship, it is marvellous with how little roots, we have known a crop of Grapes matured from such Vines in May and June. We have taken out borders, where such has been the case, immediately after the crop was cut, and could find next to no fibre in it—a most desirable state of things, however. It is most astonishing what growths will take place under certain circumstances without any roots at all. We have at the present moment some pieces of the common Hazel hung up in a damp stove, that have growths six or seven inches long, and callosities formed at their butt ends. Then look at a "Vine eye." It will make in some instances young shoots, with leaves, three or four inches long, before a single root is sent out; while, on the other hand, we have had Vine eyes—something being wrong with the bud—that never started at all—but the stored-up sap, not to be baffled or wasted, has sent out a whole bunch of roots, thus going out of the ordinary course in making a desperate effort for life. And so, as a rule, we think it questionable practice to apply conditions that cause—in the case of deciduous plants—root growth before top growth: it is the wrong way of making use of stored-up sap.

Perhaps it has not occurred to some of our readers that most deciduous trees make the full length of their season's growth in a very few days. There are, for instance, the Horse Chestnut, the Lime the Sycamore, the Beech, and many others, that burst their bud cerements, and extend their season's growth at a bound. And many of them attempt the same, even though entirely severed from their roots. We have seen some trees felled in autumn making growths a foot long in early summer. And it is after this production of young branches and leaves that the chief manufacture of young roots takes place. This ought not to be without its lesson to gardeners in the culture of deciduous plants in pots. Take, for instance, the Vine; it has to be shifted out of a small pot into a larger. The operation should be done not when it is dormant, but either before the root growth has ceased in autumn, or just as the new roots have commenced to grow in spring. Or, if Vines in a border have to be lifted and re-planted, it should be done before the leaves fall off, so that there is a chance of young roots biting into the new and congenial soil, or the work should be delayed until the buds are swelling. So, in shaking out a cut-down Vine in spring, we would not interfere with its roots while the bud or buds have not burst, but would let the top growth form a few leaves, and then shake it out, or re-pot it just as the roots are going to start. The fact of the rule, that the growth of roots and leaves is reciprocal, ought to be of much more service in garden practice than it is. The practice, for instance, in forcing deciduous shrubs into bloom in spring, of lifting them just a few days before they are wanted to force, and potting them up with mutilated roots, is far too common. It would be much more in accordance with their nature and habits, if they were kept constantly in pots, or carefully lifted before they shed their leaves, and be shaded and syringed for a time, so that their leaves would suffer as little check from lifting as possible, and insure their laying hold of the fresh soil before they throw off their leaves. Take, for instance, the case of a Rose. Lift it and pot it after all its leaves have dropped off, and let it be forced after such treatment, and the result will be unsatisfactory as compared to another that is lifted in October, while it has yet leaves, and its pot plunged in a gentle bottom-heat for a time, while the top is kept cool. Under such conditions it takes a hold of the soil before the leaves are shed, and it forces vastly more satisfactorily than when managed on the other plan. It is perfectly well known that deciduous plants can be made to manufacture young white fibry roots immediately after their leaves are shed, and with very wonderful rapidity too. But this takes place under unnatural circumstances, and is the reverse way to that of nature in making use of stored-up sap. Let a Currant bush be lifted and planted in the inside border of a warm Vinery, just immediately after it has shed its leaves, and it will soon have young white roots squeezed out of it without a single bud moving for weeks; and when they do move they are weakly and delicate. But let the same bush remain in the open quarter, and it forms its young growths at a bound, while the young roots are not so forward

as those made in the Vinery, till the bush is well clothed with leaves. Hence we conclude that root manufacture in deciduous plants, while leafless, is only an exhaustion of the stored-up sap at the wrong end. This relation of root to top growth teaches us another lesson which is well understood in plant culture. Take, for instance, a Pelargonium, or even a Camellia that has to be cut down so as to denude it of all foliage—the object being to get the plant to burst into growth nearer the pot, and prevent it from becoming straggling and unsightly. It is at the same time in exhausted or improper soil, and it is necessary to its future well-doing that new soil should be supplied to it. If the plant be shaken out of the old soil when it is cut down and denuded of every leaf, there are ten chances to one that the plant will die. So complete is the reciprocal action of leaves and roots, that it will neither produce the one nor the other. The plant should be either shaken free of the soil a time before it is cut down, or allowed first to burst into fresh growth, and then operated on at the root; the latter, for several reasons, is the better way, and the most convenient. A tender plant will not stand, without risk of total destruction, the contemporaneous mutilation of both its roots and leaves; but if the one is left intact, it so far survives the other as to make a successful effort to restore the balance. Evergreen plants, such as Oranges, Camellias, &c., have a particular season at which their roots elongate or increase with more rapidity than is usual at other stages of their growth; and in ordinary circumstances that season is after they have made their growth, which they do in a comparatively limited period. This is the most desirable time to shift such as require it into larger pots, for the roots will then extend most rapidly into the fresh soil.—*The Gardener*.

AIR-ROOTS ON VINES.

I VISITED the Vineries of Messrs. Baker & Son, at Worthing, the other day, and was surprised to see the numbers of air or stem-roots which their Vines were producing. Their houses are span-roofed, 10 feet wide and 90 feet long, with sunk centre, the platforms rising nearly to the spring of the roof, which, in the centre, is only 3 feet above the bed or platform. On my previous visit, at Christmas, Grapes in good condition were being cut in one house, and the Vines in one of the others had just started. This house, I now find, contains 1,600 bunches of Grapes, all nearly full-grown, the fruit and bunches of good size, and some beginning to show colour. There is a peculiarity with these Vines which has not before shown itself here, and which gives them a most singular appearance when looking down the length of the house. From every joint air-roots have started, and have grown about 9 inches in length. On some joints there are as many as forty, but the amount varies down to about ten or twelve. The variety is the Black Hamburgh, which has always borne freely, but, hitherto, without these air-roots; the latter appear to me to arise from damp. Owing to the Vines being so near the soil of the platforms, the joints have been stimulated to throw out rootlets, which look as if they would soon enter the soil. What ultimate effect such an excessive growth of air-roots will have remains to be proved.

C. J. Cox.

[Air-roots on Vines are by no means uncommon. A damp atmosphere, doubtless, encourages their growth; but it seems to be the nature of Vines to throw out such roots, and some varieties do so much more freely than others.—Ed.]

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Young Apple Trees Best.—The experience of an American orchardist, says the *New York Tribune*, illustrates the advantage of planting young trees. Eight years ago, he set out one, two, three, and four-year old Apple trees on the same day, and in the same soil. The first Apples, of course, came from the oldest trees, but at the present time the one and two-year old trees are the most vigorous, and have borne, in the aggregate, the most fruit.

Golden Champion Grape.—Like your correspondent, "N." (see p. 314), I have also failed in fruiting this Vine successfully. I have it growing here on its own roots, in a house planted chiefly with Hamburgs, and though a strong grower it seems to be a shy bearer. In 1872 it never showed any fruit, last year one bunch, and this season four bunches. I am inclined to work another variety upon it; will any of your readers kindly inform me what sort would do best on this stock?—J. M.

Orange v. Grape Culture in California.—It is announced, says the *New York Tribune*, that Grape culture has become so unprofitable in some parts of California, particularly in Los Angeles County, that the growers are tearing out the Vines and planting Orange trees in their places. One noteworthy Vineyard, the Wolfskill, thirty-five years old, is said to have been kept up for some time past at a loss to its proprietor of about 2,000 dollars per annum. Others in the same neighbourhood have yielded no profit—a statement which will readily be believed when it is remembered that the Grapes sold last season at from 50 to 65 cents per 100 lbs., a price barely covering the cost of production. Great expectations are entertained of success with the Orange (some experiments in raising them having proved very remunerative), and we trust they will be fully realised.

THE LIBRARY.

THE HEART OF AFRICA.*

No more important work on the natural productions of the great unknown countries of Central Africa has appeared than that contained in the two goodly volumes by Dr. Schweinfurth, recently issued by Messrs. Low & Co. This intrepid and highly-gifted traveller, but for the eventual insufficiency of copper bars, wherewith to meet the tribute insisted on by native chiefs, would have succeeded in reaching the point at which Livingstone's advance from the south-east terminated; and would have been able to lay down on his map the sources of the Congo and those other great rivers which have their origin to the south of the watershed of the Nile streams, and which find their outlet to the sea on the west coast. Advances, occupying scarcely two or three months more, would have effected this purpose, and the whole mystery of the interior of the vast African Continent would have been solved. This, however, was not to be; and our stalwart traveller, still in vigorous health, was compelled, in deep disappointment, to retrace his steps northward, leaving to others the glory of seizing the prize, which was so nearly within his grasp. Dr. Schweinfurth has, however, done enough, and to spare, to ensure his fame and establish his position as one of the most accomplished and successful travellers of our day. With many scientific attainments, a robust constitution, and plenty of daring, combined with prudence, he was just the man for the enterprise, of which his valuable volumes form such an accurate and complete record; the fact of his being the first true botanist rendering his statements still more valuable. In the brief space of a review, it will not be possible to follow the explorer during the whole of his route, which can only be touched upon at a few detached points of his adventurous journey.

As he approached the Port of Suakin, on the Red Sea, at which point he intended to disembark and advance towards the course of the White Nile, he observed that "a green carpet of Samphire covered the coast for miles along the land." The generic name of its family (*Sueda*) is a word initiated from the Arab *Sued*, from which we obtain the name of the well-known product, soda. This abundant Samphire region has, it seems, long been turned to profitable account by the Arabs, and, doubtless, an important trade might be established by English enterprise. As he travelled inland, he found that the mountains between Suakin and Singat afforded a habitat for numbers of remarkable plants; among which the most striking forms are those of the *Dracæna* and *Euphorbiæ*, remarkable especially for their fantastic shapes. They flourish on lofty heights, and are not found at less altitudes than 2,000 feet above the valleys. These Nubian Dragon trees are, it is true, but dwarfs in comparison to their sister of Oratava, in Tenereffe, but yet form very remarkable features among the vast stone boulders of this Nubian mountain range. The *Dracæna* or Dragon tree is known in Nubia as *To-Omba* or *T'Ombet*. The annexed engraving will convey, with considerable accuracy, the impression of the scene as described by our author. Between Singat and Khartoom, where the advance south was to be commenced in earnest, Dr. Schweinfurth found rich botanising quarters at many points; the vegetation of the hill districts being somewhat analogous to that of Abyssinia, which has been termed the Switzerland of Africa; while in the low-lying regions he found the trees and herbaceous plants approaching in character those of the Nile valley, and occasionally resembling the inter-tropical flora. In the mountainous districts to the south of Suakin he met with the most luxuriant vegetation at great elevations, especially on a mountain, 6,000 feet high, at Erkoweet, where the clusters of Beard Moss, and the abundance of sulphur-coloured Lichen give a peculiar aspect to the scenery. The wild Olive is also abundant in that neighbourhood, and entirely disappears in the interior of the great Continent. In the Wady Amet district, a species of *Scrophulariaceæ* grows, which had been honoured with our botanical traveller's name, as *Schweinfurthia Pterosperma*, and which he

* "The Heart of Africa." Three years travels and adventures in the unexplored regions of Central Africa, from 1868 to 1871. By Dr. Georg. Schweinfurth. London: Sampson Low, & Co. 1873.

says met him like a pleasant greeting from his distant home. Before reaching the confluence of the blue and white Nile, many portions of the great Nile stream, with its islands, are described with considerable graphic power; but we must pass at once to Khartoom, where, with a protective firman from the Khedive, he made his arrangements in respect to bearers—that is to say, porters—to carry forward his presents for native chiefs, his gunpowder, his scientific apparatus, clothing, and provisions. Added to the porters, a certain number of armed Nubians was necessary, and these he obtained from the Arab ivory merchants, whose *seribas* or stations, far in the interior, are numerous, and require soldiers to protect them; the southern Nubian forming good material for a military force of that kind. During the first day's journey on board a Khartoom Nile boat our traveller, advancing up the stream, noticed how the once impenetrable forests had been thinned, to the verge of destruction, for fuel and boat-building purposes; and also, in contradiction to the less accurate observations of Sir Samuel Baker, that the soil was nearly as

weight of this valuable article of commerce in a single day. Entering the Bahr-el-gazal, the course by which they were to reach Mezhera, the stream became almost choked up with numerous small islands, some floating and others permanent, the shores being covered with forests of exquisitely beautiful Ferns of many kinds. From Meshera the start took place, by land, for the *seriba*, or station, belonging to Ghatta, a great Khartoom ivory merchant who had engaged to aid his farther progress by means of caravans proceeding southwards to collect ivory. It was, in fact, the aid of these Khartoom merchants, Ghatta and others, that enabled the traveller to make his way to a farther point southward, advancing from the north, than had yet been reached by any European. Vast stores of botanical wealth, many of the specimens being entirely new to European science, were accumulated during successive advances, and forwarded by returning caravans to Europe. They form an immense mass of novelty in regard to plant life; and the publication of their scientific description, accompanied by the necessary amount of accurate illustration, will be expected with

Dragon Trees in North-West Africa.

fertile as that of the Blue Nile, and that the common Sorghum vulgare yielded ears of grain at least 4 inches long. He was much struck, as they advanced, with the luxuriant foliage and bright pink flowers of *Ipomæa asarifolia*, which covers large tracts of country like a Rose garden. The *Ædemone mirabilis*, grows profusely in the shallow waters, the wood of which is so light that, though growing to a height of 15 or 20 feet, large plants frequently get detached and form, with other vegetable accretions, those floating islands for which the upper portion of the White Nile is so remarkable. Eventually, when far beyond the frontiers of ancient Egypt, our botanist came upon vast tufts of Papyrus, once so plentiful on the main stream of the Lower Nile, and furnishing the only writing material of the old Egyptians, but which is now as extinct in those waters as salmon is in the Thames. Farther on the *Acacia* groves attracted notice. These plants produce gum in such amazing quantities, that in the interests of commerce they ought to attract European notice. It appears that in the winter time one man might collect at least a hundred-

impatience by all European botanists and men of science. The course of the traveller's advance from Dyakin to the *seriba* of the friendly merchant, Ghatta, is very clearly shown on the map attached to volume I.

One of the chief and most natural means of travelling in Central Africa ought to have been the native elephant, which is being rapidly and ruthlessly destroyed for the sake of his ivory tusks. He is larger and more robust than the Asiatic species, and in the days of Ethiopian splendour was successfully domesticated. By means of these animals Dr. Schweinfurth thinks that communications and free trading with the very heart of Africa might be regularly carried on by Europeans far more conveniently, and in a way more tending to the gradual civilization of the country than by the present means of Arab commerce, enforced by demoralised and demoralising Nubian soldiers. At Meshera, an unhealthy station, where a considerable stay was made, the *Kegelia* was in full bloom, its flowers having somewhat the aspect of Tulips, while the growth of the trees resembled that of the European Oak.

Here, too, was found the most southerly boundary of the *Abizzia seracifolia*, with its clusters of white blossoms, like masses of snow-flakes. Throughout the Dinka district, the preparations of farinaceous and milk foods were not found inferior to those of the European *cuisine*. In fact, with the exception of the comparatively modern inroads of negro barbarism in certain districts, striking remains of a civilization, evidently derived originally from ancient Egypt, were apparent. Across vast districts of Steppes of considerable aridity, a rocky and more elevated region was next reached, where the air is described as highly salubrious, and the country luxuriantly fruitful. In the vicinity of Ghatta's Seriba extensive stretches of country are being highly cultivated. Ghatta's domains contain 200 square miles, with a population of some 12,000 native inhabitants, forming a territory which in Europe would be worth millions, but which might now be bought, as we are informed, for 20,000 dollars. Such purchases will, doubtless, be even tually made by English enterprise, and civilization and successful commerce will necessarily follow such undertakings, if backed by sufficient capital.

Dr. Schweinfurth describes his botanical excursions as he advanced as being full of interest; and his health being robust, he falls into transports of joy at his discoveries, and declares himself fairly "enraptured with the unrivalled loveliness of Nature." The forests eventually became scarcely mutilated at all by reckless destruction for fuel, as in the more northerly regions he had passed through, and were extremely beautiful; and at one spot the tall *Uncaria* and *Eugnia*, their tops crowned with spreading foliage, formed a grateful shade, in which great thickets of red-blossomed *Melastomaceæ*, mingled with giant *Aroideæ*. Here, too, was found in abundance the large *Candelabra Euphorbia*, and many trees adorning the hanging rocks are described as yielding edible fruits, such as the *Göll*, for instance, which bears pods like those of the *St. John's Bread*, the wood being used for carved stools, boxes, and other articles of native furniture. There is also the *Strychnos edulis*, with fruit resembling a Pomegranate, from which a beverage, something like, and as refreshing as, lemonade, is prepared.

Here the traveller planted a kitchen garden in the European style, and sowed the seeds which he had brought from Europe, most of which thrive well, and realised his expectations, with the exception of Wheat, which failed. The Tobacco plant, from Virginian seed, attained to great size, with leaves larger than he had ever seen. This garden yielded him much pleasure, and in its immediate neighbourhood, seated under a great tree, he passed many happy hours and days in classifying his botanical specimens, having collected above seven hundred species in five months. Among the bulbs were *Hæmanthus*, *Gloriosa*, and *Chlorophytum*. There were also many ground Orchids, and also the wonderful *Kosaria*. Wild Vines abounded; which, no doubt, by future European enterprise, will be made to yield wines of flavour and character yet undreamed of by our connoisseurs and wine merchants, for we must remember that the American Catauba wine, made from the wild Vines of the Ohio, was utterly unknown and unimagined only a few years ago. Our traveller called his residence at Ghatta Seriba "an idyl of African nature."

An interesting account of the different kinds of Sorghum, African Millet, and other farinaceous grains, is given in these volumes; and the author expresses his astonishment that Rice has never been introduced by the Arab merchants, as many districts are highly favourable to its growth, and the population, as proved by their management of their native grains, are skilful and industrious cultivators. One among the very many interesting statements of Dr. Schweinfurth is his belief that nearly every kind of illness which attacks Europeans in Africa belongs to one or other of the many forms in which malarian fever shows itself; and that quinine, if regularly taken at the rate of ten grains a day, is a nearly certain preventive of any serious attack. The next advance brought our traveller to a point commanding a view of the plains through which the Tondo pursues its course, the more striking features of vegetation being a large-leaved blue-green *Anona* and a handsome *Grewia*, with many winter-flowering shrubs, especially an *Echinops*, with purple flowers as large as a man's hand. In these extensive plains are huge stones as large as rocks, but

smooth as marble, and in the hollows a vast variety of plants of different kinds. The territory and national character of the Niam-Niams are graphically described, as well as the flora and arboreta of that region; and, in alluding to the rivers Roah and Kuddoo, he dilates, with evident delight and a true appreciation of the picturesque, on the meeting of the trees growing on the steep banks over the stream, forming tufty bowers, at a height of 80 feet above the water; while the narrow passages through luxuriant woods, to which he gives the name of galleries, are described as of unapproachable richness of aspect. The luxuriance and height of the Grass called *Popukky* is dwelt upon as he advances deeper and deeper into the heart of the country, as well as the beauties of the charming halting-places, surrounded by Zawa trees and the noble *Lophira alata*, which Grant met with on another route, and declared its discovery to be the fairest memorial of his African travels.

Reaching at last a range of hills which, from their geographical position, as well as from the assurances of Niam Niam guides he believes to be the true water-shed of the Nile and its affluents, he declares that day to be the most memorable of his life; and he is afterwards confirmed in his theory by the discovery that the Welle, and other important streams to the south of that range of hills, flow directly towards the west, and are, undoubtedly, as he thinks, the parent stream or feeders of the Congo, the Niger, and other great rivers that find their outlet on the western coast. Still proceeding southward with the caravan of Aboo Sammat, conducted by his agent Mahomed, he found unlocked to him, as he expresses it, new and untold botanical wealth, and as he gradually approached the southernmost limit of his journey, the country continuously increased in beauty and interest, insomuch that he declares, in his enthusiasm, that the last twelve miles, which brought him to the previously unknown Monbuttoo country, "were enriched by such beauty as might be worthy of paradise."

His reception by King Munza, whose chair of state recalls, in form the thrones of the Pharaohs, and his astonishment at the dimensions of the great hall in which he was received, combined with the discovery that a region immediately to the south of the Monbuttoo country was the land of the pigmies, whose descriptions by ancient authors was considered fabulous, filled him with ambition to proceed southward without delay. But this crowning success (another month's advance would have taken him, through an entirely unknown country, to Livingstone station) was denied him. King Munza refused to let any caravan pass through his dominions, lest his own command of the southern ivory traffic might be interfered with. Finding his means insufficient to bribe this potentate, he reluctantly, after lingering long at this farthest point of his wanderings prepared to retrace his steps. While there, however, he obtained as a present from the king one of the pigmies, whose name was Adimokoo, who informed his new master that his nation which he so much longed to see, was that of the Accas. It is impossible in the limited space of a review that a hundredth part of the interesting and important information acquired by Dr. Schweinfurth can be even alluded to; but it may be stated that these volumes will do more to open up the interior of Africa to civilization and commerce, than the works of any modern traveller, not even excepting those of our great and intrepid explorer Livingstone; for Schweinfurth has shown how the way from the north to the great central highlands has been laid open by the recent advances of the great Arab traders, and still farther facilitated by the triumphant exertions of Sir S. Baker. Dr. Schweinfurth's work will be read and carefully studied by all who are anxious to clear up the darkness and mystery which has so long shrouded the core of the great African continent. He has shown that only in certain parts, as in the case of the Gold Coast, is the climate unhealthy; and, for malaria of that kind, clearance of forests, drainage, and, possibly, the application of a true "botanical" cure, the plantation of the Australian gum tree (*Eucalyptus globulus*) may, as it has done in other places, tend to remedy the evil very effectually. We hear of the cure, by means of drainage, being successfully applied to the Pontine Marshes, and to the banks of the Thames about Erith and other places, where the several forms of intermittent fever raged perennially, only a few

years ago, after a truly pestilential fashion. While, as regards our valuable settlements on the West Coast of Africa, it has been the prevailing fashion to talk of "abandonment" instead of "cure." But the announcement of Captain Glover, fresh from the region itself, that thirty miles inland from Accra "men may dig gold like Potatoes," will tend more rapidly than any other kind of argument or persuasion to dispel the half-hearted and puerile dread of a climate which the industrial hand of man may render comparatively healthy. While, moreover, it is now known that at a very short distance from the coast line the climate becomes rapidly healthy in proportion to gradual elevation of the land; a fine open country having been found the prevailing character in many places at a comparatively short distance from the sea coast.

GARDEN DESTROYERS.

GARDEN PESTS.

By T. BAINES, Southgate.

The Gooseberry Caterpillar.

THE locust-like appetite of this caterpillar renders it most destructive to this useful fruit. The way that a brood of them will completely strip a tree of its leaves in a few days, is really astonishing, leaving nothing but the bare wood, and fruit which the loss of leaf renders worthless. The trees are also very much weakened by the unnatural condition they are reduced to, and, unless the larva is destroyed, the trees are almost certain to be infested with caterpillar the succeeding year, for before the perfect insect takes flight, she will deposit her eggs on the trees, which will quickly come to life, repeating similar destruction to that of their progenitors the year previous. As soon as they are observed, means should at once be taken for their destruction, for, if allowed only a few days, in addition to the injury they do, they are much more difficult to deal with. For some days after they first come to life, they are comparatively tender, and easy to kill. As they get older, they get strength, and are not so easy to destroy, and they also spread over the tree, which necessitates the whole of it being dressed with whatever is used for their destruction. Anything of a dry dusty nature they dislike; even dry road dust will render the leaves unpalatable to them, and cause them to drop off, but, unless they are killed whilst on the ground, they quickly crawl up on the trees again. Air-slaked lime, if applied whilst they are young, from its caustic properties, will destroy them; but the trees should be examined shortly afterwards to see that none have escaped, as, if heavy rain falls soon after the lime is applied, it gets washed off, and some escape. There is nothing so effectual as a mixture of powdered white hellebore and whitening, applied to the trees with an ordinary flour dredger, first thoroughly wetting the whole of the tree with the syringe to cause the powder to stick. The hellebore (to be procured at any druggist's, but it should be freshly ground, as it loses its efficacy if kept long) should be used in the proportion of 1 lb. to 6 of whitening, ground fine, and well mixed together; this will destroy every caterpillar in a few days, even if they have grown large and strong. But the hellebore is poison, and wherever it is used, care must be taken that the whole is washed thoroughly off with the syringe or garden engine after the caterpillars are killed, or the fruit would cause bad effects upon anyone eating it, the very idea of which causes many not to use it. I have frequently used it myself without the fruit being in the slightest affected with it afterwards, but was always careful to see that every trace of the powder was washed off. A good preventive is, in the winter, when the trees are at rest, to put a spadeful of lime on the surface of the soil under each tree, spreading it out from the collar under the branches. This will kill the larvæ, which at this season are lying dormant under the soil, to which they have descended from the branches, after having completed the length of time they were destined by Nature to remain above ground, and from whence, if not destroyed, they will emerge and take wing, when the females will deposit their eggs on the trees, which, in due course, will come to life, and repeat similar destruction of the leaves.

The Rose Maggot.

The maggot is very annoying to the Rose grower, boring into the best buds, and destroying many a cherished hope of first prizes. There seems to be no possibility of escape from it; every year it makes its appearance, and, if not destroyed in the spring as it comes to life, scarcely a perfect flower will be obtained, especially early in the season. At the time of pruning, every bit of the prunings, with the pips, if any remain, should be carefully gathered up and burnt. As soon as the shoots begin to push, and the leaves expand, the larvæ will make their appearance; they may easily be detected by the web they spin, coiling themselves up in the young leaves. It is here they must be looked for with care and destroyed, going over the trees once a week, crushing them with the fingers, for if allowed to remain, as soon as the buds make their appearance they will spoil them. In the usually confined beds of the amateur, and over-sheltered Rose-gardens of private establishments, this insect is much more prevalent and destructive than in the extensive open grounds of the grower for sale. The more exposed situations of the latter appear to be uncongenial to this and other insects that infest the Rose, for an account of which see an illustrated article at page 26, vol. iv., of THE GARDEN.

The Apple Boring Grub.

This insect is the bane of this, the most useful of all fruits grown in this country. Soil and situation, trees small or large, appear to have no immunity from it. When the sanguine fruit-grower has seen the blooming season safely past, congratulating himself upon having escaped the frosts of our fickle spring, and reckoning upon his trees being bent down by the weight of the crop, he often sees many of his best trees drop their fruit by hundreds, until nothing more than a scanty crop comes to maturity, and many of these more or less deformed. The insect comes to life during the spring in due course, first feeding upon the leaves, and afterwards attacking the fruit, boring straight to the core and devouring the pips which causes the fruit to drop off. In the case of large trees little or nothing can be done. With dwarf bush or pyramid trees they may, with a little attention, be much reduced in numbers by going over the trees in the spring and destroying the larvæ as soon as they come to life whilst they are confined to a limited space, being first enclosed in large spider-like webs before they make their exit, from which they are easily destroyed, but if once they escape and become dispersed over the tree little can be done.

The Onion Maggot.

This is the larva of a fly that deposits its eggs amongst the leaves of the plant, and works its way down to the bottom of the bulb; and, when they attack the crop, they most generally destroy or seriously injure it. The Onion is much more subject to the maggot in light soils than in heavy land, especially in old worn-out gardens. I have tried various remedies that have been recommended for its destruction, or as a preventive to its spreading; but I have never found anything that was of use after it once attacked the crop. By a judicious preparation of the soil, and the use of some manures, I have found that its attacks were rendered less frequent. In light land, the addition of liberal quantities of new soil, with a good dressing of salt (half a pound to the square yard), applied as a surface-dressing during the autumn or winter, with an inch of soot pointed into the ground before sowing, renders the crop less liable to its ravages. It would appear that the smell of soot is distasteful to the fly, and prevents it depositing its eggs; but, whenever they have come to life, the soot-dressing overhead, often recommended, I have found of no avail.

The Cabbage Caterpillar.

This insect is much more dependent on seasons than some others. If we get unseasonably warm weather early in the spring, by which the insect is fully matured and takes wing very early, the chances are that these early butterflies are all destroyed by a frosty night ere they have had time to breed and deposit their eggs. In such seasons we are comparatively free from such as attack the early crop. Later in the season we generally get the larger, more beautiful marked

grubs of the late season, and still more beautiful butterflies, Cauliflowers and tender summer Cabbages are their favourites. yet they also attack Savoy, winter Broccoli, and other varieties of the Cabbage tribe; and, if left unmolested, will quickly leave little more than the stronger and more fibrous parts of the leaves, rendering the plants useless. Sometimes the practice of dusting the leaves over with lime is resorted to; but, unless the plants are attacked whilst very small, it gets into the hearts, rendering the remedy as bad as the disease. Nothing equals hand picking, beginning as soon as the insects come to life, for which a diligent look-out should be kept, as for some days after they come to life a whole colony will be confined to a single leaf, in which condition they can be destroyed much more effectually and in a tenth of the time it takes to find them when dispersed over the plants; but, even if they have dispersed before their presence was detected, they should be diligently sought for and destroyed, for, if left unmolested, they will cause a gap in crops that in private establishments cannot be spared, to say nothing of the unsightly evidence of careless gardening, which vegetable crops reduced to this plight present.

The Celery Grub.

This is a leaf-boring insect, and, almost every summer, makes its appearance amongst the crop, either more or less. The female punctures the leaf, and deposits her eggs under the cuticle, where they come to life and feed securely, destroying a considerable portion of the leaf; if left undisturbed, doing serious injury to the crop. The position occupied by the insect renders any outward application ineffectual to reach it. There is no method that I have ever tried, except going over the crop and crushing them between the finger and thumb. A man will go over a good deal of ground in a day; there is no difficulty in discovering the whereabouts of the insect, as its presence can be easily detected.

In the foregoing papers on the principle insects, &c., that prey upon cultivated plants, the means I have narrated for their destruction are in all cases such as in practice I have proved to be the best out of numbers tried. For every insect that gardens are infested with, numbers of means are often recommended for their destruction that in practice are found ineffectual, or that are so far injurious to vegetable life as to render the cure as bad as the disease. I have also tried to make them as plain as possible by avoiding all scientific nomenclature, and giving in each case details which, I trust, will be sufficient to enable anyone to operate without danger of injuring the different plants affected. But it must always be borne in mind that in dealing with minute animal life, which we wish to thoroughly eradicate, no half measures will suffice; it must be a war of extermination, which nothing but perseverance will bring to a successful issue. And, in the case of numbers of garden pests, it is a campaign that must be fought annually and with determination wherever high-class gardening in any branch is attempted.

MEIKLEJON'S CRUCIFORM BOILER.

ALTHOUGH coals are considerably cheaper now than they were twelve months ago, the economical heating of plant-houses is still a subject of much importance, and one concerning which boilers play a prominent part. Of these, various forms are before the public, and as all claim the merit of superior excellence, a few words respecting a really useful boiler may be of service to your readers. A trial does not always confirm the representations made concerning them by their inventors.

Meiklejon's Cruciform Boiler.

To produce the greatest amount of heat from the smallest quantity of fuel, is the true characteristic of a good boiler, and the possession of this desirable quality cannot be ascertained in a few hours, but only in a trustworthy manner from a hard winter's firing, or a more lengthened period of trial. I therefore place but little faith in the results of boiler competitions. After having for a long time in use various medal takers, circulators of all descriptions, cannons, retorts, saddles, upright and downright tubular boilers, I unhesitatingly give the preference to the cruciform boiler, of which the accompanying are illustrations. Our present working-stock of this kind of boiler consists of four, in addition to as many more of other sorts, and we find it to be one of the most economical and efficient boilers yet constructed for general purposes. It may be had of any size required. The different sizes with us are heating effectually from 500 to 2,000 feet of 4-inch piping in Pine-stove ranges. The fuel required for them, is not half the quantity consumed to produce the same amount of heat by other apparatus of much greater pretensions. Its construction, as will be seen, is simple; resembling four saddle boilers cast together. The accompanying little

Diagram showing how the Boiler is set.

diagram represents a back view, and shows the flow-pipes and the sockets for the return-pipes. The larger illustration exhibits the whole fitted up, with a few bricks of the setting removed to expose the interior arrangement. The fire is placed under the lower angle, the flames from which pass to the back, where they are divided, and traverse the two side angles before coming to the front; there they are again re-united, and make their exit along the top of the flue, in contact with the flow-pipes from the boiler. In a No. 1 boiler, which is 4 feet long, upwards of 60 square feet of heating surface are thus fully exposed to the action of the fire. Another of its valuable adaptations is, the shallow stoke-hole in which it can be placed. Where a bottom-heat pipe has to be taken from the flow, deep boilers are virtually

unservicable, unless where a depth of drainage exists, which is not always to be had. The material of which this boiler is made is cast-metal, and, under all manner of adverse circumstances, I never yet knew one to fail. The cost too, which is generally a consideration, is, for one of these, small compared with that of some other boilers.

Clovenfords.

J. MUIR.

Glass for Greenhouses.—Will you, or any of your correspondents, tell me what is the very best kind of glass for a well-built house for greenhouse plants? —J. H. H. [The very best glass for general gardening purposes is 24-oz. British sheet.—Ed.]

THE KITCHEN GARDEN.

CROPPING A KITCHEN GARDEN.

HAVE two plots of ground which I wish to turn into a kitchen garden, one 37 feet square, and the other 39 feet by 35 feet. Will you kindly inform me how to begin, and how to continue to cultivate the same, having regard to the fact that I wish to have as great a variety of early vegetables as possible, of the best quality?

AMATEUR.

[On submitting this question to Mr. Baines, an excellent authority on such matters, he has kindly furnished the following reply:—Your correspondent's question, although relating to a limited space, to be of any use, requires a much more lengthened answer than at first sight might be supposed necessary. From the total absence of any indication as to the nature of the soil; the situation, whether cold and shaded, as such plots nearly always are; if in the rear of a house with a south aspect; or, on the other hand, if the ground is more favourably situated, so that it commands the sun for the greatest part of the day. The absence of such data renders it a difficult task to give advice on the subject, inasmuch as the difference in the conditions indicated render the proceedings necessary to secure success very different. We must suppose that "Amateur" is totally ignorant, from a practical point of view, of the cultivation of the soil for the different subjects he wishes to grow. Let us first look at the condition of the ground, as to its being sufficiently dry, for, if this is essential is wanting, it is vain to expect anything early, where stagnant water lodges in the soil, the sun's rays are much longer in imparting the heat necessary to promote vegetation. It is the more necessary to point to this, as, in small suburban gardens, those who construct them are often like ignorant and careless of the essentials in their formation. They are often a mixture of brick-rubbish and excavations from the foundations, in the place of the natural surface-soil which gets buried, or is sold and removed before the building is commenced. If "Amateur's" plots, which he proposes to convert into kitchen-garden ground, are unluckily in the last-named condition, little can be done without the introduction of at least 6 inches of good soil to dig into and incorporate with say 9 inches of the existing soil, which could be thoroughly mixed in the operation of digging. As all at once be apparent, the soil prepared for the seed will then be 15 inches deep. From the way "Amateur" puts his questions, I am led to suppose he is in the same position as many suburban amateurs with whom I am personally acquainted, who have spare time, and are anxious to employ in the cultivation of their garden, both for amusement and profit, yet are unacquainted with the mode of procedure—of the first operation to prepare the ground for the reception of any crop, digging, &c. By the way, I may observe that this ignorance would appear not to be confined to amateurs alone, it extends to many who call themselves gardeners, if we may judge by the way they proceed in digging, turning up each bit of soil or spadeful in great lumps, as much as 6 inches thick, throwing it over in its place without any attempt at breaking the adhesive mass, leaving the surface tolerably smooth, but the whole under-portion insufficiently pulverised for the roots of any vegetable to ramify and penetrate as they ought. In preparing the soil for the reception of seed, either by the use of the spade or the plough, the end sought is the same, namely, a thorough loosening and pulverising of the soil, as far as the nature of the land will permit, to the depth the roots of the particular crop we intend to grow will penetrate; and the more thorough the breaking up of the soil is, the more easily can the rains and the air (both so necessary to the healthy development of the crop) penetrate. This effectual pulverising of the soil has also the effect of admitting the hundreds of tender-feeding rootlets, ramifying in all directions, finding hold of every portion of the soil in their search for food. Where these conditions of the soil are absent, or only partially exist, the crop is correspondingly unfavourably placed for healthy development. We will suppose that "Amateur" intends to commence operations by digging his pieces of ground. If the land is at all heavy, he will find a steel digging fork a much better implement than the ordinary spade. Let him run over the whole of his plots, breaking the soil, as he

proceeds, into pieces not larger than a cricket-ball, bringing up the under soil and laying in its place that from the surface; carefully picking out, as he proceeds, all perennial weeds, such as Docks or Couch Grass. If the plots are level, or nearly so, it does not matter which end of the piece he commences at, but if the land slopes quickly in any direction, he should begin at the highest end, that is, throwing each spit up-hill; this is a little harder work than digging in the opposite direction down-hill, but sloping ground should always be dug twice up-hill for once down, as the soil has always a tendency to wash down-hill. Manure will be a consideration. If he can obtain it cheap, he may apply a dressing of 4 inches on the surface before he commences digging, working it regularly into the soil as he proceeds; if it is scarce and dear, he will be disposed to make as little as may be suffice; in that case he had better apply it immediately to the crops he plants as he proceeds in putting them in the ground. The next consideration will be the division of space available to the several crops to be grown, and in this he will, to some extent, be guided by individual partiality for the different vegetables usually grown. In any family, large or small, there are generally some things more esteemed than others, and even some that are never required at all. The season being so far advanced is another consideration; it is now too late to obtain early crops of many things; consequently, the varieties of some things, advisable to plant now, are somewhat different from such as should have been planted some weeks since. Another consideration for "Amateur" is, whether, with his small space, it would not be better to confine himself to a limited number of useful things, than go in for a little of everything; the former I should unhesitatingly advise, as more satisfactory; but as he expresses a wish for as great a variety as possible, I should recommend apportioning the ground in something like the following way, subject, as already hinted, to individual tastes. One-eighth of the whole space to Potatoes, which should consist altogether of early and second early kinds, such as Mona's Pride and Gloucestershire Kidney, with Early Oxford and Regents to follow in succession; these may all be planted 12 inches apart in the rows, and 18 inches betwixt row and row; plant in drills drawn out with the spade, so as to admit of the plants being covered with 4 inches of soil. If manure has not been applied at the time of digging, it should now be put in the drills with the Potato plants, it is immaterial whether it is placed over or under them, covering all up with the soil, and so proceed till all the space allotted to this vegetable is filled. Next we come to Peas, which should occupy another eighth of the available room, and may consist, for present and next month's sowing, of Yorkshire Hero, Veitch's Perfection, and Burbidge's Eclipse; these

varieties may be planted so two inches

from Pea to Pea, in rows 4 feet apart, making a second sowing the first week in May, and a third a fortnight later. The drills in which the Peas are sown should be made 3 inches deep. Broad Beans, French Beans, and Scarlet Runners should have another eighth of the space. Broad Beans—one sowing of Early Long Pod is all I should recommend this season. Plant 2 inches deep, 3 inches apart in the row, with 2 feet betwixt the rows. French Beans, Negro and Paris Red Flageolet, planted 6 inches asunder, and 2 feet between the rows. The Runners should not be planted nearer any other crop than 4 feet, nor less than 5 feet from row to row, with 9 inches of space in the row. Onions, Carrots, and Turnips should have another eighth of the ground equally divided between them. It is too late for a heavy crop of Onions; Danvers' Yellow will be the best for sowing now. Horn Carrot and Red-top American Stone Turnip: these may all be sown in shallow drills, 12 inches apart, covering the seed with half an inch of soil. The Onions and Carrots should ultimately be thinned to 6 inches apart, the Turnips to a foot; the seed should be sown four or five times thicker than this, so as to admit of failures in coming up. Cauliflowers and Cabbages should have another eighth, giving one-third of this space to the Cauliflowers and the rest to the Cabbages. Early London Cauliflowers, or Walcheren and Wheeler's Cocanut, or Early York Cabbage. The Cauliflowers, planted 18 inches apart in

the rows, with 2 feet betwixt each row; either of these Cabbages 15 inches asunder each way. To Celery and Beet, give another eighth of the space, one-fourth of this to the Beet, the remaining portion to the Celery. Beet, Barrett's or Dell's Crimson, sow in rows, 15 inches betwixt the rows, thinned out to a foot apart. Plant the Celery in well-manured trenches, 18 inches wide, the plants 9 inches asunder, allowing 3 feet between each trench. Lettuce, Leeks, Spinach, and Vegetable Marrows should have apportioned another eighth; the Lettuce and Spinach to be sown in rows 18 inches apart, the former well-manured, and thinned out to a foot asunder in the rows. Lettuce, Wheeler's Tom Thumb for early and late sowing; Paris Cos for early, and Victoria for summer and autumn supply. It is much better to sow these where they are to be grown, than to transplant, as they are not so liable to run to seed. The Leeks should be sown on a couple of square yards of ground, and afterwards transplanted in rows a foot apart, 9 inches between the plants in the rows. The Vegetable Marrow should be sown on a raised bed, under a hand or bell-glass, about the middle of May, and gradually inured to the open air, receiving plenty of water in dry weather. We now come to the remaining eighth of our space; this will require dividing for many things, amongst which should be found room for a few roots of Rhubarb, planted 3 feet apart each way. A small bed of Parsley, Mint, Thyme, Marjoram, and other herbs, and a square yard or two each should be allotted in which to sow Brussels Sprouts, Scrymger's Giant, Grange's Early White, Snow's Winter White, and Williams's Alexandra Broccolies, Savoy Cabbages, Coleworts, and Green Kale. These will come in for transplanting on the ground as it is cleared of Potatoes, Peas, Lettuce, Spinach, &c. In this arrangement I have not included either Asparagus or Seakale, as, with the first in a garden of the size under consideration, I should not advise its culture, and roots for forcing of the latter can always be bought for a price that renders it unadvisable to occupy space with it when the room is so limited. The system should be to get in a succession crop for the winter as soon as the ground can be cleared from the spring and summer occupants; in this, not a day should be lost after any crop is exhausted, more especially as the autumn approaches, for then any delay gives an insufficiency of time for the growth of these winter vegetables. This practice is necessary to make the most out of a given space, but it has a corresponding tendency to exhaust the soil. This must be met by liberal dressings of manure; four or five tons of good manure per year will not be too much. "Amateur" should also carefully preserve all his vegetable refuse; this should be kept in one corner of his garden, and all Potato tops, Pea haulm, Cabbage leaves, &c., should, as they are removed, be collected here; when rotten, a few hundredweights of lime should be mixed each year with this refuse-heap before it is spread over the ground previous to digging in; the lime will destroy slugs and their eggs, and will also act beneficially as a fertiliser. If the land is poor, a fourth of a cwt. of guano, will assist the crops much; this should be mixed with five or six times its bulk of fine ashes, or, still better, good loam, if it can be had. This should be sown broadcast over the ground, in showery weather, either before or after the ground is cropped, but with good guano, it is necessary to be cautious that too much does not come in absolute contact with any growing vegetable or it will destroy it. To those unaccustomed to high-class vegetable culture, this manuring may be considered extravagant, and not likely to pay, but it must be borne in mind that there is nothing we have dealings with that is so honest as land, and whatever we put into it, if judiciously applied, and not excessive, it is sure to give us a return with interest. The quantity of manure the market-gardeners apply would astonish anyone who has not seen it, and they make it pay or they would not do it. In breaking up and trenching kitchen-garden ground for the first time, I have dug in 150 tons to the acre; good land so treated never forgets such a dressing as this. I have recommended all to be sown in rows, which gives every facility for the use of the hoe; this implement can scarcely be used too much amongst all growing crops, providing the roots are not absolutely disturbed; it destroys weeds and slugs, both of which abound in badly managed gardens; it leaves the ground in the best condition for the absorption of rain, at the same time checking

excessive evaporation; it does not leave the surface so smooth and neat to the eye as the rake, but it is vastly preferable. already said, the season for sowing many things is far advanced, and not a day should be lost in preparing the ground, sowing such things as advised to be got in without delay.]

WORK FOR THE WEEK.

Flower Garden.

BEDDING plants should now be increased in every possible way. Brisk bottom-heat, drip-proof pits or frames, clean sharp sand, and able soil, plenty of space and plants to procure cuttings from, are requisite conditions for the purpose. Verbenas, Heliotropes, Agrostis, Lobelias, dwarf Tropæolums, Pelargoniums, Chrysanthemums, Sensation and the green-leaved summer-flowering kinds, Coleus, Iresines, Alternantheras, Gazanias, &c., strike by means of cuttings in a few days, and may be potted singly into thumb-pots, when their roots are more than an inch long. If these pots are plunged in heat, well shaded and kept moist, they never exhibit a check, but grow apace, and in a few days afford young tops for cuttings. Then side shoots for the same purpose; after that, give them another shift into sixty-sized pots. If pots are scarce, all the strongest plants after being well hardened off, may be planted out next month in frames, kept close for a few days. Coleuses, Alternantheras, Iresines, being rather tender, should be kept in pots until they are planted out. Sub-tropical plants, such as Solanums, Abutilons, Wigandias, Ferdinandias, &c., should be stripped of what cuttings may be on them every week. Maize, Castor-oil plants, Solanums, &c., should be raised from seed, and the seedlings should not be allowed to get root-bound, otherwise a stunted growth will be the result; they ought, therefore, to be pricked off, as they germinate, into small pots, and be shifted from them into larger ones. Dandelion roots are now yielding plenty of cuttings, which should be taken when fit for separation, struck in heat, and treated like other strong-growing half-tender plants. Canna roots may be divided, potted singly, and grown in a stove temperature for a short time. Some Gladiolus roots for early flowering. Evergreen trees and shrubs and deciduous trees and shrubs may yet be safely transplanted. Pruning of the latter, as well as of Evergreens, should be finished. Shrubbery borders should be lightly pointed over, taking care not to injure the roots in the operation, or to disturb any bulbous plants that may be growing amongst the shrubs. Isolated specimens of newly-planted trees, especially if large, are much benefited by a few shrubs being planted around them for a year or two, to act as protection from winds, frost, and drought; after they get established the nurses may be removed. Roses of all kinds should now be pruned, and those on pillars or walls thinned and fastened in. Prune, if necessary, Ivies on walls, and fasten any in danger of falling from them. Uncover Myrtles, Magnolias, Fremontias, Stauntonias, Clematises, and other half-hardy plants on walls, and otherwise get them in order for the summer.

Greenhouse and Stove Plants.

All hard-wooded plants, which it is necessary to pot during the spring, ought to receive that attention by the middle of the month. If cold cutting winds accompany bright weather, do not give them side air near where newly-potted plants are placed, but let the lights be opened. Shade and sprinkle water about the paths, upon the stages where the plants are placed. Let all plants as they are potted receive what tying they require to put them in proper shape, especially young growing stock. Any omission in this matter is frequently fatal to symmetrical appearance; as the plants get older the young wood becomes too stiff to bend. If mildew happens to exist on the ripe wood of last year, it will most likely attack the young growth as soon as the plants begin to move. This applies to such plants as *Boronia pinnata*, *Hedera tulipifera*, and *Lespedeza bicolor*. If such should occur, dust with sulphur at intervals. Azaleas that have been much affected with thrips last summer will be much benefited by a good washing with tobacco-water now. The eggs that were deposited in autumn will soon come to life with increased temperature. To such stove plants as are in active growth give water freely both at root and overhead, and keep the atmosphere moist by frequent sprinklings on all available surfaces. A little shade, when necessary, prevents scorching. Air should be given in the morning, and the house should be shut up early. Pot Gesneras, Gloxinias, Achimenes, and Caladiums, and place them in heat to succeed those previously started.

Hardy Fruit Garden.

Outdoor fruit trees, as a rule with, perhaps, the exception of Apricots, promise to produce heavy crops. Plums are laden

flowers, and Cherries have set blossom buds in abundance; Pear-trees, too, are most satisfactory. Finish grafting, more especially that of stone fruits, as speedily now as possible. If not already done, mulch between the rows of Strawberries with litter, the nutrient from which will be washed down to the roots by successive rains, leaving the surface clean for the fruit to rest on when ripening. See that Raspberry bushes are securely fastened to their supports; in most cases they are grown erect and tied to wooden stakes, but in others one-half of the rods from a stool is loosely plaited and brought to meet a similar number of canes from the next, thus forming a series of arches, whilst, in other instances, the rods are cut about 3 feet in length, and are tied together without a stake; in some other cases, too, they are tied to wires or trellises.

Kitchen Garden.

Cabbages and Cauliflowers have started actively into growth; the must, therefore, be kept at work amongst them, as nothing is more productive of good to vegetables than a clean and frequently-sirred surface. Make a general sowing of Cauliflower, and prick off into a warm corner or border those sown last month, as soon as they are fit to handle; and, in the event of cold or wet weather occurring, hand-lights, frame sashes, or hoops and mats may be employed for their protection. Sow some of the early kinds of Broccoli, and, in cold localities, also late sorts. Of the fine curled Italian Endive, sow some seeds in a brisk temperature for early use; but if not sown in a strong heat, the plants are apt to run prematurely to seed. The main crop of Beet may now be sown; but in warm counties, towards the end of the month will be soon enough. It likes an open situation and trenched ground that has been manured for the previous crop. Thin Parsnips when they appear, but not finally; some growers prefer sowing early in this month, but, even about London, Parsnips are sown at the same time as the spring Onions, for they take a long time to germinate and they are not liable to "run." Sow Chicory thinly in rows, about 6 inches apart, for winter forcing. As soon as Globe Artichokes have made growths about 9 inches long, slip them all off except the three strongest, which should be retained for the summer's produce. The best of the slips should be chosen for a new plantation. Cut the peel attached to each smoothly, and then plant them 8 or 9 inches apart in clumps of three, each clump about 2 feet apart, in rows 3 feet asunder, in a deep rich sandy loam, and in an open situation. Sow some summer Savoy in a warm border, and increase the stock of the winter kind, either in the same way, or by dividing the old plants. Fresh Tarragon plantations may be obtained by planting rooted slips from the sides of the old roots; Tansy may be increased by division of the roots, and Sorrel by sowing or dividing the roots; Elm, Burnet, Thyme, and Mint may be propagated by dividing the roots; and Hyssop, Fennel, Sage, Rosemary, Pennyroyal, and Lavender by slips, which, if rooted, are so much the better; while Chervil, Clary, Sorrel, Samphire, Purslane, and Borage require to be raised by means of seeds. Basil and Knotted Marjoram are best raised in a gently-heated frame, and well hardened off before being finally transplanted. Preserve a piece of a warm border for French Beans; but it is rather too early to sow them yet. Before sowing, open the drills in the morning, if fine, and sow the seeds in the afternoon. Sow Cardoons where they are to remain, in lines 4 feet apart, so that three seeds may be in a clump, and the clumps 2 feet asunder. In the northern counties, Gherkins may be sown in gently-heated frames; but, in warm and southern localities, May is soon enough for sowing; whilst, if a well-sheltered warm border be selected, they may be sown in lines, 4 or 5 feet apart, out of doors in the latter half of May, when they yield their crop at the end of July and in August. Keep a succession of Peas and Beans, and attend to timely staking. Occasional sowings of small salading must be regularly attended to, and Lettuces transplanted, sown, and thinned. Sow Turnips as required; and, in case of the coming summer being hot and dry, a fall sowing of early white Vienna Kohl Rabi may be found useful.

Plant Origin of Japan Lacquer.—It has been generally supposed, says the *Scientific American*, that the beauty of Japan lacquer-work was due to ingredients derived from unknown plants, and that the secret was confined to the Oriental workmen. Recently, however, in Holland, objects of art have been produced, lacquered and covered with mother-of-pearl in pieces, facsimiles of those made in Japan. The lacquer used is prepared from the hardest varieties of copal, principally that of Zanzibar, which is coloured black with Indian ink. The articles are covered with several layers of this substance, upon which, while still wet, or rather pasty, the mother-of-pearl is inlaid. Drying in a furnace follows, another coat of lacquer is applied, then more drying, and smoothing with pounce. The operations are repeated until the surfaces are perfectly united and smooth, when a final polish is given with tripoli.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

APRIL 15.

Rhododendrons.—These, though limited in number, were shown in excellent condition on this occasion by Messrs. Lane, of Berkhamstead, who had a nice group of plants and some splendid trusses of cut flowers. Among the varieties, we noted *R. hybridum roseum*, a richly-coloured crisped variety, with fine wax-like foliage; *Verschaffeltii*, a delicate lilac, the upper petal spotted with maroon; *Queen of the West*, a bright rosy-lilac, each petal being beautifully crisped; *Limbatum*, a very distinct variety, with white flowers margined with bright rose; *Auguste Van Geert* is a most profuse bloomer, the flowers being of a deep purple-lilac, and the foliage of good substance. The best white in this group was *Bodaertianum*; this is a waxy white variety, with the faintest trace of blush in the youngest flowers.

Cinerarias.—With these, Mr. J. Standish, Nurseries, Ascot, was first; a second prize being awarded to Messrs. Dobson, Woodlands Nursery, Isleworth. Both collections contained compact and well-grown plants, the colours being bright and distinct. In the Amateurs' Class, Mr. James, gardener to W. F. Watson, Esq., Redlees, Isleworth, was deservedly first, with very nice plants, dwarf and well bloomed. Mr. R. Warcham, gardener to J. Mitchell, Esq., Coppins, Iver, Bucks, was second, with larger plants, the strain being better than in the last group, but the plants were not so evenly bloomed.

Azaleas.—Messrs. Lane staged nine well-bloomed plants, to which the first prize was awarded. In this group, the most notable were *Comet*, a scarlet variety shot with purple; *Flag of Truce*, a very beautiful semi-double white, the flowers being very pure; *Roi d'Holland*, a brilliant scarlet; *Roi Leopold*, deep rose, shaded vermilion, and *Gloire de Belgique*, a fine white, inclined to sport into rose. The two best scarlets in this collection were *Vesuvius* and *Stella*, both very vividly coloured and attractive. The second award went to Mr. Charles Turner, of Slough, whose plants were much smaller but still well-bloomed, and well suited for ordinary purposes of decoration. The most notable were—*Apolla*, a fine white, inclined to break; *Erbprinz Ludwig*, a semi-double of the brightest rosy-lilac; *Mrs. Turner*, salmon, edged with white and beautifully spotted. The most attractive plant in the whole group, however, was *Charles de Buck*, an immense flowered variety of the brightest rosy-crimson imaginable. In the class for plants in 12-inch pots, Mr. G. Wheeler was first, with very compact specimens, including *Model*, a fine rosy-lilac; *Chelsonii*, a good old scarlet variety, with crisped petals; *Stella*, one of the best of the scarlets; *Duc de Nassau*, a semi-double lilac, and *Magnificans*, pure white. The second award in this class was given to Mr. R. Marcham, who had well-bloomed plants, the most notable being a plant of *Criterion*, a rosy variety, edged with white, the upper petal being spotted with deep rosy-crimson.

Clematis.—Messrs. Jackman, of Woking, staged about thirty plants of their new hybrid Clematises, which we admire the more, the more we see of them, so deserving are they of general culture, either in pots or planted out. Among those staged on this occasion, we noted the following as distinct and good:—*C. Baroness Burdett Coutts*, a large-flowered variety, of a delicate rosy-lilac; *Lady Stratford de Ratcliffe*, a beautiful lavender-blue, large and fine; the *Queen*, a delicate lilac; and *Vesta*, an eight or ten-petalled flower, of remarkably good form and pearly whiteness, with purple stamens. The majority of the plants were 18 inches to 2 feet high, and as much in diameter, bearing from thirty to sixty flowers each.

Roses in Pots.—Messrs. Veitch & Sons exhibited a very fine collection of fresh healthy plants, well bloomed. The best in this group were *Charles Lawson*, deep rose, *General Jacqueminot*, a well-known old crimson, and *Marguerite de St. Amand*, a silvery-rose or pale lilac. The best Teas were *Madame Willermoz*, one of the best whites, and *Madame de St. Joseph*, a fine salmon-flesh, fine in the bud, and a fine variety for cutting for bouquets. Mr. W. Paul, of Waltham Cross, had a larger collection of smaller specimens. Among the Tea-scented varieties we noted *Marie Van Houtte*, a delicate sulphur, *Souvenir de Paul Neron*, a fine white variety tinted with salmon or flesh colour. The best in this group, however, was a plant of *Catherine Mermet*, a really superb Rose of the most delicate flesh colour. Two good stands of cut Roses came from Mr. J. Walker, Thame, Oxford, containing fine blooms of *Maréchal Niel* and *Gloire de Dijon*, two of the best Teas. Mr. G. Paul, Cheshunt, showed cut flowers of *Cheshunt Hybrid* and *Madame Lacharme* Roses, the blooms of the latter being the best we have yet seen, and of remarkably good form, round and full.

Orchids.—Mr. Denning, gardener to Lord Londesborough, furnished half-a-dozen well-bloomed plants, including the following: *Dendrobium Jenkinsii*, a pretty scendant species with orange flowers; *D. fimbriatum oculatum*, with at least thirty spikes; *Cattleya Skinnerii*, a very good variety, with rich lilac-purple flowers, the throat of the lip being pure white; and *Cattleya citrina*, a fine specimen, on a block, bearing eleven wax-like lemon-tinted flowers, most deliciously scented. The most notable plants in this group were fine specimens of *Arpophyllum giganteum*, bearing fifteen fine spikes of shell-like flowers, of a bright purple colour; and a plant of *Vanda cærulescens* bearing three fine spikes, on the largest of which we counted twenty-three flowers of a deep cerulean blue, with a deep tinted lip. Mr. G. Wheeler was second with half-a-dozen well bloomed plants. In the Nurserymen's Class, Mr. B. S. Williams, of Holloway, staged six fine plants, including one of the finest plants of *D. nobile* we have ever seen, and a splendid plant of *D. Infundibulum*, a fine variety, with a Roman red stain on the lip in place of the golden-

yellow blotch usual to this species. In this group there was a magnificent specimen of *Aërides Fieldingii*, with at least eight fine drooping spikes of deep rosy-lilac spotted flowers, and a fresh and healthy specimen of the purple spotted variety of *Cymbidium eburneum*. In the Miscellaneous groups, Mr. Denning had a rare and valuable collection, including the yellow-flowered *Dendrobium senile*, a dwarf species, the pseudo-bulbs being densely covered with long white hairs; two splendid varieties of *Masdevallia Harryana*, and one of *M. Lindenii*, with its glowing lilac-purple flowers; and a good plant of the rare old rosy *Odontoglossum* (*O. roseum*). Messrs. Veitch & Sons had a splendid group, including many of the latest novelties already referred to in our columns. On this occasion we noted *Odontoglossum vexillarium*, with its rich rosy flowers; *O. novium*, with white purple-spotted flowers; *O. Alexandrae*, a dense flower, very richly coloured; and the rare little Japanese *Aërides* (*A. japonica*).

Miscellaneous.—Messrs. Cutbush staged some nice plants of *Cinerarias*, well-bloomed, and a few plants of the beautiful old double-yellow Wallflower, so useful for cutting. Mr. Marchant, gardener to J. Mitchell, Esq., Coppins, Iwer, Bucks, had half-a-dozen well-grown rosy and white Chinese *Primulas*, of a good strain. Mr. W. Bull staged a noble group of *Cycads*, to which an extra prize was awarded. We allude to these beautiful plants in another column. Messrs. Veitch & Sons contributed a fine group of early-flowering decorative plants, including greenhouse *Rhododendrons*, *Azaleas*, *Libonias*, *Epacris*, and *Clematis*. In this group we noted a fine pan of the pure white *Primula nivea*, and another of the rosy-flowered *Hydrangea*, *Stellata* fl. pl., a most useful decorative plant: two fine plants of *Rhododendron*, Countess of Raddington, and Princess Alice, were profusely bloomed. These, together with a profuse sprinkling of the choicest *Orchids* made up a most attractive group. A fine bank of *Cyclamens* came from Mr. James, and these obtained an extra prize. Messrs. J. Standish & Co. sent a fine assortment of decorative and early-blooming plants for cut-flowers, including the white forcing *Pink Lady Blanche*, *Abutilon* *Boule de Neige*, *Azalea Juliette*, a rich rosy semi-double variety, and *A. Sigismund Rucker*, a variety tinted like *Criterion*, but a much finer flower; also the hardy *A. mollis*, with orange-red flowers; and *A. linearis*, another hardy species with very narrow rosy petals, $2\frac{1}{2}$ inches in length, and only a line or two broad. These, together with the feathery-leaved *Acers* and *Cinerarias*, made up a fine bank. Messrs. Barr & Sugden staged a fine group of early flowering *Narcissus*, containing many rare and beautiful flowers; this collection was much admired. Lord Londesborough sent a fine group of *Orchids*, containing some rare plants previously alluded to. Mr. B. S. Williams staged a nice assortment of *Palms*, *Ferns*, *Orchids*, and *Cycads*, and a specimen of *Primula cortusoides amœna alba*, a pure white variety, that will be invaluable as a pot plant when plentiful; a plant of *Sarracenia Drummondii* bore four of its large lurid purple flowers, and a plant of the ivory white *Chysis bractescens* was well flowered. Messrs. Veitch & Sons staged an attractive group of cut-leaved *Acers*, some of which were very elegant; in colour, they vary from fresh green to the deepest bronzy-purple; even if these do not prove sufficiently hardy for outdoor culture they will be invaluable additions to the greenhouse or cool-conservatory. Herbaceous plants and *Alpines*—Mr. Parker, of the Exotic Nursery, Tooting, staged about forty specimens of spring-blooming hardy flowers in pots, and these were fresh, well bloomed, and much admired. Among them we may notice *Epimedium roseum*, with heart-shaped foliage and deep rosy flowers; the beautiful *Primula nivea*; *Iris nudicaulis*, a deep rich purple; *I. pumila*, one of the best known and most beautiful of all the dwarf kinds. The pot of *Triteleia* (*Milla*) *uniflora* was the finest we have ever seen, being one dense mass of foliage studded thickly with hundreds of its white star-like flowers. Its variety *lilacina* has blue flowers, and is sometimes known in gardens as *Leucocoryne affrica*. Two pots of *Scilla campanulata* and *S. nutans rosea* were well bloomed and very attractive, as also was a fine specimen of the golden-rayed *Doronicum austriacum*. A pot of *Bellis aucubaeifolia*, with its golden-marbled foliage and crimson flowers, contrasted well with a beautiful mass of the blue-flowered *Aubrietia purpurea elegans*, and this contrast was again further enhanced by a fine golden mass of *Primula elatior*, "Golden Plover." Mr. R. Dean, of Ealing, staged about two dozen smaller plants well flowered. Among them we noticed a fine variety of the double white *Daisy*, a first-rate plant for spring bedding; *Myosotis dissitiflora*, a perfect mass of deep blue flowers; also, the pink-flowered variety of *Bellis aucubaeifolia*, and several pots of the old double lilac and yellow *Primroses*. Tom Thumb bedding *Pansy*—"Yellow Boy"—is dwarf and compact, with richly-coloured flat flowers of a deep golden-yellow, and, if as well adapted for bedding as it evidently is for pots, it will prove a most valuable acquisition.

Fruit.—The show of fruit was limited in quantity, but in quality excellent. In the class for *Grapes*, Mr. W. Wildsmith, gardener to Viscount Eversley, Hockfield Place, Winchfield, was first, with two superb bunches of *Lady Downes* cut from the Vine on the 4th of February last and preserved in water. Second, Mr. H. Harris, gardener to Lord Ashby, Naseby Woolleys, Rugby, who had two fine bunches of *Black Hamburgh*, of this year's growth. The competition here lay between cultivation and preservation, and the award went to the latter. The first prize for white *Grapes* was also taken by Mr. Harris with nice clusters of *Sweetwater*. *Strawberries* were very fine. The first prize being awarded to Mr. Sage, Ashridge Gardens, Great Berkhamstead, who had a very fine basket of Keen's Seedlings, very tastefully set up in a round basket. Second, Mr. D. Pizzey, gardener to Sir E. Perry, Fulmer, Slough. *Easter Beurré* and *Ne Plus Meuris* *Pears* were shown by Mr. Jones, of Frogmore, who also set up a fine group of *Apples*, to which an extra prize was awarded. Two fine smooth *Cayenne Peas* also came from the Royal

Gardens, Frogmore, and these were splendid examples of good culture. Mr. W. Gardiner, gardener to E. P. Shirley, Esq., Stratford-upon-Avon, also staged a nice collection of *Apples*, containing about two dozen varieties, all in a remarkable state of preservation, though scarcely as good as those from Frogmore. *Cucumbers* came from Mr. J. D. Pizzey, gardener at Loxford Hall, Ilford, and from Mr. D. Pizzey, of Slough. Both were awarded equal first prizes. *Peas* were very good, the best exhibited being Watts's *Excelsior*, but, as these were not for competition the first award went to Mr. E. Clarke, gardener to J. R. Hall, Esq., Sutton, Surrey, who had some good *Walcheren*; second, to Mr. Norton of Coombe Bank, Kingston-on-Thames; and third to Mr. C. C. Gardner to the South London District Schools, Sutton, Surrey.

First-class Certificates were awarded to the following new plants, viz.:—

Oncidium fuscum (Veitch). A form of *Reichenbach's* *Milomina* *Wiesii*, having rosy-tinted flowers in place of the yellow and brown ones of normal type. It is even more ornamental as a garden plant, and well worth culture.

Cattleya gigas (Veitch) is one of the finest of all *Cattleyas*, and will be sought after by growers. It has large rosy-lilac flowers, the broad lip being mottled with deep violet-purple.

Ficus Parvelli (Veitch) is one of the finest white-variegated plants we have ever seen. Its leaves are as large as those of *Ficus elastica*; but are thinner in texture, and coarsely serrate along their margins. They are light green, irregularly blotched profusely with creamy-white and dark green. If the pace of free growth, as its appearance indicates, it will form one of the finest variegated decorative plants introduced of late years.

Clematis Lord Gifford (Noble) is a beautiful purple-lilac variety, and a vigorous grower.

Clematis Marquis of Salisbury (Jackman). This is a most vivid purple variety, and evidently a most profuse bloomer.

Clematis Countess of Lovelace (Jackman) is a light bluish-lilac form, and a fresh vigorous foliage.

Ceterach aureum (R. S. Williams). A strong-growing tropical form of common *Ceterach officinarum*, having fronds 12 to 15 inches long, and 3 inches broad. The fronds are of a deep green colour, and are densely covered behind with silvery scales, which turn brown as the fronds develop themselves. It is a distinct plant, and one well worth growing.

BOTANICAL SOCIETY OF EDINBURGH.

APRIL 9TH.

The president in the chair. Mr. Sadler read a series of notes by J. Wright, Halston Hall, on *Eucalyptus globulus*. This tree, which is native of Australia, grows very rapidly—as much as 6 feet in a year—and has been introduced, and was now largely grown in Algeria, Spain, the south of France. Its medicinal properties had been attracting attention in France, and the alleged cures by it had been making a great sensation there. It was stated to have been employed with much effect in cases of asthma, low fever, rheumatism, and it had been employed instead of gum. During the Franco-Prussian war, the leaves of the tree had been employed effectively in cases of lung gangrene. Mrs. Wright was assured that it would be useful in cholera and epilepsy. The president said that this seemed to be one of the articles sent to Europe from all parts of the world, which were to infallible remedies for various diseases. It was a most remarkable fact that these so-called remedies were to be applied to the most intractable inconsistent diseases. This one was to cure asthma, low fever, hospital gangrene, epilepsy, and cancer; to make us perfectly hydrophobic and the bites of venomous snakes would only be required to be added to the list. He only wished they had sufficient specimens to make a trial of its curative powers. Dr. Cleghorn said that the tree had been introduced into India, and that in fifteen years it stood 15 feet high and was then used for building purposes. Mr. Etheridge said he had seen a *Eucalyptus globulus* tree in Australia, which, when cut, measured 5½ feet. A red gum exuded from it, the wood was of a red colour, and when thrown into water it sank. Throughout the Australian colonies the tree was believed to be an infallible cure for rheumatism. Mr. James McNab, curator of the Royal Botanic Garden, read his monthly report on open-air vegetation at the gardens. The usual mildness of the winter and spring had, he said, been instrumental in bringing forward forest vegetation in the neighbourhood of Edinburgh to an extent he had never before observed at the same date. At present many forest and ornamental trees were in flower, such as the Norway Spruce, various species of *Fir*, *Willow*, *Alder*, *Birch*, *Fraxinus*, particularly the common *Gum*, which was quite white-blossomed. A given hour pervaded a large proportion of forest and ornamental trees, such as the Horse Chestnut, *Fir*, *Larch*, *White Birch*, *Salix*, *Poplar*, and many varieties of *Thorn*. The *Thorns* were in full leaf, and he had seen one with the flowers expanded. He had never before observed a *Thorn* come into flower so early. The temperature had been during the past month only 1° times at or below the freezing point viz., on the 21st and 26th, 3rd, 4th, and 5th April. It was remarkable that there had been an almost absence of easterly winds, which often proved so destructive to blossoms of fruit trees, while strong west and north-west winds prevailed. He showed the flowers of 181 species of plants, and shrubs picked in the open air on 4th April—an unusual number at this particular season. The ground temperature had also been unusually high. A tortoise, which had been in the B. Garden for fifty years, and which usually buried itself in the earth at the beginning of December, and did not appear again till the second of April, had this year emerged on the 12th March—a circumstance unprecedented.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

HYDE PARK; ITS HYACINTHS AND TULIPS.

By SOEL HUMPHREYS.

THERE is much to admire as well as much to criticise in the management of this, the largest of our metropolitan parks. It is, doubtless, to be regretted that some of the fine old trees are fast disappearing—some from their venerable age, and others, such as those which were enclosed within the great glass dome of the first Crystal Palace, from causes and exigencies which might, perhaps, have been avoided. Yet, it is a consolation to find that young trees are being judiciously planted to replace the gaps that London smoke, combined with accidents, and, in some cases, want of wise and timely supervision, have but too fatally made. It is doubtful, however, whether the young trees will ever attain the size and magnificence of the ancient plants, whose venerable trunks are, year by year, disappearing. Some of the younger trees, now twenty or thirty years old, have grown but slowly. They are not absolutely stunted, but they are, undoubtedly, small for their age; and their general aspect does not display the vigorous character one would wish to see. This is, no doubt, caused by the gradual, but persistent, leaning-in to which they are compelled to submit by their deadly enemies, the army of smoke-exhaling chimneys. That is a difficulty that park-management will have to contend with, in an increasing degree, year after year; but it is one which yet leaves us many rays of hope. The smoke-plague may, some day, be abated by the enforced use of smoke-consuming grates; but, even if the proverbial slow working of our legislative machinery should be two many centuries in effecting this reform, there is no occasion for absolute despair; for open spaces in London, long since closed in by miles upon miles of dense masses of building, have yet some nice trees remaining. Lincoln's Inn Fields may still boast of trees and shrubs that bravely defy the smoke; and so may Russell Square, Brunswick Square, Grosvenor Square, and other spaces that are, beyond dispute, in the very heart of London. The smoke does not kill our tree vegetation outright; but it blackens it, disagrees with it, and checks its growth. Yet we shall still have Oriental Planes and other town-thriving plants in spite of it, even in the very core of our big city. So it will be with Hyde Park; and, where tree growth fails, we may set out with flowers; and this reflection leads us to the magnificent show of floral splendour that has been made along the whole eastern side of the Park, facing Park Lane, for the last few years, but more especially during the present season. The Hyacinth show has been truly superb. It is now considerably past its best, on a close inspection, but at a little distance the long succession of masses of splendid colour seems to glow in the bright verdure of the early spring turf, like giant gems set in a vast gypsy ring of some precious kind of green-coloured gold. These densely-filled beds of flowers succeed each other, varying distinctly in colour, for nearly the whole length of Park Lane, till they blend into a distant rainbow horizon of many hues, mingling harmoniously with each other. Those masses, which are formed of a superb deep purple kind, verging to black, produce a magnificent effect when followed by a contrasting mass of white, which, in its turn, is succeeded by one of deep rose-colour; and then comes the purple-black again, and then one of soft corulean-grey, and then mauve, and then deep red, and ochreous yellow, and then white again, till the eye can scarcely distinguish, in the distance, where or how the still succeeding masses blend into each other. The almost invariably fine and perfect character of each spike of flower, of all the varieties, does infinite credit to those skilful Dutch growers of the bulbs, whose fields of Hyacinths, acres in extent, scent the air, from Haarlem to Leyden, in the early days of April. It is indeed wonderful how such uniform perfection is achieved, when the vast numbers produced are taken into consideration; for, in a single bed of the Hyde Park display, I

counted 300 flowers, all equally good, without speck or blemish. The Tulip display is equally fine, and has the advantage of being still in full perfection—indeed, scarcely at its best; so that those who lose no time in hastening to see it will enjoy the sight of these gorgeous Tulip-beds in all their perfection. Some of the masses are, indeed, still in green bud, and this is a defect of management; for, if the kinds in question are rather later-flowering sorts, they might be planted earlier, to give them a little start. This, however, is a very small matter to notice, when the general display is so truly gorgeous. Many admirers were lingering over the display last Saturday with evident interest; taking down the names of the most striking kinds, with the intention, as was plain enough, of turning their newly acquired knowledge to account in the selections for their own private Tulip-beds next season. Among the kinds producing the most decided effect were the pure whites, the pure canary-yellows, the Gloria Solis, and the Kaiser Kroom, which, being translated from the Dutch, may mean the Chrome Emperor; for the lower part of the flower is of a bright blazing orange-scarlet, and the upper part a full and dazzling yellow chrome. These are varied by masses of a double kind, of a rich bluish-magenta colour, succeeded by double whites, rich crimsons, and many others; but some of the old favourite kinds, the whites, carnation-striped with crimson, and the yellows, tiger-striped with black or purple, are not represented. There seemed to be a good deal of disappointment among the visitors on account of the Hyacinths being without names, which is certainly an omission, seeing how eagerly those of the Tulips were "booked" by the spectators. The display of Crocuses, of the best kinds, which formed an edging to the Hyacinth and Tulip beds, while they were still only in bud and promise, are quite over; but their green foliage still forms a pretty and appropriate bordering. While on the subject of the general "keeping" of Hyde Park, there is one matter which requires notice—it is that the turf (in the portions of the park devoted to flower-gardening) is in many places defective; for, under the drip of large trees, or from other causes, there are large and very ugly bare patches, which ought to be repaired with fresh turf each season. No such blemishes could be found in the Bois de Boulogne, or even in the pretty little park at Brussels; and in the chief pleasure-ground of the richest metropolis in the world, they certainly ought not to exist. No time ought to be lost in attending to these blemishes in the turf, which occur in many other parts, as well as those devoted to floral displays. It is not the battering of the turf for a considerable distance on either side of the pathways which leads across the park, from the Bayswater Road to Kensington, that is alluded to. These pathways are generally protected as much as possible by light iron fenceings, which would fulfil their object, but that certain sections of the public are so jealous of their liberties—even the liberty to do a little bit of mischief, if it so pleased them—that the very fences set up to protect the turf, though for their own enjoyment, are looked at askance, and no opportunity of tramping over it in spite of them is ever let slip. It is the more essential to keep the whole of the turf as perfect as possible just now, because the verdure of the trees, under the influence of the genial warmth of the last few days, is becoming bright and May-like, even before its time, and it is a pity that stunted patches of browned turf should clash with the general vernal aspect which the park is daily assuming. Since Tuesday, the Lilacs in the shrubberies are recklessly bursting into bloom, utterly regardless of nipping night frosts that may yet come. The Horse Chestnuts have rapidly unfolded their big leaves, soft and tender both in hue and texture—and their spikes of green buds are shooting upward and from the end of every branchlet, to make the "Hyacinth-tree" one of the spring glories within a fortnight's time if the present glowing weather continues. On the bank above the Serpentine, too, is a fine clump of Ashes, which is well worth inspection. Few have any idea of the wonderful variety which is to be found among them, both in foliage and habit. It may be stated that there has been, in the shrubberies next Bayswater Road, a good deal of random butchering (not pruning), which has so fearfully disfigured long stretches of Lilacs, Ribes, Aucubas, and other things, that they had far better be cleared away, and their present wrecks replaced by turf.

NOTES OF THE WEEK.

— WE have received from Messrs. Backhouse, of York, a fine specimen of one of the loveliest of Alpine plants, viz., *Dianthus glacialis*. This, in the sturdy dwarfness of its growth, and the singularly delicate but rich tint of its rosy-pink flowers, is a worthy rival of the now pretty well-known *Dianthus alpinus*. It is not such a large-flowering or deeply-coloured plant as the last-named species, but it possesses a charm of habit and hue peculiarly its own, and which will ever secure for it a first place in the ranks of dwarf-hardy rock-work plants.

— AT a sale of Orchids which took place at Stevens's on Wednesday last, *Masdevallia Veitchii*, "a splendid mass with sixteen breaks," fetched £10 10s.; *M. Harryana*, £3 15s.; and *M. ignea*, £5 15s. 6d.; *Cypripedium Argus*, a distinct species from the *Philippines*, so named in allusion to the numerous eye-like spots which it has upon its petals, fetched £3 10s. Altogether the sale which consisted of some 286 lots, realised about £500.

— THE Plane trees on the Thames Embankment have already put forth leaves. They were amongst the first this early season to exhibit signs of vitality, and, unless checked by some inopportune frost, they will, we believe, soon exhibit all the wealth of foliage for which Plane trees are remarkable in the summer months. Some of a larger size, close to Covent Garden, as yet show no fully-developed foliage; though, within these last few days, their buds have swelled considerably. Two Poplars, growing beside them, were in full leaf quite three weeks ago. Where early leafing is desirable, these are, therefore, useful trees to plant.

— SOME fine specimen Camellias are just now flowering most profusely in the conservatory at Chiswick House. Of these one of the most notable is a noble plant of *C. reticulata*, a well-known kind now rarely seen in even the best collections, possibly on account of the semi-double character. There is, however, an old plant of it in one of the pits at Chiswick, where it blooms most abundantly every spring. A year or two ago, branches of this Camellia, bearing flower-buds, were grafted on dwarf stocks of the common kinds, and two or three dozen of these miniature plants in flower were exhibited at South Kensington, and attracted considerable attention at the time. One of the largest specimens of *reticulata* with which we are acquainted is at Grove Bank, Kingston.

— A NEW parasite, or rather a newly-imported parasite, which is likely to prove a trial to gardeners, has appeared both in England and on the Continent. It is a fungus, which attacks Hollyhocks most destructively. It is believed to be indigenous to Chili, and its botanical name is *Puccinia Malvacearum*. It was first observed near Bordeaux in April last, and appeared in many places in England during the summer, committing so much havoc among our Hollyhocks as to render them very scarce this year. Commerce has, no doubt, been the agent by which this pest has been introduced; to it we are also indebted for the American Water Weed, and it will, probably, inflict other of the evils of distant lands yet upon us.

— THE members for Canterbury have shown their appreciation of the objects of the Canterbury Horticultural Society by presenting, for competition at the show proposed to be held in Tower House Grounds in August next, a handsome silver cup of the value of five guineas. In order that the competition for this gift may be as popular as possible, the committee have determined that the prize shall be awarded for the best general collection of fruit and vegetables, exhibited by a citizen amateur grower who does not employ the services of a gardener. If the gift is supplemented by the subscriptions of the citizens, the promoters of the show will be enabled to issue a list of prizes of a substantial character, and a really first-class exhibition will be the result.

— AT a meeting of the fellows of the Royal Horticultural Society held in January last an attempt was made by a number of fellows to have the privilege of voting by proxy, long enjoyed by lady members, extended to gentlemen. Nothing was then done, but at the annual meeting in February a similar attempt was made, and then Viscount Bury promised, on behalf of the council, to have a bye-law framed which would give the proxy vote to the fellows, and submit it for discussion at a special meeting to be subsequently summoned. At the same time the president and council reserved to themselves the right to discuss the question when it came before the special meeting. On Tuesday last the bye-law was submitted, and the president, in placing it before the fellows, said the council were, with one dissentient, unanimously opposed to the proxy principal, under which, he said, no council could work with self-respect, but they had fulfilled their promise, and now the time for discussion had arrived. Thereupon Mr. Bateman moved and Mr. Wilson seconded, the adoption of the new bye-laws. A warm discussion followed, and, eventually, on the motion of Dr. Denny, seconded by Mr. Liggins, an amendment repealing the bye-law which gave the

proxy vote to ladies was passed by a considerable majority. Hence not only was the resolution providing vote by proxy for male fellows negatived, but the privilege which has been enjoyed by lady fellows was taken away by the amendment.

— THE fruits of *Sapota Achras*, known in the West Indies as Sapodilla Plums, are now being sold on barrows in the streets of London, under the name of "*Nespras nepolica*," at the rate of eight a penny.

— TO grow the Bay tree at all in the north country is considered a triumph, and to see it in bloom a novelty, which few have witnessed. At Exmouth, however, at the present time, each branch is completely wreathed with its singular blossoms, which collectively might easily be mistaken for a bottle-brush, clothing, as they do, the branches so thickly as to make them look like those of a *Metrosideros* or *Melaleuca*.

— THE brilliant weather of the past week has invested our spring flowers with fresh brightness, and many of the beds and borders in our London parks are becoming attractive earlier than usual. At Battersea, the plants in several beds near the West Lodge, are beautifully in bloom, and a narrow border near the same spot is particularly effective, having been planted with a row of double white and double red Daisies, all finely in bloom, and edged with the Golden Pyrethrum, the whole forming quite a charming combination.

— AMONG the many additional resources of out-door recreation about to be provided at Alexandra Palace during the ensuing season none will possess greater prominence than the fine sheet of ornamental water now nearly completed. It covers some six acres, in close proximity to the palace. Much skill is shown in so arranging the plan of this lake as to conceal at any point of view its full extent, and the varied outline, islands, and buildings which adorn it render it an exceedingly ornamental, as well as attractive, feature of the grounds.

— A NOVELTY, in the way of a pot-coverer, has been invented by M. Gorse, 10, Rue Legrattier, à Paris, which may recommend itself to the notice of those who cultivate plants in rooms. It consists simply of a circular piece of zinc made to fit the top of the pot, and divided into two semi-circles, united by a hinge at one point of contact. In the centre, a space is left, which allows free passage for the stem of the plant. The utility of M. Gorse's invention seems chiefly to point to the fact that plants thus protected will require much less water than they otherwise would do, as the evaporation from the soil in the pot is very considerably diminished.

— IN answer to a question put to Lord H. Lennox, respecting the surroundings of the Bethnal Green Museum, his lordship said: "It is quite true that one of the obligations under which this Museum was, in 1868, transferred to the Government was that the vacant spaces around it should be laid out and permanently maintained by the Board of Works as a flower garden for the recreation of the people. Owing to some inadvertence, the Board of Works was not made aware of this condition until last June; and when it was, my predecessor, Mr. Ayrton, gave instructions that a sum of £700 should be inserted in the estimates of the ensuing year for the commencement of the garden. Matters stood thus when I acceded to office. But considering the uncertainty which always prevails as to the time when estimates are voted, I feared that another year might in this way be lost. So, with the sanction of the Treasury, I ordered the works to be begun. They have been begun, and will be pushed forward with the utmost energy, so that as soon as possible the people of the East-end of London will have these gardens, as is their undoubted right, finished and made available for their recreation."

— A CORRESPONDENT informs us that the rare and botanically interesting plant, *Megacarpea polyandra* (De Candolle), is again flowering at Glasnevin. The plant, which is blooming, was raised from seeds saved at Glasnevin six years ago, and this is the first year during which one of these seedlings has flowered. It therefore takes a longer time to come to maturity than most Crucifers do. In general appearance, this *Megacarpea* bears a greater resemblance to Umbellifers than it does to Crucifers, and is a good deal like the Parsnip (*Pastinaca sativa*). The flowers are produced in close corymbs, resembling umbels, and are of a greenish-yellow colour. The leaves are large, broad, and pinnatifid, quite like those of many kinds of Umbellifers, and the plant is strong and about the size of them; besides, the fruits are short, flat, and broad, more like Cremocarps than Siliques or Silicles. The most remarkable peculiarity is, however, in the Androecium, which is nearly allied to that of Papaveraceæ, each flower having constantly from twelve to sixteen stamens. It is a native of the higher regions of the Himalayan Mountains, and, to cultivate it successfully, it requires to be grown on a cool moist border, which is shaded from the mid-day sun, but otherwise, it is quite hardy for out-door culture in this country.

THE FLOWER GARDEN.

SNOWDROPS *AU NATUREL*.

SNOWDROPS, as the very first of the flowers that greet the new year, possess a charm peculiarly their own. The milk-white flower, as its Greek name implies, often finds its way through long-lying frozen snow; and when its pretty oval bud, like the egg of the future flower, first pierces the icy covering, its daring pertinacity to arise from its cold bed and bloom, even in the very earliest dawn of spring, takes us by surprise. The first sight of it is, undoubtedly, pleasure-giving in a high degree. Its early appearance, even within the prosaic and as yet desolate lines of the flower-border, is always hailed as that of the flower of promise, the *avant courier* of all the bright blossoms that are to come. But while its simple beauty is always attractive, under any circumstances, it becomes much

petals of the corolla. The third kind is the larger and more robust species, *Galanthus plicatus*, a native of the Crimea. It may be distinguished at a glance from the former species by its taller growth, larger and more closely folded flowers, and its much broader foliage. The largest of our known Snowdrops is *Galanthus Imperati*, which may possibly be a chance variety of *nivalis*; and, if so, it tends to confirm the regret expressed by Loudon, in his "Encyclopædia of Plants," which is to the following effect:—"It is rather singular, and, also, to be regretted, that no variations or hybrids have been produced from this early and pretty little flower." The species or variety named *Imperati*, from its superior size, is not so pretty as either *nivalis* or *plicatus*, in consequence of its far less regularly-formed flower; but, in hybridising, it might prove a very valuable parent for the purpose of producing varieties, some of which might very probably prove superior to either of the parents. Such vast improvements

A group of Snowdrops on Root-work.

more so when made to appear in a seemingly natural locality of its own selection, as when its blooms are made to gather about the base of a mass of rock or root-work, such as that in the charming garden at Weybridge, alluded to in the last number of this journal. Snowdrops, as there introduced, produce the prettiest possible effect; especially where in sheltered nooks they bloom in closely assembled clusters, with more than usual luxuriance. The annexed wood-engraving of this wild little nook, exhibits three out of the four kinds that are at present known. To the right, straggling picturesquely among the interstices of the angular masses of Moss-grown root-work, is *Galanthus nivalis*, which delights in moist expanses of turf about the slopes of hills or the edges of woods and copses; and also the double garden variety, which, if less graceful than its simple, slender cousin of the woods, produces more effect, in consequence of its wider opening, caused by the expansion of the numerous green-bordered

have been realised wherever the system of hybridising has been perseveringly and skilfully carried out, that a few novel and charming varieties of our favourite Snowdrop may be expected so soon as some one or other of our enthusiastic florists determines to attempt the interesting work of a new floral creation.

It has been remarked that the Snowdrop, with all its exceeding grace and modestly-drooping beauty, and especially as fearlessly exposing its delicate milk-white bells to the storms and frosts of winter's most terrible month, should not have attracted the attention of our early poets. Chaucer, who found such daintily-delicate words wherewith to sing his exquisite song of the beauties of the Daisy, yet says nothing of the exquisite Snowdrop. Even Shakespeare, who with a touch, a single touch, has inimitably described so many of our native flowers, says not a single word of the Snowdrop. Even the truthful and poetic beauty of its name one would think

would, if he had heard of it, have charmed his pen to jot down some delicate epithet from which it would have been for ever inseparable. It is true that, if known in his time, it may have been called by another name, for we find our old botanist Gerard, a contemporary of the poet, speaking of it as the bulbous white Violet (*Viola bulbosa alba*). Yet this would not have deterred Shakespeare from bestowing his praise; for we find him exclaiming, "What is there in a name! a Rose by any other name would smell as sweet;" and surely, in his eye, the Snowdrop by any other name would have seemed as beautiful. It appears probable that the popular name of Snowdrop was not generally known in his time; yet, although a Latin denomination was preferred by the old botanist, he, nevertheless, admits that "some do call them, also, Snowdrops." There are, indeed, scores of poetic and appropriate popular names for plants that have never found their way into the works of learned classifiers.

Even in Milton's time the poets had not sung the charms of this delicate little flower, nor spoken of the interest of its early apparition, rising, as it often does, from a winding-sheet of snow, like the pale spirit of the departed flowers of the departed year. The explanation seems to be that, although now found wild in many parts of England, it was not originally a native plant, but was introduced from Italy at a comparatively early period, perhaps about the reign of Henry VIII., when foreign plants and trees first began to be largely introduced from the south of Europe and Flanders. It would seem that it was still rare in Elizabeth's time; and, though known to such indefatigable botanists as Gerard, was as yet a stranger to our flower-loving poets.

Tickell, the friend of Addison, is the first poet who mentions the Snowdrop, in his amusing poem, "Kensington Garden," in which he attempts to account poetically for its appearance in our parterres by a prettily conceived fairy tale, in which a metamorphosis into a flower takes place.

. . . the little shape, by magic power,
Grew less and less—contracted to a flower;
A flower, that first in this sweet garden smiled,
To virgins sacred, and the Snowdrop styled.

Thus won from death, each spring she sees him grow,
And glories in the vegetable snow.

Thomson, in his celebrated poem "The Seasons," does not overlook the graceful Snowdrop.

Fair-handed spring unbosoms every grace;
Throws out the Snowdrop and the Crocus first.

A passage which is prettily paraphrased by Savage—

The virgin Snowdrop first appears,
Her golden head the Crocus rears.

After that period, this little flower became a great favourite with our poets; and its modest drooping beauty is quaintly and fancifully made the theme of scores of more or less elegant verses, which, were one writing a monograph of the Snowdrop, could not possibly be passed over without quotation.

The restricted, but picturesque, domain accorded to this delicate flower among the artistic "radifications" of the Weybridge root-work, is so charming and so appropriate, that it forms a little flower-poem in itself—"a song without words," which leads naturally to the recollection of what some of our poets have said, or have not said, about our charming little friend *Galanthus nivalis*, and her near relative *plicatus*.

H. N. H.

ON PRUNING ROSES.

MANY fail in producing good Roses on account of not having a thorough knowledge of the operation of pruning. Nineteen out of twenty who attempt the pruning of Roses know nothing about the operation, although they may be clever in other branches of gardening; they cut away remorselessly at every variety alike, although it is well known that most of the yellow Roses cannot bear the touch of steel, neither will they live within three miles of a large town—they do not like smoke. Noisette and climbing Roses should be pruned very sparingly; merely cutting away the tip ends of the long shoots is quite sufficient, as all the bloom-buds spring from the ends of these shoots. Where there is too much wood, cut a good portion of it clean out from the base. The best instrument to prune with is the new French *sécateur*, with boxwood handle, the price of which runs from 4s. to 5s. This instrument is much superior to the common

pruning scissors. It makes a cut as clean as if done with a sharp knife; in fact, the cutting blade may always be kept sharp with the aid of a stone. I know of no pruning instrument equal to it. I will presume that the Rosarian is well acquainted with the habits of growth and other matters connected with the hybrid perpetual Roses, without which success is problematical and failure almost certain. I will proceed therefore to lay down some practical directions, which will be of some assistance even to the initiated as reminders, and by strictly following which the inexperienced may have good hope of success. I will suppose the operator placed before the tree designed for his attack, with the *sécateur* or Rose scissors. If a standard, he will have to consider the symmetrical shape of the head, and study the habit of growth of the variety to provide for it. He must also remark the condition of the individual plant, whether it is in good health and vigorous, or sickly and almost worn out, and form his plan of action accordingly. Having decided upon this, in operating, three things must be strictly stamped on his mind. First, vigorous growers must not be shortened or cut back so much as moderate or weakly growers require; about 9 or 10 inches of the last year's wood may be left in the former case, in the latter four or five, or even less. Second, every portion of dead or withered wood must be cleanly cut out; even such as apparently seems sound, if on cutting, the pith be found brown (caused by the ravages of an insect) must be entirely removed. Third, all cross shoots must be cut out, and the centre of the tree left as open as can be, in order to admit air and the sun. All thin and spindly wood must be removed, for it is impossible to get a fine Rose from such twigs, and in some varieties these weak shoots are numerous. Remove all such at once with a bold stroke. In all cases the branch must be taken off at a plump, healthy, well-developed bud, which must point outwards, and be cut at an angle of 45 degrees. The cut must also be clean—no splintering allowed. If not cut perfectly clean, another bud must be sought for lower down, and the attempt be made again. No snag ends must be left above the bud. Practice makes perfect, and the young amateur would do well to commence with inferior plants till he acquires decision and dexterity in manipulating his weapon. Bushes must be treated in a similar manner, noting particularly their habits of growth, but modified as to their forms according to circumstances. When bushes are grown upon Manetti stocks, one of the primary duties of the pruner will be to look for suckers, which in this class of plants steal up so insidiously from the part about the root, and so closely resemble the shoots of the actual Rose itself, as to require an experienced eye to detect them. The sucker may generally be known by the foliage having a shade of blue in it; but, in doubtful cases, it is best to trace it to its origin, removing the soil necessary for the purpose, when, if an impostor be discovered, it must be entirely cut away as close as possible to the stem, and the earth restored. In order to renovate an old plant, especially if a standard, the whole wood may be cut away down to the worked part, leaving the top somewhat resembling the knob of a walking stick. Large numbers of latent eyes will soon appear, a few of the strongest and best placed of which must alone be retained; the others must be removed with a sharp-pointed knife. Pillar Roses must be well spurred back to good, firm, and plump buds, always bearing in mind the habit of the variety, as previously remarked. Briars are very liable to send up suckers in the spring, especially before the head has developed its foliage, which gives it power to drawsap. If on the stock, they are easily eradicated; but, if from the ground, it will be necessary to throw out the earth with a fork, and their origin sought for and cut off close, as before observed. In a late cold spring, accompanied, as is often the case, with north-east winds, the operation of pruning ought never to be undertaken till the end of March, or, better still, about the beginning of April. If the nights are very frosty, pruning should be delayed, as it excites the plants, and too often the tender shoots and buds are damaged and destroyed by spring frosts even so late as May. When the young shoots are thus damaged, it is wise to cut back again to a good plump dormant bud, as it is an ascertained fact, that a good Rose can never be produced from young shoots which have thus been damaged. Tea-scented and China Roses—indeed, all the tender kinds—should never be operated upon until the end of April or beginning of May. Where the collection is a large one, it is better to prune at intervals, so as to secure a constant succession of blooms. When the work is completed, every particle of the wood should be raked off the beds; nothing looks so untidy as the prunings left lying about. To ensure the Rose trees doing well, every one should receive a good mulch of rotten manure, which should be pointed in around it, and a plentiful allowance of liquid-manure should be given once every three weeks during the growing and blooming season. This will ensure noble blooms, and promote the growth of robust wood for another season. Some varieties of Roses are very subject to throwing out one or more very robust shoots during the blooming season; this is

particularly the case with Gloire de Dijon. These shoots should be stopped by nipping out the points with the finger and thumb; laterals are then thrown out which flower abundantly. Indeed, with Gloire de Dijon, and other Roses of similar habit, it is the only method of obtaining an abundance of blooms.

HENRY TAYLOR.

PLASTERED EDGINGS.

OUR London Parks have of late years shown many improvements, but the raised mud-wall-like edgings of which we give an illustration cannot be included among them. Now and henceforward may be seen men with barrowfuls of a muddy and offensive compound, forming these miniature ramparts, which when first put up, and frequently for nearly the whole summer, are quite a blemish. Sometimes the plants above the edgings droop quickly so as to hide the eyesore, but none the less is the system an objectionable and needless one. These raised edgings were first employed for the display of plants with rosettes like the Houseleeks, but it soon came to be the fashion to raise every bed in this way. I maintain that in no case do the plants look better so arranged than in beds with a gently rounded margin. While, as to watering, the walled-up beds in the parks are watered with greater difficulty than the bed with the ordinary gentle slope. In addition to the offensive aspect of the little walls when first plastered up, there are the cracks which come after, and which are well shown in the annexed cut.

It is to be hoped that these edgings may not be imitated much in our private gardens, and that this fashion in our public ones may not endure long.

L. A.

SPRING-FLOWERING PLANTS.

As hardy plants of all kinds that blossom early possess unusual interest, some account of what I saw in this way, during a short holiday tour at Eastertide, may not be unacceptable. My first "call" was at Messrs. Rollisson's, where I found *Primula nivea* flowering freely, and in tolerable quantity. Its trusses, of snowy whiteness, are large and showy. Associated with it were *Androsace Chamæjasmæ*, another white-flowered plant, with a pinkish-coloured eye, and its relative *A. carnea*, a kind with rose-coloured flowers. Respecting *Primula nivea*, I observe complaints that it is difficult to cultivate; but here plants of it seem to thrive perfectly, even with little or no attention. In Mr. Parker's nursery, close by, I met with numbers of well-known spring-flowering plants, and also with others not yet so well known as they should be. Among the latter, the most attractive were a distinct species of *Narcissus*, named *triandrus*, a kind having flowers of a fine lemon-yellow hue; *Ficaria grandiflora*, a relative of our common Lesser Celandine, but in every way much larger, and thoroughly worthy of a place in all collections of early spring-flowering plants; *Triteleia uniflora* *lilacina*, a fine variety of the now well-known common form, having flowers of a fine mauve colour; *Puschkinia scilloides*, a showy bulbous plant, allied to the Squills, bearing handsome racemes of bell-shaped flowers; a nice tuft of *Saxifraga Rocheliana*, a mass of large white flowers; and *Arabis purpurea*, a low-growing kind, bearing a profusion of lilac-coloured blossoms. Foremost among plants of a more common description were *Anemone apennina*, of which there was a large patch finely in flower, large quantities of various Grape Hyacinths, a very fine tuft of *Doronicum austriacum*, than which I know of nothing more striking and beautiful amongst herbaceous plants in April, being, as it is, literally studded with golden-yellow flowers, some three inches in diameter. *Othonna cheirifolia*, an old Composite plant of distinct habit and foliage, is also now studded with yellow blooms, and a good assortment of Daffodils, conspicuous among which were the varieties known as the Emperor and Empress, both large and fine kinds. At this establishment, too, I noticed a good collection

of aquatics, amongst which *Aponogeton distachyon* was finely in flower; and I also observed a nice tuft of *A. d. minor*, sometimes called *longifolium*, together with another kind called *A. acuminatum*, and a very nice tuft of the lesser double Marsh Marigold (*Caltha palustris flore pleno minor*). In Mr. Barr's grounds, which are contiguous to those of Mr. Parker, I found a grand display of Daffodils, consisting of nearly all the sorts in cultivation. Conspicuous amongst them were *Narcissus minor*, of which there was a large patch densely ornamented with orange-yellow flowers, the "noses" of which, as Parkinson says, "do lie on or touch the ground." Of *N. odorus* and its varieties, bicolor, and numerous forms of *N. poeticus*, there was no scarcity. Masses of Grape Hyacinths, Fritillaries, Summer Snowflakes, and various other hardy bulbs, I also found here in profusion. Here, too, I met with a good bed of the lovely *Collinsia verna*, studded thickly with showy sky-blue and white flowers. This, though seed of it has been offered annually for these past ten or twelve years, is by no means an annual often met with, a circumstance attributable, I think, to a want of knowledge as to the best time of sowing it. The seeds of the plants here were sown last September in the open ground. The white-flowered variety of *Sisyrinchium grandiflorum*, a fitting associate for the common form on rock-work or on sheltered sunny borders, was also in flower in these grounds, in which I also noted several other highly interesting plants, such as *Erythronium grandiflorum*, *Cyclamen repandum*, one of the prettiest and most lasting of what are called Sowbreads, its deep purplish-crimson flowers having been produced in abundance during the past two months; and a good batch of the Golden Plover variety of *Primula elatior*. To visit Kew was my next determination, and, on my way to the herbaceous department, I passed through one or two of the plant-houses. On the shelves of No. 4, the show-house or conservatory, I noticed a couple of variegated hardy plants that are especially well suited for pot-culture, viz., *Funkia undulata* *variegata*, used as an edging to beds at Battersea, and *Hemerocallis Kwanza* *variegata*. During the early spring months, the foliage of these two plants is highly attractive, owing to the distinct character of its variegation. the usual spring-flowering climbers are made use of here, such as *Kennedya*s, *Hardenbergias*, and *Clianthus*, and among others I noticed a handsome free-flowering plant which is not so frequently met with as it deserves to be. I allude to *Lonicera sempervirens minor*, the tubular flowers of which, hanging in scarlet clusters as they are at present, are very showy. Among other plants in pots, *Malvastrum capense*, a pretty shrubby white-flowered Malvad from the Cape of Good Hope; *Rhododendron ciliatum*, a pale-flowered Himalayan species; and *Thomasia solanacea*, a shrubby plant, producing an abundance of Solanum-like flowers, were to me the most attractive. In what are called the Alpine frames, I found several treasures, which, when sufficiently known and more plentiful, will be sure to be highly appreciated. First among these, was a variety of the Wood Anemone, named *purpurea* (why, I know not, as its flowers are sky-blue), a distinct variety, each flower being fully as large as a half-crown piece. The next plant that attracted my attention was a potful of *Trifolium uniflorum*, about an inch high, thickly studded with handsome rose-coloured flowers, just commencing to open. This little Clover, when plentiful, will, doubtless, become a useful plant for rock-work or for the front of mixed borders. *Androsace Laggeri* is another pretty plant thickly laden with deep rose-coloured flowers, and among others I noticed *Smelowskia alpina*, a diminutive white-flowered Crucifer, *Romanzoffia sitchensis*, somewhat resembling a small form of *Saxifraga granulata*; and a singular form of *Scilla nutans*, called *bracteata*, which has green bracts or leaves, interspersed among its blue flowers. The herbaceous grounds are, at present, comparatively uninteresting. I did, however, find in them a nice tuft of *Adonis vernalis*, flowering freely; several kinds of *Orobis*; a *Narcissus*, named *galanthifolius*, with flowers creamy-white throughout; *Andromeda tetragona*, and a few *Epimediums*. The last, however, owing to continual shifts and changes, are by no means so fine as they were a dozen years or so ago. *Narcissi*, too, at Kew are by no means equal to those in private collections, many of the species being so puny and miserable as to be scarcely recognisable.

T. S.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Mossy Group.

Saxifraga muscoides of Wulfen, is the patronymic I shall adopt as the typical specific title under which we shall find several well-defined and constant variations arrange themselves. Why Engler should have preferred in its stead another name, viz., *S. moschata*, of the same author, I am at a loss to know. The former is in every sense of the word, appropriate, seeing that it means the "moss-like" Saxifrage, and conveys at once in its title the special characteristic of the plant; the latter, most inappropriate, meaning, as it does, the musky Saxifrage, thus endowing it with an odour of sanctity which I have yet to learn that it possesses even in the smallest degree. Nevertheless, some of my botanical friends will say—"Oh! but you are ignoring that grand fundamental law, that priority in matter of time gives precedence in plant nomenclature." I am, however, at a loss to see the sense of perpetuating an inappropriate name through all time on any grounds whatever, and have selected that which I consider best. Another synonym which is equally appropriate with the above, is *S. muscosa*, given by Suter in his "Swiss Flora." The typical species may be thus briefly described as forming a dense hemispherical mass of beautifully even green rosettes. The radical leaves, or those of which the said rosettes are composed, vary somewhat in shape; occasionally they are linear, but, when carefully dissected the one from the other, it will be found that the great majority are three-cleft at the apex—the centre division, extending far beyond the two secondary lobes, becomes linear in shape, and hence the plant has been described by some authors as possessing only linear leaves; the foot-stalk of each leaf clasps the parent stem in a sheathing manner; the flowers are produced freely, and are supported in groups of two or three on stems about 3 inches high, each flower being subtended by a foliaceous bract, and the whole of the stem, bracts, and calyx covered with a dense glandular pubescence. The petals expand horizontally, and are of a greenish-buff colour, varying with age to yellowish-buff. Neatness of habit, regularity and symmetry of growth, recommend this species to general notice more than anything in the way of brilliancy. This little plant is said to be found among our native Saxifrages growing in the lake district, but it is so long since the locality has been verified, that we may take it for granted that it has disappeared—in fact, there always was a general air of doubt as to its being indigenous. Be this as it may, it has no narrow or limited notoriety on the continent, where it grows in some of its modified forms through almost the entire Southern Alpine region; singularly enough, though not recorded in the north, I have received it in one of its most minute forms from Iceland.

S. muscoides var. *pygmæa* of Haworth, has all the peculiar beauty of the present species—not reduced to be in keeping with the diminished size of the pygmy plant—but absolutely concentrated, thus, making this variety decidedly the more beautiful of the two. The leaves of its tiny rosettes are more fleshy than the former, broadly rounded at the point, notched into three equal little lobes, and never presenting the linear form; each leaf is incurved like a little shell, and the whole plant is a very model of neatness; the flowers are greenish-yellow, produced freely on glandulose foot-stalks scarcely 2 inches high; both the original species and its pygmy sport are readily amenable to cultivation, and thrive in any light garden soil, but both are slow growers. It is a native of the Pyrenees, the Maritime and the Tyrolean Alps, and, very possibly, has a wider range, but being so minute and compact in its growth, it would be readily overlooked by the plant collector.

S. muscoides var. *crocea* of Gaudin.—This variety, which has long been known in cultivation as *S. atropurpurea*, a name that must have appeared to many cultivators, as well as myself, thoroughly inapplicable, especially as its blossoms, when they expand, are invariably of a yellowish colour, and, as they die off, acquire a slight chocolate tint along the margins. I have grown it for years, and have occasionally seen the faintest pink suffuse the petals of an old flower here and there, but that formed the only faint shadowy approach to the dark purple colour its name would indicate. There is no doubt, I think, that it should be correctly considered the variety *crocea* of our typical species *muscoides*. Its rosettes are much larger and more lax than in either of the previous varieties; the leaves are sometimes linear and entire, and sometimes divided at the points into three linear segments; the whole is of a dark green, and forms nice compact free-growing tufts. The flowers, the colour of which I have before described, are produced pretty freely, and supported on foot-stalks about 4 or 5 inches long. Its only wild habitat, as recorded, is on the Savoy Alps.

S. muscoides var. *atropurpurea*, of Sternberg, produces rosy-purple flowers. I should very much like to have cut off the first portion of the specific title and left it as *purpurea* alone, but when I give my

readers the history of this variety as I now possess it, they may, possibly, agree with me that it may yet claim the specific name in its full intensity. So to my little history. About five years ago, I saved a pinch of seeds from the so-called species *atropurpurea*, with yellowish flowers, and sowed them, not that I expected any special result whatever therefrom; during the summer they were potted off into small pots, and left to the chapter of accidents; the following spring I was no less surprised than delighted to find the first to flower produced petals as highly coloured as the well-known *oppositifolia*, in fact, a beautiful rosy-crimson, and, what is more, with only three exceptions in the dozen plants, all had the same beautiful colour, with varying shades of intensity. Especially interesting is this little episode in my Saxifragean experience, in the fact, that I never remember the general rule so markedly set to one side, that seeds, when once the specific identity is broken, always tend to depart from the parent type; here, in place of departing from it, they absolutely restored a character which, doubtless, once existed in the parent plant, but had been, to my knowledge, long lost; such an occurrence has an interest far beyond my paper on Saxifrages. Having thus given you the origin of my becoming possessed of the true variety *atropurpurea*, I should add, that in addition to the altered character of the flowers, there is a difference in the foliage, all the leaves are trifurcate, and from the original rosettes short procumbent stems are freely given out, so that it is not so caespitose or tufty in its growth, and, in fact, is a freer grower. I wish it were a more abundant bloomer, and have no doubt that when it has fresher air and less smoke than as cultivated in our old garden it will improve in the latter respect.

S. Rhei, though classed by Engler as a more lax form of *S. muscoides*, is sufficiently distinct to retain its old specific title as given to it by Schott. It appears much closer allied to the following than the preceding species; it forms large compact rosettes with leaves three to five-lobed; it produces from the base of the old rosette several little procumbent short shoots, the arrestment of whose terminal growth constitutes the rosettes for the following year. Its flowers are few, of a greenish colour, arranged in a capitate manner, and supported on a leafy peduncle, 3 or 4 inches long; the whole plant is covered with a very short pubescence. My original plant came from Corsica, and maintained its distinct character for a series of years, but all seedlings, raised on several occasions, merely seemed to rival one another in their divergence from the parent type.

S. exarata of Villars and *nervosa* of Lapeyrouse are names with which all Saxifrage growers will be familiar; so similar, however, were the plants that represented these names, it did not require much examination to determine that they were really identical, and both referable to *S. exarata*. Within recent years the true *nervosa* has got into cultivation, and I am quite disposed to endorse Engler's idea that it is a variety of the species with which it has been so long confounded, and, as such, I shall consider it. Our typical plant is a nice dwarf compact grower, of caespitose habit, and a peculiar greyish-green foliage. Its rosettes consist of five or six upright leaves, three-cleft at the summit, with a long narrow blade below, running down into the stalk. The flowers are white, suffused with a greenish tint; they rise from the axils of leafy bracts, four or five being borne on each peduncle, and the whole plant is covered with a short pubescence, which assumes a true glandular character in the flower-stem and calyx. It is a very free grower, and a good distinct species, retaining its character well from seed. The plant enjoys a wide European distribution, being met with in almost all southern Alpine districts.

S. exarata var. *nervosa* of Lapeyrouse, is a perfectly-formed diminutive variety of the former, hardier and more woody in texture. It grows in dense compact little tufts, usually most at home in the chinks and crevices of the rocks; in fact, it holds just the same relationship to its specific type as *pygmæa* does to *muscoides*. The variety is recorded as found abundant on the Pyrenees and the Maritime Alps, and, possibly, has a wider range. In cultivation it likes a fair admixture of peat soil, good drainage, and a firm nip between the stones, whether grown in a pot or in the open rockery.

S. pedemontana of Allioni, a good distinct species, is a native—as the name implies—of the Maritime Alps, near Piedmont. It forms somewhat lax rosettes of broadly cuneate leaves, gradually narrowing down to the base of the petiole; the leaves are covered sparsely with short erect glandular hairs, which form a marked ciliatory character to the margin of the leaf; they are three-cleft, the two lateral clefts being again notched or divided, thus giving the appearance of being five-cleft; the divisions are erect, about uniform in length, and somewhat acutely pointed, with a slightly scarious termination. The flowers are produced on slender glandular pedicels, the foliaceous bracts that subtend each flower being first five-cleft, then three-cleft, and, ultimately, entire. They are pure white, and are sometimes so closely aggregated together as to give them a

capitate appearance, while the bracts assume the character of a well-defined involucre. The petals are obovate, tapering towards the base. Though not a rapid grower under cultivation, it is stated, in its native habitat, to form large pillow-like masses of a beautiful lively green. It is not absolutely confined to the Piedmont district, as its name might be supposed to indicate; but occurs pretty freely through the Swiss and Tyrolean Alps.

S. aromatica.—This I purpose substituting for the garden name *corsicana*, which has been given to a very distinct species of Saxifrage introduced from Corsica, some three years ago, by our indefatigable friend, Mr. Maw, for reasons which I shall presently explain. I have examined it carefully, and do not find any described species in Engler's "Monograph" to which it can be referred. Seeing that this is the most recent enumeration of the present known Saxifrages, I therefore conclude that it must be new, and feel almost disposed to give it a new name, based on the great resemblance of its leaves, when in a fully developed state, as they occur in the mature rosette, to the fleshy and powerful fore-feet of the mole. I thought of suggesting the specific name of *S. talpædiformis*. This, however expressive, is objectionable on the score of length. During the process of minute examination, I detected a delicious aromatic perfume given out from the resinous glands of the young growth, and it struck me that the specific title *aromatica* would be equally appropriate and certainly more

euphonious. This, therefore, I have adopted. A brief description of the plant is as follows:—dense and somewhat hard in growth; its rosettes are large, nearly $1\frac{1}{2}$ inches in diameter. The leaves are fleshy, exceedingly broadly wedge-shaped, notched at the upper part with five tolerably deep segments, the two lateral ones being each further subdivided, making each leaf appear seven-cleft; the entire portion tapers rapidly into a somewhat broad and short petiole, provided at the base with long irregularly-jointed cilia; the whole surface of the leaf, especially on the upper side, being covered with short glandular erect hairs; the points of each of the linear divisions are slightly mucronate and incurved. The young branches given off from the base of the rosette are coral-like red in colour, erect in habit, and provided with leaves, which appear to vary a good deal in the depth and number of indentations;

sometimes the divisions are obtuse, sometimes acute; in every case, the petiole rather exceeds the blade in length; the young growth is as remarkable for laxness as the mature rosettes are for denseness in their leaf arrangements. The inflorescence consists of a leafy lax cyme 6 or 7 inches high, branching from the bottom, the lower leafy bracts being trifurcate, the upper ones entire, the whole covered with short glandular hairs; the divisions of the limb of the calyx are lanceolate, incurved at the points; the petals are pure white, obovate and unguiculate; of this species, no doubt, the true position will be between *gerainioides* and *ladanifera*; to the latter it claims relationship in the resinous perfume, to the former in the peculiar branching character of the cymes.

CASTOR-OIL PLANTS.

At page 75, vol. V. of THE GARDEN, we gave a descriptive list of a number of the best varieties of the Castor-oil plant (*Ricinus communis*), now in cultivation, together with an illustration of one of the finest and most effective kinds, *R. sanguineus*, so named from the blood-red colour of its stem, branches, leaf-stalks, and larger leaf-veins or nerves. Of this plant, our present illustration represents more clearly the appearance of the inflorescence, and the contour of the individual leaves. The habit of the entire plant is well shown in

the figure on page 75. To those who have seen the splendid specimens of Castor-oil plants thriving as they do during summer, in the open air, in Regent's Park, and elsewhere about London, it is hardly necessary to recommend them as ornamental subjects of a very high order. Their culture, moreover, is attended with no difficulty. The seed should be sown in heat, about the middle of February, and the plants should be gradually hardened off, so as to be fit to put out by the middle of May; the better and richer the soil, and the warmer the position, the finer and more vigorous will be the growth of the plants. In summer, copious watering is indispensable. The *Ricinus*, in most of its varieties, is a grand plant for making bold and effective beds near those of the more brilliant flowers, and tends to vary the flower-garden finely. It is not well to associate it closely with bedding-plants, in consequence of its strong growth and the shading power of its large leaves. A good plan is to make a compact group of the plant in the centre of a wide circular bed, and surround it with a band of a dwarfer subject, say the *Aralia* or *Caladium*; and then finish with whatever arrangement of flowering plants may be considered most suitable. A bold and striking centre may thus be obtained, while the effect of the flowers is much enhanced,

especially if the planting be nicely graduated and tastefully done. For such groups, the several varieties of the Castor-oil plant are not to be easily surpassed.

Foliage and flowers of *Ricinus sanguineus*.

Select Dahlias.

—Will you kindly furnish me with the names of a few good Dahlias both ordinary and fancy kinds?—ARDOCK. [The following are excellent varieties, viz:—Acme of Perfection, primrose yellow; Ada Tiffen, light peach, tinged with rose; Alexander Cramond, maroon, shaded with crimson; Arbitrator, buff or fawn, suffused with purple, yellow at the base of petal; Blue Beard, shaded crimson; Cremorne, yellow, tipped with red; Crimson King, fine crimson; Duke of Edinburgh, deep yellow; Duke of Cambridge, shaded orange; Emily Williams, light ground, edged and tipped with vermilion; Herbert Turner, French white, with soft tinge of lilac;

James Cocker, purple; James Service, dark crimson; John Standish, bright red; Lord Hawke, yellow buff, tinged with red; Lord Salisbury, light rose, heavily tipped with lake; Maid of Essex, pale ground, regularly tipped with rosy-purple; Marchioness of Lorne, orange, lightly edged with purple; Miss Bateman, yellow, suffused with red; Mr. Sinclair, rose, tipped with purple; Mrs. Austin, yellow, edged with red; Ne Plus Ultra, fine lilac; Prince Arthur, beautiful clear yellow; Sarah Read, light ground deeply edged with pink; Thomas Goodwin, very dark maroon; Thomas White, very fine maroon; William Keynes, orange; William Pringle Laird, lilac. *Fancy Dahlias*:—Carnation, clear white, deeply flaked with dark rosy-purple; Dolly Varden, white, striped with purple; Egyptian Prince, bronze red, striped with deeper red; Harlequin, white, striped purple; Herbert Purchase, rosy ground, striped and mottled with crimson; Jessi Gill, yellow ground, striped with rose; Lady Spokes, striped, fancy white mottled and striped with pink; Laura Haslam, pale yellow, tipped with white; Marquis of Lorne, light ground, flaked with purple; Monarch, very dark, tipped with white; Mrs. Bennett, light ground, striped with lilac; Mrs. Goodwin, fawn ground, striped with red; Mrs. Saunders, the finest fancy Dahlia of its class, yellow, tipped with white; Rev. J. B. M. Camm, yellow, flaked with red.—ED.]

Edgings for Garden Walks.—Various plants have been recommended for forming edgings to garden walks, but I suppose none are so universally used as dwarf Box, and where Box will grow freely

and well, few people will be disposed to look for a substitute. However, there are places where Box does not thrive well. In a general way, it does not flourish in dry hot soils or in very shady places, and, under unfavourable conditions, it is apt to die off and become patchy, and in consequence looks untidy. Amongst plants, that make a neat edging in situations where other things do not thrive, may be mentioned the various forms of hardy Sempervivums or Houseleek. They will grow anywhere, and there is no particular preparation required like what is necessary for Box. One or two rows may be planted close together, and a neat thick edging is formed that scarcely anything can improve. In planting, it will be necessary for the sake of uniformity to plant each row of one size. And if once or twice during the summer the offsets are pricked off before they attain any size a perfect outline will always be maintained.—E. HOBDAV.

Bulbous Roots adapting themselves to their proper Depth in the Earth.—My attention was first directed to this some thirty years ago. In a garden at Pontefract, I made several alterations, one effect of which was to disperse and bury, 12 inches under the surface, a bunch of Snowdrops. At their usual season several of them duly sent up leaves and flowers. As soon as the foliage began to decay I took them up, with the view of planting them again in a cluster. I was, however, surprised at finding that the old bulb at 12 inches deep in the ground had entirely perished, except the skin and stalk. Upon the latter a new bulb had formed, about 4 inches under the surface of the soil. This proved to be the case with all that I dug up. The circumstance had escaped my memory until last year, when (thinking I should leave my present house and garden) I dug up my tulip roots. I found that some of them had been raised above their proper depth in the earth, and that some were upon the surface. The latter showed a skin the size of the original, but contained merely a small offset, about the size of two Wheat-corns. A tap-root had struck down, from which, at 4 or 5 inches below the surface of the earth, strong healthy bulbs were thrown off. It is desirable to ascertain what bulbs obey this law.—THOMAS ARNALL, in the *Pharmaceutical Journal*.

Flowers in Devonshire in April.—Orchards here are now gay with groups of Daffodils and marshy banks with Caltha, the former pale yellow, the latter shining gold. On the bank of the high road between Ottery and Sidmouth we met with the beautiful blue Periwinkle. Primroses are in wonderful profusion—banks and hedgerows, fields and ledges of the cliffs, being full of them. Ferns are just beginning to show, the black Spleenwort is spreading out its bright green fronds, and the Hart's-tongue is gradually uncurling. Long tendrils of Bramble have just begun to overhang the sandstone rocks through which the road is cut. All the Devonshire Apple trees are draped with grey Lichen, which, before the leaves and blossoms appear, gives the orchards an ancient and weird appearance. Golden Saxifrage forms a brilliant carpet in the glen of Harpford Wood. This little plant has a most charming effect when growing in masses between beds of Fern and wood Anemones. In some of the lanes we have found the Columbine, or Aquilegia, not yet in bloom. We had been told that Cowslips do not grow in Devonshire, but although in the meadows their places seem usurped by Primroses, yet close to the sea-coast we have found many plants of Cowslip; near Torquay the cliffs are covered with them. Thrift, which forms delightful blue-green pincushion-like tufts on the ledges of the Sidmouth cliffs, is now covered with pink blossom. Gorse is, also, here, as elsewhere, in full blossom, and between the bushes the turf is studded with Dog Violets. Alkanet, the flowers of which are bright dark blue, grows in the lanes and is very handsome. Near Brandscombe we found the Creeping Lithospermum (*Lithospermum purpureo-cæruleum*), which has a dark green leaf and sessile flowers of blue and purple colours. In cottage gardens the favourite flowers appear to be Anemones. Camellias, too, are in blossom out-of-doors.—MARY.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Weeds on Walks.—Can any of your correspondents inform me what is the best application for destroying vegetation on gravel walks? I am told that one part sulphuric acid to eight parts of water is good. Salt, I find, is only a temporary cure.—J. G., *Dulwich*.

A New Hardy Clematis.—MM. Thibaut and Keteleer announce, under the name of *Clematis integrifolia* de Durand, a new hybrid between *C. integrifolia* and *C. lanuginosa*. It grows about 4½ feet high, and bears large dark violet velvety flowers, from 3 to 4½ inches across, with yellow anthers. It blooms continuously from the end of May to the middle of October.

Helleborus niger major.—All who are interested in the decoration of outdoor gardens in the latter end of October and in November, should, in addition to Asters, Chrysanthemums, Sternbergias, and Colchicums, procure some of this variety of Helleborus. It is not the old and well-known Christmas Rose; on the contrary, it differs from it in flowering quite a month earlier, and in producing larger blooms. The old variety forms a good succession to this kind of Christmas Rose, which succeeds perfectly in any ordinary garden soil, and without any special care whatever.—W. F.

THE INDOOR GARDEN.

THE SCARLET TREE-RHODODENDRON.

THE Tree-Rhododendrons in the conservatory of the Botanic Gardens, Regent's Park, have been very magnificent this season, and are still in considerable beauty, though their time of greatest glory is nearly over. The Rhododendron, or tree of Roses, as its name implies, is certainly one of the most splendid of the flowering-shrubs that horticultural enterprise and skill have introduced and naturalised in our gardens; and if the grand Tree-Rhododendron of Nepaul, a true tree, which attains, in our conservatories, a height of from 15 to 25 feet, could be acclimatised, either by a long succession of seedlings raised in the open air, or by judicious hybridising, so as to stand our winters without artificial protection, it would take rank as the grandest of all ornamental flowering trees; for a tree it is beyond dispute, with a straight sturdy trunk, often rising to a height of 8 or 10 feet before it branches. It is possible that, by hybridising, the tree habit might be lost in the bush character of most of the other kinds, and then, the special object of the treatment would be lost, however splendid the flowers of future hybrids might prove, as they have already done. It is, therefore, from seeds of pure strain, raised in the open air, or, at all events, pricked out very young, that the desired result is the more likely to be achieved. When we note what splendid success has followed the earnest and persevering treatment of the Clematis tribe, nothing need be despaired of. Even with the broad-leaved Lilac, so indisposed to "sport," considerable success has been attained; the grand variety named in honour of the late Dr. Lindley being an infinite improvement upon the original species, handsome and free-flowering as it is, and one of the chief glories of our spring shrubberies; for the new Lindleyana flowers even more profusely; the trusses of flowers, as well as the individual flowers, being larger, and the scent (of sweet spring-like character) more powerful, and, at the same time, more delicate. With these successes in full view, to say nothing of the charming novelties which we enjoy in the splendid array of double-flowered and grandly-foliaged Pelargoniums, as well as many other novel and scarcely-to-be-expected results of persevering horticulture, there is hope of seeing Tree-Rhododendrons ornamenting our shrubberies, gorgeous with hundreds of great scarlet trusses of flowers, each truss as big as a bunch of Pæonies. Many of our leading nurserymen have risen to the height of real science in their profession, and are true artists in their pursuit of magnificent colouring and its endless blendings, from the fullest and most dazzling tones to the most soft and delicate tintings; all of which the nature of their studies and the practised experience of a cultivated eye enable them so well to appreciate and so often to realise, even beyond their own most sanguine expectations. The Persian king of the old story, *blasé*, satiated with all existing pleasures, and sighing for a new one, might, perhaps, not have been so long disappointed had he lived in our time, and asked one of our magic-working nurserymen for a new flower, more fair, more sweet, more beautiful even than the Rose. So, like the Persian King, I fearlessly ask for a new pleasure, and beg that it might be a hardy scarlet-flowered Tree-Rhododendron; and doubtless, after this notice, and a little patience, I shall be sure to get it, notwithstanding many difficulties that might be urged; for my horticultural friends are Napoleons in their way, and have expunged the word "impossible" from their vocabularies. H. N. H.

CHRYSANTHEMUMS.

THERE is no better time than the present at which to commence the culture of this deservedly popular flower. Cuttings struck now will make fine bushy plants from 18 inches to 2 feet in height by next October, and when in this dwarf state and well-flowered, they are better for small conservatories, or for the ordinary purposes of indoor decoration, than plants of larger size. Some prefer to propagate their plants in the autumn, but I have for some time discontinued the practice, since spring-struck plants are, for decorative purposes, better in every respect; and it is now possible to purchase cuttings of

all the best kinds, and these actually cost less than the expense of saying nothing of the trouble, incurred in wintering old plants, or autumn-struck cuttings. Many years ago poor old Sam Brpome taught us the value of the Chrysanthemum as a decorative plant for town gardens, but, as a class, horticulturists seem slow to learn and put into practice the annual lesson still taught in the gardens of the Middle and Inner Temple, where local circumstances and surroundings are by no means so favourable for vegetation, as the more open suburban parks and squares, and private gardens. If Chrysanthemums are now thought of, put in the cuttings at once, and they will be well rooted in a fortnight in a propagating case or frame. Directly the young plants commence to grow, stop them at the third or fourth joint, this will cause them to throw out laterals and make them bushy, and as soon as they break again pot them, say, two or three together in a 12-inch pot. The small-flowered kinds, or Pompons, do well two together in 32-sized pots, and make fine bushy little specimens either for conservatory or window decoration. The Chrysanthemum is one of the quickest-growing plants we have, and is a gross feeder, and nothing suits it better in the way of compost, than a mixture of fibrous loam, road-scrappings, or coarse sand, and one-third well decomposed hot-bed manure. Set the plants outside towards the latter end of May or beginning of June, and never let them want for water, or the loss of their lower foliage is an inevitable consequence. As soon as the pots get full of hungry roots, water liberally with clear manure-water, gradually increasing the strength as the flower-buds appear. The plants should be neatly tied out to stakes, as this not only improves their shape, but makes them form a sturdier growth, by admitting a more extensive circulation of light and air. This last point is of immense importance in the culture of all decorative flowering-plants. Plants grown as above recommended will be found useful additions to the greenhouse during the dull autumn months, when flowers are generally few and far between in most small establishments.

J. T. S.

THE CINERARIA.

FOR the decoration of a cool greenhouse or conservatory few plants that involve so little trouble are more showy in early spring than the Cineraria. Seedlings, if the seed-bearing plants have been carefully selected, are now generally so good that, except for the purpose of exhibition, it is hardly necessary to grow named varieties. When Cinerarias are required for winter blooming, the seeds should be sown early in April so as to give time for the plants to be grown steadily on without any undue excitement in the shape of fire-heat; in fact, from the time the seeds are sown till the plants are in flower the less artificial heat, beyond securing them from frost, they have the better. Under cool treatment, and if well supplied with water and freely ventilated, their growth is robust and firm and less liable to the attacks of insects. If in any stage of their growth they are kept too close and warm, green fly will surely make its appearance, and Cinerarias do not stand fumigating well. I have seen more than one lot of good plants destroyed by careless fumigating. Sow the seeds thinly in a mixture of sandy-loam and leaf-mould (about one part of the latter to two of the former). Cover the seeds with silver-sand, and place a square of glass over the pots or pans in which the seeds are sown. This obviates the necessity for much watering, which has a tendency to sour the soil, and carry small seeds down too deeply for quick germination. The seed pans may stand in a close frame till the seedlings are large enough to handle, when they should immediately be pricked off 2 inches apart in pans or boxes, and the frame kept close for a week or so afterwards, when a full and free ventilation may be given. The great thing is to grow them on steadily, never allowing them to experience any check, either from want of water or root-room. Many seedlings are irretrievably ruined in the seed pans, and no after care or management can effectually remove the debility contracted by bad treatment in early youth. When the leaves of the young plants begin to meet in the pans or boxes, they should be potted singly into large sixty-sized pots, and should stand in a cool frame facing the north, in coal-ashes, and should after the first week have abundance of air, even to the extent of removing the lights in calm, warm weather. The attention required from this time onwards consists in shifting them into larger pots as they require it, liberally supplying them with water, and, also, on hot bright days damping the ashes around them. This, even in the hottest weather, will cause a nice genial atmosphere to surround the plants, from which they will derive immense benefit. This last shift

into the blooming pots when the plants are required for very early blooming should be not later than the end of August, so as to get the pots well filled with roots before the short days. The strongest plants may be potted in 8-inch pots, which is large enough for good specimens, and the smaller plants into 6-inch pots. There is never anything gained by over-potting, but rather the reverse. For the last shift, the soil may be richer, and may be composed of about two-thirds of good fibry loam and one-third old decayed cow or pig-dung, thoroughly mellow and crumbling, and just a sprinkling of soot may be added. If the loam is very adhesive, a sprinkling also of coarse sand or crushed charcoal will be beneficial. In all stages of their growth the pots should be well drained, for, though the Cineraria delights in moisture, anything in the shape of stagnation is fatal to success. In potting (the last shift especially) ram the soil in the pots firmly. Loose potting, when applied to soft-wooded plants, may, for a time, induce rapid growth; but if you want bushy sturdy plants, with the growth built up solidly, to be succeeded by an abundant bloom, firm potting is essential. A plant that is firmly potted has more food available within its limited space, and will not suffer so much from drought, if by any chance any delay has arisen in watering. For late blooming, June will be time enough to sow the seeds. I have often selected a few of the best seedlings in May, just before they had done blooming, placed them in a coal-ash bed under a north wall, where, without any trouble, they ripened and scattered their seeds, which quickly came up by thousands; and I have never had healthier or stronger plants for spring blooming than I have obtained from this somewhat primitive method. The truth is, there is far too much nursing and coddling with this class of plants, and that is the principal reason why they are so susceptible to the attacks of insects. An acquaintance of mine, some years ago, used to grow for market Cinerarias and Calceolarias with amazing success. His houses were simply dug out of a stiff clay soil, and the earth from the pathways formed the beds on each side, on which the plants were placed, covered with a low-span roof, not over-well glazed. The plants stood on a cool bottom near the glass, were never over-heated, and had an abundance of ventilation, and, as a consequence, were free from insects, and grew with remarkable vigour. In a well-constructed house, the chief causes of failure in this class of plants are deficient ventilation, too much artificial heat, and a lack of humidity in the atmosphere. One word more as to liquid-manure. This may be beneficially given at every alternate watering after the flower-buds are formed. If given clear, and not strong, the plants will flower largely, and the flower will be finer. There is nothing much better than sheep droppings, with a little soot added, for soft-wooded plants.

E. HOBDAV.

Small Conservatory Stove.—In THE GARDEN of the 7th ult., I notice an inquiry as to the best stove for a small conservatory. There is a capital American stove which, if it can be had in England, would exactly suit your correspondent. It is called the "Beacon Light Base Burner," a self-feeding stove; the coal chamber holds sufficient to burn over twelve hours without any attention whatever, and it gives out sufficient heat to keep out 48° (F.) of frost, or 16° below zero, as we have had it here this winter. There are several sizes. I have had one of the smallest in use for two winters, and it works admirably. In your comparatively mild climate, I doubt if it would require to be supplied with coal more than once in the twenty-four hours; all that would be necessary would be to shake out the ashes morning and evening. The coal used is anthracite. There is no smell, no gas gets out of it, as it is close. There are panes of mica in it which give it a cheerful appearance as the fire is seen through them.—PETER JACK, *People's Bank of Halifax, Nova Scotia.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Leucopogon Richei.—This pretty little plant, though not very well known, is quite deserving of attention, both on account of the beauty of its flowers and their use in bouquets. They are white, delicately-scented, and retain their freshness for some time after having been cut. The plant is, therefore, a desirable addition to every collection.—R. B. F.

New Plant Manure.—M. Quihou has found M. Jeannel's mineral manure (see p. 152, vol. III. of THE GARDEN), to be useless and even injurious to many plants grown in the open ground, and also in pots under the usual conditions. The only instance in which he found it to be of any value was in the case of plants grown in small pots and in barren worn-out soil, that is, under conditions which very seldom occur.

Arthropodium cirrhatum.—This attractive New Zealand flowering plant has been cultivated in the succulent house at Kew, for some years. Mr. W. Bull recently exhibited a remarkably well-grown plant of it, bearing an erect branching spike of white star-shaped flowers. The plant is graceful in habit, being furnished with curving glaucous foliage about 2 feet in length, and from an inch to an inch-and-a-half wide. It blooms freely in a cool greenhouse or conservatory, and deserves more general cultivation than it at present receives.—A.

A HOLIDAY TOUR.

By THE EDITOR.

Two Great Artificial Waterfalls near Rome.

ARTIFICIAL WATERFALLS, like artificial rocks, are frequently more suggestive of the puerile than of the picturesque, and this not merely in small places, but in great public and private gardens, where no expense was spared in their construction. This being so, it should not be forgotten that two of the most famous waterfalls in Europe—famous, that is to say, for their sublimity and beauty, are both artificial. These are the falls of Terni and of Tivoli. The greatest is that at Terni; it is the result of one of the great works of the Romans before our era, and was made by conducting a river (the Velinus) over a precipice of great height into another river (the Vera). This was done in order to relieve a district of superfluous water, and to guard against inundations. The falls are in the neighbourhood of some striking woodland-scenery, the railway near at hand running on its way towards Rome, through some deep defiles clad with evergreen Oaks, that make the waving slopes charming indeed, as contrasted with the generally bare and brown hills of Italy in winter. Near, too, are the ruins of the bridge of Augustus, which formerly joined the hills above the river to allow of the passage of the Flaminian way, and is now a stately and picturesque pile, standing firm in the busy water, and abundantly draped with Maiden-hair Fern, and other plants. The most trustworthy evidence places the total height of the falls at between 800 and 900 feet, but some say they are nearer to 1,200 feet high. The fall is broken into three parts, an upper fall of about 60 feet, the second or great fall at something under 600, and, finally, the lower and more broken fall a rush of foam about 250 feet high. As it is not often that great poets condescend to describe artificial waterfalls, it will be best, perhaps, to quote Lord Byron's well-known description of the falls of Terni:—

The roar of waters!—from the headlong height
Velino cleaves the wave-worn precipice;
The fall of waters! rapid as the light,
The flashing mass foams, shaking the abyss;
The hell of waters! where they howl and hiss,
And boil in endless torture; while the sweat
Of their great agony, wrung out from this
Their Phlegethon, curls round the rocks of jet
That guard the gulf around, in pitiless horror set,
And mounts in sprays the skies, and thence again
Returns in an unceasing shower, which round,
With its unemptied cloud of gentle rain,
Is an eternal April to the ground,
Making it all one emerald:—how profound
The gulf! and how the giant element
From rock to rock leaps with delirious bound,
Crushing the cliffs, which, downward worn and rent
With his fierce footsteps, yield in chasms a fearful vent!
To the broad column which rolls on, and shows
More like the fountain of an infant sea
Torn from the womb of mountains by the throes
Of a new world, than only thus to be
Parent of rivers, which flow gushingly,
With many windings, through the vale:—look back!
Lo! where it comes like an eternity,
As if to sweep down all things in its track,
Charming the eye with dread,—a matchless cataract,
Horribly beautiful! but on the verge,
From side to side, beneath the glittering morn,
An Iris sits, amidst the infernal surge,
Like Hope upon a death-bed, and, unworn
Its steady dyes, while all around is torn
By the distracted waters, bears serene
Its brilliant hues with all their beams unshorn:
Resembling, 'mid the torture of the scene,
Love watching Madness with unalterable mien.

Byron thought the falls of Terni "worth all the cascades and torrents of Switzerland put together." The cascades at Tivoli are no less interesting. Our excellent page illustration of these will show what they are better than any words. In this case the great falls of the river Anio tumble into the valley from a height of about 320 feet. Here the smaller falls or cascatelles are mill-streams, &c., artificially diverted from the river, and the course of the great cascade itself was diverted into a new channel in consequence of an inundation in 1826. Here the landscape surroundings of the falls, the associations

of the place, and the rich vegetation, all combine with the falls to produce a very charming effect. With these facts before us who shall say that artificial waterfalls, &c., must, of necessity, be either puerile, or in any way, less satisfactory than any others? Good opportunities for making the like seldom exist, and where they do not, the best way would be to be content without making any attempts after the picturesque in this way. There can be no doubt, however, that many suitable situations for forming effective cascades exist in many of our great gardens and parks; and the result of turning a streamlet over the brow of a cliff or rocky brow, may be well worth considering by many interested in landscape gardening.

Florence.

A city cradled in many hills—hills dotted over everywhere with villas standing in vineyards and orchards, with which the country is so fully covered that there is no room for hedges or dividing lines of any kind. A fair city with many evidences of northern taste and neatness in its gardens; with most picturesque and interesting surroundings, and offering much more interest to lovers of gardens than Rome. Efforts are being made to improve its public gardens or promenades, and at great cost. The fortifications which once surrounded the city, like nearly all old Continental cities, have been removed, and the space thus cleared is occupied by public walks and gardens. Mars has, in fact, been thrown over for Flora—rare event. These gardens, where they deviate in plan from a planted road or avenue, seem to have but one fault; too many walks. To use an inch too much of these necessary, but not picturesque, objects is unpardonable. Here, in some places, there are four walks where one would suffice, and where there should be a pretty, if limited, expanse of Grass, there is a network of wide walks. A very bold improvement has been made here in the way of a public garden. A long and excellent drive winds up one of the hills immediately commanding the city, and affording many views of it and its surroundings. This new drive, admirably formed and planted, is bordered in many parts by gardens, all public property. These again, are somewhat disfigured by too much detail of the wrong kind in the way of grottoes, fountains, and high stone edgings, which, however, a purer taste will, it is to be hoped, one day modify. Florence is near the marble quarries, and takes advantage of the fact by placing marble seats in this new garden, each 12 feet long and nearly 3 feet wide, formed of one slab. It is not every city that can afford marble seats, but the use of stone seats in gardens is not uncommon as far north as Lyons, and it must be owned they look much better than those of either iron or wood. The limestone seats in the Lyons garden look quite as well as those of marble, and are good and massive in design. In these countries they have an advantage beyond that of not requiring paint, and they are not so easily burnt or made away with in times of commotion. Apart from these considerations, there can be no doubt that the use of stone seats of good and simple design, and of some easily-procured stone, would be an improvement in public gardens, &c.

The Boboli Gardens at Florence.

These have a good deal more character than is common in the best public gardens even of great cities. They resemble nothing else in the way of a garden in Europe. An illustration, published in THE GARDEN some time ago (p. 442, vol. iv.), conveys an exact notion of their general effect from one of the most important points of view. The whole is a curious mixture of palatial, botanical, and horticultural gardens, and, for the greater part, is on the slope of a steep hill, rising almost directly over the city. The main features are groves of evergreen Oaks and lines or avenues of Cypresses, the various gardens being arranged in spaces between these; and the effect, from want of breadth in any part, gives one the idea of wandering through the wards of a gigantic key. The longer and more open avenues sometimes have a striking, and withal a simple and quiet aspect. But, beyond this, the effect generally is as weak as it ever must be where the surface is frittered away, and there is no central lawn or opening. Many small and modest private gardens have a much more open, cheerful, and altogether charming effect, than such huge mazes. The Boboli Gardens are happy in a very army of

THE CASCADES OF TIVOLI.

statues, but their charms would be greater if all but half-a-dozen of these were removed; sometimes—as in the central avenue, where a bold group stands out clear against the imposing avenue of high Cypress trees—the effect is good. But when the eye catches sight of a company of the above-mentioned army, in skirmishing order, in front of a line of clipped trees, the effect, to say the most of it, is not of a very high order. It is spotty and meagre, and the eye is diverted from the trees without being consoled by the statues, which are frequently noseless. In discussing disfigurements of public gardens, writers usually take it for granted that the British rough or snob, or whatever he may be called, is the most savage of all, in this respect. And they sometimes mercifully account for his shortcomings by reminding us how far removed from all those refining influences of other and more artistic countries the poor fellow's experiences have been. Well, in no part of Britain can one see in any public garden so much and such frivolous destruction and disfigurement of valuable public property as in the Boboli gardens, in beautiful and artistic Florence! Most of the many statues within reach of the hand are mutilated; all that can be got at by the pencil are scrawled over with names; yet many are considered valuable works of art. The Boboli Gardens contain also a botanic garden, in which the larger kinds of trees were, after a good old fashion, planted in beds about the width of those frequently employed for Asparagus. This, however, does not rob them of all interest. There are huge Orangeries, filled with plants destined for the open air in summer; but, though fine as a promenade, and commanding fine views of the city and its surroundings, it has few of the charms that a well-designed public garden should possess. The wealthier residents of Florence and its environs are more devoted to gardening; and there are some rich collections and interesting gardens. Among these, none is more worthy of a short description than that of Prince Demidoff,

St. Donato.

Here, though the outdoor garden is large and well-planted, the interest centres in the house-plants, of which there is a very rich collection, and, I think, the best grown I have ever seen in any private garden on the Continent. It differs, however, greatly from rich collections with us in the arrangement. An enormous range of cool and intermediate houses, placed end to end, and communicating with each other, is arranged throughout with the most exquisite taste, applied to the very best materials in the way of fine-foliaged and choicest flowering plants. The roofs and sides of the buildings, pots, &c., and all other objectionable, if necessary, surfaces, are so successfully concealed, that one sees only tortuous vistas, shaded by tropical leaves, and bright with flowers, the vegetation and flowers varying as one goes from house to house. Nothing could well exceed the interest and the beauty of the scene in the eyes of a lover of plants; indeed, the general effect is so striking that during one visit there is little time to notice many rare and finely grown specimens. One huge example of a fine plant, sometimes called the Alexandrine Laurel (*Ruscus racemosus*), cannot, however, be passed by thus, as it rises to a height of 20 feet, while drooping from every point are superb leaves. This specimen is an example of bold, as well as successful, culture; the plant, an uncommon one, is usually only seen well-grown when planted out, as in the College Gardens at Dublin; but here it is grown in a huge tub, and as some unusual means of supporting the strong shoots and heavy leaves was required, a trellis, over 20 feet high, with a small mast in the centre to support it, was made, and from this it droops as gracefully as from a pillar or cross-beam. The specimen is about forty-five years old. This plant deserves to be grown wherever there are large cool and intermediate houses to embellish. The back walls of all the cool houses here are very well covered by Camellias, a practice worth adopting generally, as, apart from the beauty of the flowers, the glossy leaves of these plants furnish a wall so admirably at all seasons. The practice of training Banksian Roses and other climbing plants round the stems of trees, is not uncommon in Florentine gardens; and, in the houses here, there is a modification of it not without merit. Climbers, such as Bignonias, are trained round the stems of tall Dracænas and the like; good cultivators will probably smile at the

practice; but, nevertheless, these little attempts to give a natural grace to cultivated plants deserve a word of praise. Among the plants best represented in the garden are the Australian Proteads, which form a collection of which any botanic garden might be proud. A plant of *Dasyliirion longifolium* here is so old that it has a bark like Cork tree. In the grounds a plant of the Weeping Cedar (*Hegeli*) is the most striking Conifer to English eyes, though the Red-wood of California seems to grow as well here as home. This Cedar deserves a place in every collection of Conifers, especially in the home of evergreens—England. The fine evergreen Hawthorn, *Cratægus* or *Photinia serrulata*, is a great ornament of the grounds, as it is of many in Italy, growing from 10 to 25 feet high, and generally showing among its large green leaves a good many that have faded off to reddish crimson. This gives the shrub a most striking appearance; later on it is covered with large trusses of flowers.

Venice.

This fair city may be said to be rooted on an Oak forest (piles), but they, like all the marble and the stone, and, indeed everything else, had to be carried from far beyond the bitter marsh which, prairie-like, bounds the shallow waters, and on which nothing more precious than Rushes or sea-shore weeds flourishes. With every house on piles, he is hopeful, indeed, who expects any gardening interest here, yet small courts and spots of made-ground beside some of the palaces are converted into miniature gardens, and one of the most tastefully-disposed and, in every way, pretty city gardens I have seen is that of Count Popadopoli, in Venice. On entering it, a pretty open lawn of considerable extent forms the foreground to a living picture of many graceful groups and masses of trees and shrubs. The lawn itself, of a deep rich green—to which our English eyes are not accustomed—is a novelty. It is wholly composed of a Grass-like plant, called *Convallaria japonica*, in Italian gardens; in ours, where, however, it is seldom seen out of botanical collections, it is named *Ophiopogon japonicus*. The Italians say it is the best plant they have for forming lawns; or, rather, for surfacing the earth with verdure, for assuredly it would not stand the test of a garden party. However, lawns composed of one plant only can never be used as carpets, and it is something where lawns of turf cannot be had to have a plant that may be relied on to mantle the earth with green at all seasons. This the *Convallaria* does, and this Venice garden did not show a square yard of bare earth anywhere over its two acres of surface. It was, therefore, much more agreeable to the eye than those gardens in which continual digging always leaves a large extent of surface bare and brown. The *Convallaria* is seldom or never cut in or cut down, and will endure four or five years in good condition. For English gardens or pleasure-grounds this plant may be recommended as one that does thoroughly well beneath trees in poor sandy or dry ground. It grows from 4 to 6 inches high, and may be had in quantity from Italian nurserymen. This garden, like all the houses, is, of course, formed within a wall of piles, and over 50,000 cubic yards of soil, sand, rubbish, and mud were used to make it. On this some forms of vegetation thrive, particularly the Aleppo Pine (*Pinus halepensis*). This has stood when all other Pines failed here, which should be noted by those interested in sea-side trees. The finest evergreen shrub here is *Euonymus japonicus*, so valued in England. It attains a height of 12 feet, and is one of the best evergreens for sea-shore gardens. The Funereal Cypress is the most graceful tree; it, too, is not averse to the shore, and Hollies do capitally, and so does the Loquat; *Sterculia platanifolia* also forms a fine tree here. Well-stored, however, as this garden is with plants, both indoors and out, its main charm is in the design. Towards the back part of the open sun-lawn are the varied masses and groups of trees and shrubs, and, behind these again, almost hidden from the main point of view, a winding walk, bordered everywhere throughout its length with *Convallaria* turf, which here and there spreads in a little lawn, on which Yuccas, tree Pæonies, Spiræas, or Ferns are grouped or dotted. Hardy Ferns, placed here and there among the Grass, in half-shaded places, had a good effect. There were edgings of the common European and Ivy-leaved

Cyclamens, which abound in the woods in Italy, and which would thrive quite as well in our own gardens, if it were the fashion to plant them therein. Thus, between the margins of the lawn and the fringes of the side-walks, there was ample room to place every specimen, so that it could both attain full size, and be seen to advantage, while the confines of the garden were curtailed by judicious planting, and the effect of the whole was most pleasing from the open sunny centre, giving one the opportunity of enjoying and understanding the picture as a whole—a satisfaction always denied to us in the maze-like garden, be it large or small. There is a botanic garden in Venice, but a very small and poor one, now turned over to a nurseryman, who is permitted to repay himself by the sale of plants—a paltry arrangement for a city of marble palaces and churches. Such public gardens or promenades, as there are on the Lido, are poor in character and badly kept, unlike those of Genoa and Florence. It is pleasant to witness, here and there, from the water streets such evidences of gardening under difficulties as those shown in the illustration (see p. 357). In a small court here I noticed an enormous plant of the fragrant *Pittosporum Tobira*, 20 feet high, and about as much through.

A Verona Garden.

There is a garden at Verona not included, generally, among the famous ones of Italy which will repay a visit. The Giusti Gardens at Verona have no plant treasures not common to most Italian gardens, but they contain, what is probably the noblest grove of Cypresses existing, and this distinguishes them, as Bushey Park is distinguished for its Horse Chestnuts, or Warwickshire for its Oaks. Immediately on entering, one is amazed to see an avenue of Cypresses shooting up almost as high as the Giant Californian Pines, yet much slenderer in spread of branches than Lombardy Poplars. One of the first trees met with is 120 feet high, tapering gradually as a Grass stem, waving gracefully in the Alpine air, yet the stem is straight as a needle throughout, and the point rising far into the sky like a wand broken into leaf. The garden occupies a very abrupt slope, a little below the base of which the avenue begins, and, as it rises on the hill-side, one sees the trees from various points of view, in nearly every instance remarkable for their great height and perfect health; one specimen is 125 feet high. Most of the trees are the common Italian Cypress, *C. sempervirens*; but, as if to contrast with the common and most valuable form, there is, also, near at hand, a huge specimen of the more spreading variety (*horizontalis*). Above the avenue and on the top of the steep hill are other Cypresses of the same kind; from the base of these one can look down on the slender spires rising from below, so that the trees seem to assume a new aspect at every step. The steep hill, probably, has helped the trees much, for, northwards, the silvery heads of the Tyrolean Alps seem quite near. The effect of the whole is beautiful in a high degree to the lover of trees. The peculiar and striking aspect of the garden is wholly owing to the Giant Cypresses; the other usual elements of Italian gardening are in the Giusti gardens, but they have no more to do with its broad effect on the visitor than the flooring has to do with that of York Minster. Apart from suggesting the desirability of judiciously planting this beautiful tree, the Giusti gardens convey a lesson as to planting, with a view of showing the full beauty and character of a tree. The varied masses of contrasted individual forms, seen in well-planted gardens, is a great improvement on the monotony so common, but more than this is often wanted. It would be difficult to find a garden with a hundred kinds of developed trees more impressive than this with one. The forms in mixed masses neutralise each other to some extent, or rather prevent the eye from fully enjoying the highest expression of any one fine form. To show a fine tree in the completest manner, we must plant an isolated group of it. Such things may not be in small places, but they deserve attention from those planting in parks, wide lawns, public gardens, and especially arboreta. This plan should, above all things, be carried out where the conditions suit a tree, and is a species considered of much importance. Many of the most valuable trees of northern and temperate countries, from the Olive to the Cedar of Lebanon, vary greatly in form, and it is by the grouping system that this variation will be seen to

most advantage in plantations. As to imparting character to a given spot, the mixed system is, of course, quite inferior to skilful grouping. This subject also suggests a comforting reflection for those whose soil or climate forbids the growth of many trees. A very few kinds fully developed, and so placed as to well show their size and beauty, may afford far finer sylvan pictures than a host of kinds arranged on the general mixture principle.

Genoa.

There is a curious garden at Genoa, that of the Villa Pallavicini, which well shows some diverse features of Italian gardening. It is on one of those steep hills which overlook the sea; it occupies a considerable space, for the most part covered with the native Evergreen Oak, through which many shady walks are made. These wind up the woody slope, and open here and there into little glades, embellished in various ways. For the greater part of its space, it is not laid out in what is called the Italian style; though there are the usual, and, on such slopes as this, the necessary terraces near the house. After these, however, the shady woods, with their native Oaks and Pines, and numerous wild Ferns and streamlets, and their many different peeps at the blue sea beneath, are refreshing. There is much to admire, were it not for the introduction of puerilities that might, perhaps, be in place in a tea-garden or in a rollicking play-ground, but not in a true garden. Sundry grottoes met with are arranged so as to syringe the visitor with water in various ways; and, as he escapes by the only open path, other cleverly-arranged water-jets attack him at every point. Imagine such a *bêtise* in a garden rich with plants, and which, if it only possessed those native to the spot, would be lovely! There are half-a-dozen different contrivances, in different spots, for squirting water in this manner! However, here is an experimental plantation of Palms, and the larger kinds of succulent plants, that have been planted in the open ground for some years, and which compensates us for this infantile fooling. Here we notice that *Agave Salmiani* is much more massive and stately in port than the common American *Agave*, fine as that is in Italy. *Cocos campestris*, *Corypha australis*, *Cycas revoluta*, *Dasyllirion* in variety, and many species of *Agave*; presently masses of our greenhouse *Azaleas* are seen in bloom; and soon we come to a knoll of Pines and Oaks, where the golden light has some difficulty in penetrating; and here are sarcophagi, a warrior's tomb, &c.—an ancient cemetery, in fact. Some antique sarcophagi, perhaps? or, it may be, the tombs of the owner's ancestors? Nothing of the kind—it is all artificial! Presently an Egyptian obelisk is seen, reminding one of some of those at Rome, but on getting nearer we find it is of terra-cotta! After this we ought to be grateful that the trees, too, are not artificial. Happily, a little way off, by the streamlet, there are masses of Maiden-hair Fern; there are plenty of Camellias, and other flowers (greenhouse ones with us) to soften matters a little. Passing by these, we soon arrive at a stalactite cave of distressing gloom and dimensions, after wandering through which a boatman is discovered, who ferries us through another tortuous winding or two of the cave, and soon ushers us into the full sun in a small lake, with marble statuary and fountain, and round its margin a pretty flower-garden. Even this, however, like much of the place, suffers from being too much "cut up" and frittered away by small temples and tortuosities of various kinds. A Camphor tree in this garden is very fine, almost as handsome as a Plane in the spread of its branches. There is also a fine Cork tree, said to be the finest in Italy, but it is not half the size of the trees at Caserta, near Naples, nor quite so good as a tree at Linton Park, in Kent. There is a very remarkable specimen of *Cycas revoluta* planted out for some years, with a clear stem of 4 feet, which shows that this plant will flourish in a cooler temperature than is generally supposed. The garden, notwithstanding the objectionable features spoken of, is one of the best in Italy; its best aspects, however, rather arising from the beauty of the position and the natural woods which occur on it, than from the gardening. There is a noble greenhouse shrub cultivated here, and in many Italian gardens, called *Enkyanthus quinque-florus*, reminding one of *Kalmia latifolia* in the flower, but a

finer shrub. It is abundantly grown in tubs for placing in the open air in summer, and flowers very handsomely in spring. It well deserves extensive culture for conservatory decoration. There are some effective little arrangements in the public gardens at Genoa; and here I noticed, for the first time, our English Stonecrop (*Sedum anglicum*) used to surface the ground instead of turf. This it did very well indeed, and the effect of the fine *Dasyliirions* and dwarf Palms was much heightened by their springing from a surface everywhere verdant. Several of the dwarf green Stonecrops might be used with advantage in this way where turf will not grow well.

THE ARBORETUM.

SEA-SIDE PLANTING.

It certainly never would have occurred to me that trees and shrubs should be planted close down to an exposed sea-shore for any purpose except for shelter, and it was under this supposition that my last note was written. Mr. Scott, however, appears to plant in positions of this character wholly for ornamental purposes; at least, this is the only object which can be gained by planting such shrubs as he mentions. The hardiness of these close to the sea is quite in accordance with our experience, with the indispensable proviso that there must be an outer hedge, or strip of storm-proof plants. Provide this, and many ornamental plants will grow kindly. There is, after all, only one tree which we find valuable both for ornament and shelter in extreme exposure to the sea, and that is the *Pinus Pinaster* and its smaller variety *maritima*. Mr. Scott says it will not thrive on clay. More is the pity; but let me strongly recommend it to all who plant for shelter on a free soil near the sea. It seems to delight in the blast; and, although sometimes tardy of growth at first, and even frequently "knead" when it does get a start, and although limb after limb may be torn from it in high gales, still, it conquers in the end, thrusts out sturdy limbs to windward, and (this appears its peculiarity as compared with all other Conifers) it never loses the deep rich green of its foliage. What is the value of the timber I know not, but wood of any sort cannot be grown for much profit close to an exposed coast. Further inland it grows to a considerable size. I have to day measured one, within a mile of the sea, 10 feet in circumference at a height of 4 feet. One more point in its favour, and I have done eulogising the *Pinaster*. The huge cones, which it bears in abundance, make capital fuel. Put half-a-dozen into a sulky fire, and you have a blaze in five minutes. It is a tree which does not bear drawing up, as most Conifers do. Unless the breeze has free access to all parts of it, the rugged bark will rot, and the whole tree decay. As for the Bramble, which Mr. Scott says truly is "one of the most persistent sea-side plants we have," it cannot be made to grow freely where it has not appeared spontaneously. We have sent from the woods here sacks of Bramble roots to Roxburghshire at the request of friends who envy the matchless game-covert which they afford, but the result was not encouraging. Has Mr. Scott tried the *Cupressus macrocarpa*? It thrives excellently in sea air, and grows rapidly, though I have never seen it tried close to an exposed coast; but at Castle Kennedy there are fine masses of it, in a severe exposure, doing very well. With a little shelter we find it invaluable.

SALMONICEPS.

TREES AND SHRUBS IN THE CHANNEL ISLANDS.

I VISITED the Channel Islands in January last, and was surprised to find, at this early season of the year, so many trees and shrubs flowering in the parterres and pleasure-grounds of these sheltered islands. The climate and temperature, indeed, seemed just suited to the requirements of the strangers. I noticed interesting plants in full flower in January in Guernsey, Jersey, and Sark, such as we cultivate ordinarily under glass. First, I would speak of the Australian introductions. Large masses of the graceful *Acacia dealbata*, with tree-like boles and beautiful racemes of yellow bloom, gave great beauty to winter-lawns. The thickness of some of the trees was considerable, and showed many years of growth. *Acacia Mela-*

noxydon, with its bright green phyllodia, was also a veritable tree; its little globes of yellow blooms were not yet expanded though fully formed. *Hakea rosmarinifolia*, covered with beautiful pink blossoms, was exceedingly attractive, and seemed perfectly at home in Guernsey. It is one of the *Proteaceæ*. *Metrosideros speciosa*, one of the *Myrtaceæ*, had its heads well swollen, and giving good promise of bloom in April. I noticed also fine shrubs of *Aster argyrophyllus*. It is musk-scented, and its composite flowers are white. It is a native of Van Dieman's Land. Conifers seem to take kindly to the Channel Islands. *Dacrydium cupressinum*, a native of New Zealand, and also *Phyllocladus trichomanoides*, a fern-leaved Conifer, were growing most vigorously at Rozel, on the north coast of Jersey. The boles showed several years of growth. *Fitzroya patagonica*, a graceful drooping evergreen, seemed to luxuriate in the climate of Jersey, growing not far from another pendent Conifer (*Abies Morinda*), a native, I believe, of the northern mountain-ranges of India. Lastly, *Araucaria brasiliana* put in a very healthy appearance in Mr. Carré's grounds, at Valnord, in Guernsey. It is more graceful and of looser habit than its ally on the western coast of South America, *Araucaria imbricata*. *Rhododendron arboreum* showed a perfect blaze of bloom in the middle of January; and I noticed, likewise, at Rozel, *Rhododendron Thomsonii*, *Edgworthii*, and *formosum*, giving promise of future bloom, without other protection than surrounding evergreen vegetation; and the same remark may apply to *Rhododendron cinnamomeum*, a white-flowered species from Nepal. The beautiful Gum trees of Australia give great effect to lawns and pleasure-grounds. I observed among them *Eucalyptus pendula* and *piperita*; and, though rare, *E. pulverulenta* thrives well, I learn, in Guernsey. They belong to the *Myrtaceæ*, and, like them, their flowers are dense masses of stamens. The *Escallonias*, from the west coast of South America, are very ornamental, and seem to acclimatise readily in gardens near the coast, being covered with their lovely flowers in mid-winter. I noticed several species, but *E. macrantha*, a native of Chiloe, far surpasses the rest in beauty. Large trees of *Euonymus japonicus*, with their shining evergreen foliage, were literally covered with their rich coral-red fruits. Two New Zealand *Cordylines*—*australis* and *indivisa*—ornamented the lawn of Mr. Carré's house, and appeared quite acclimatised, having stood fifteen winters without protection or shelter. They, alone, are worth a visit. Three kinds of *Pittosporum* flourish as shrubs in the Channel Islands, and attain fair proportions; these are *Pittosporum Tobira*, *Mayi*, and *Novæ Zealandiæ*; the first was in full bloom in January. *Bambusa gracilis* and *arundinacea* were flourishing vigorously in Guernsey without the slightest shelter. They had attained the height of upwards of 15 feet. Dense masses of the Tree Heath (*Erica arborea*) were everywhere abundant in the Channel Islands. Every cottage-garden had its Heath shrub in bud or flower, according to its exposure. I was much surprised to see *Lapageria rosea*, a native of the island of Chiloe, which in England we treat as a greenhouse plant, still lingering in bloom in the open air on the first day of the new year; it had borne a profusion of blossoms during the autumn. By the side of the fish-ponds at the Seigneurie, in Sark, I observed a curious plant, with large rough leaves and a spadix dotted over with red seeds. This was *Gunnera scabra*, found by Darwin growing on the sandstone cliffs of Chiloe, a coarse-growing plant, whose leaves, he says, sometimes measured 6 feet in diameter.

PETER INCHBALD.

The Lodge, Hovingham, April, 1874.

PREPARATION OF GROUND FOR TREE-PLANTING

By JOHN DARLING.

THE history of arboriculture in our country in former times has too often been but a record of short-sighted economy. Except, perhaps, in the vicinity of the mansion-house, where shelter and ornament compelled the appropriation of good soil to the growth of timber, it was only such portions of the estate as were totally unfit for agricultural purposes, or even pasturage, that were devoted to the growth of trees, and not only was the poorest soil considered sufficient, but no care was evinced to remedy its defects. It seldom seemed to be a matter of consideration to make the growth of timber profitable. I

time that the maxim should be applied to this which has been applied to many other departments of national industry, "What is worth doing, is worth doing well;" and, since the produce of the forest requires a lengthened period of time to arrive at maturity, it is all the more necessary that a reliable foundation should be laid to sustain the hopes of a future remuneration. Perhaps the fear of not realising a return in their lifetime for the necessary outlay has deterred many proprietors from laying down their plantations in such a manner as they could have wished; but such a motive is surely unworthy, and can have no weight at the present day, when timber,

almost all its stages of growth, is such a valuable commodity; and since it has hitherto been, and most likely will still be the case, that, except for the purposes of shelter or ornament only, the value of an inferior quality will be devoted to the growth of timber, it is the more necessary that pains be taken to make the most of the material. In making a few remarks on the preparation of ground for planting, we will state them in the following order: 1. Clearing the ground; 2. Fencing; 3. Making roads; 4. Drainage; 5. Making pits.

Clearing the Ground.

On the greater part of land which has not been used for agricultural purposes there will be much matter detrimental to the growth of young trees if left untouched. Heath, furze, broom, and other coarse ligneous plants must all be removed, that there may be nothing to impede the full development of the trees. We would prefer burning, as the surest and most expeditious mode of checking the growth of Heath, where it can be performed with safety, and, where danger is apprehended, the fire can be stopped by turning over a line of sods across the direction of the flame. When burning will not eradicate Heath, but will so check its growth that, by the time it recovers, the trees will be beyond all danger of injury from it. Were it not that, where the Heath is rank, the young trees might be choked by it, we do not consider it otherwise experimental. Broom, if old, can easily be destroyed by cutting over the ground; but, if young, the stems will be covered with eyes, and such cutting will only induce a more rapid growth; therefore, it is better necessary to take such up by the roots. Whins are in this respect more detrimental to the growth of plantations than other woody plants, as well as more difficult to eradicate, and, where

they grow close, simply cutting over above ground is altogether lost labour. The greatest care should therefore be taken to remove them by the roots, and any necessary expense incurred by this operation will be amply repaid in the smaller amount of labour required in the future management of the plantation. Raspberries and Brambles will sometimes, especially on gravelly soils, be found a great nuisance. It is next to impossible to eradicate these; perhaps the best plan is to cut the canes successively till the young trees are beyond reach of injury from them. All other spontaneous growths, such as Birch, Hazel, &c., which, in almost all cases, will be entirely unworthy of a place in

the new plantation, should be cleaned off, so that not only the growth of the young trees may not be impeded, but also that subsequent operations on the ground may have as little interruption as possible. In certain localities, the clearings may be of value as firewood, and may somewhat lessen the expense of preparation. If such is not the case, let them be collected into heaps and burned, and the ashes blended with the soil.

Fencing.

We consider fencing the next indispensable operation in the preparation of ground for planting. It ought never to be considered a point of minor importance, but ought to be attended to immediately after the clearing of the ground, lest the future operations of making roads, drainage, and pitting might suffer damage from stray cattle, or other causes. In selecting a fence for a plantation the first object to be aimed at is durability; next, the least possible ultimate expense. In some cases a necessity for ornament may guide the selection, but in all other cases, and where the requisite material can be obtained, we would prefer a stone dike, both for durability

and ultimate cheapness. In many situations, however, it may be difficult, or altogether impossible, to obtain stones; in such cases a wire railing with Larch posts offers a good substitute; and, if economical considerations extend beyond the present, a little extra labour and expense in charring the ends of the posts or dipping them into some solution to resist the decomposition which inevitably ensues from contact with the soil, and coating the part exposed to the atmosphere with boiling coal tar, or other solution suitable for the purpose, will eventually remunerate, by increasing the durability of the paling; but, where cheapness guides the choice, a dike and ditch, with a hedge of Whins on the top—the materials of which the dike is built being taken

Court-yard gardening in Venice (see p. 355).

from the outside—will form a fence of considerable efficiency, although this is, at best, but a clumsy and not very certain protection to the plantation, especially for the first three or four years, when the trees are young. In such places as require an ornamental fence, a hedge is no doubt the most suitable; Beech, Hornbeam, Holly, and Thorn are the more common materials, but the two former do not offer such resistance to animals as may, in many instances, be desirable; the two latter will, in time, make an excellent fence, especially Thorn, which offers greater resistance to animals than Holly, and is also much cheaper. Holly, being an evergreen, may be preferred in some instances; still, as a general rule, we would prefer Thorn. Hedges, however, require to be protected a number of years by a paling. Care should be taken to select such material, and give it such treatment, as will make the paling last till the hedge is a sufficient fence. Hedges also entail considerable expense, not in the original laying down merely, for continued yearly attention must be paid to them; but they amply repay it all by the charm they give to the landscape.

Making Roads.

In a highly civilised and commercial country, such as this, time is of great value. It ought, therefore, to be the object of the planter to provide the greatest possible facilities for the removal of felled timber, as such facilities will greatly enhance its value. In former times this was never thought of till the trees were of large growth, when gaps were made in the fences, if any fences existed, and avenues cut through the wood. This must often have been at hazard, and the soil was in all cases unfit for bearing the conveyance of heavy burdens, added to which, the stumps and roots of the cut trees combined to form a road as execrable as any in the backwoods of Canada; nor are roads needful for the removal of felled timber only, but for the protection of the plantation when, in a growing state, they are highly advantageous, and also for preventing the necessity of removing prunings or thinnings over the fences. All these considerations enforce the necessity of forming roads at the commencement of operations for planting. We are not prepared to specify the particular distances at which they should be made; this must be regulated by the extent, plan, and situation of the plantation, keeping always in view the economy of labour in conveying timber of large growth to the roads, taking advantage also of level tracts or gentle declivities leading to the outside of the plantation, and avoiding, if possible, steep ascents, thus lessening, as far as possible, the amount of animal labour required. In forming the roads, particular attention must be paid to drainage, especially where the soil is not hard. In most cases a drain on each side, with the material taken from them laid over the centre of the road, so as to give it a convex form and throw the surface water into the ditches, will be sufficient. When the inclination of the ground renders it necessary to provide cross drains, they should be built with stone, and have very strong stone covers. We would not be inclined to lay down a road less than 7 yards in width, so that loaded carts might pass with ease without injuring the edges of the ditches, and also to give room for loading and turning carts. A road made in this manner when a plantation is laid down will, by the time the timber is fit for cutting, be in a state to bear any ordinary load.

Drainage.

The next operation is drainage, which, except on very dry soil, is all but indispensable. In proceeding with this, it is necessary to examine the inclination of the ground that the main drains may have the advantage of all the fall possible. The distance of the main drains from each other must be regulated by the nature of the ground. If level, or nearly so, the small drains cannot be expected to be effective farther than from 150 to 200 yards; but, where considerable declivities exist they will act farther, and the mains should be carried along the natural hollows. As a general rule, small drains should not be less than 2 feet deep, and, if the fall permit, an additional 6 inches would make them much more effective. If the ground is very wet, we would not be inclined to place them farther apart than from 24 to 30 feet. Where the ground is not so wet, the distance may be increased by 6 or 9 feet. To keep the drains clear, the mains require to be from 4 to 6 inches deeper, and where a natural fall does not exist to carry off the water from the mains, no labour must be spared to secure it. It sometimes happens that very steep ground requires to be drained—in such cases, instead of leading the drains directly down the declivity, we would carry them obliquely across, taking care that sufficient fall is secured to carry off the water speedily. The propriety of this mode will be apparent when we consider that the particles of water in the soil of a deep declivity will have a greater tendency to settle down the declivity than sideways into a drain running straight to the bottom. A drain carried obliquely across the face of the declivity catches all the moisture as it percolates downwards, and, if a quick fall is secured, the water will

have no inducement to penetrate into the soil below the drain, but will run off and secure a perfect drainage; whereas drains cut straight down the declivity would do little more than carry off the rain water which might fall into them. The advantage of judicious draining must be apparent to even the most casual observer. Stagnant water about the roots of the young trees prevents that development of the roots necessary for their healthy growth—hence, on undrained ground, young trees have a stunted unhealthy appearance, make little progress, and in many cases die out altogether. It may also frequently be noticed, on ground where the drains are too far apart, or too shallow, that the trees by the sides of the drains are thriving and growing rapidly, while in the centre between the drains they have the stunted appearance peculiar to undrained ground.

Making Pits.

This operation is necessary for all hardwood trees. In ordinary cases, slit planting is sufficient for trees of the Fir tribe, but hardwood trees will not succeed so well unless better pulverised soil is provided than can be got by slit planting. For trees of the size ordinarily got from the nursery, pits 2 feet in width, and depth regulated by the nature of soil, will be sufficient. The pits should be dug some months previous to the time of planting, that the action of the weather may pulverise the soil, and make it more congenial to the tender roots of the young plants. Ordinary-sized hardwood plants, on gravelly soil especially with a southern exposure, will require pits of much larger dimensions. In such situations pits of the ordinary size will retain too little moisture to sustain the young trees, whereas if a greater area and depth of the soil is loosened, and the stones removed, the original channels through which the water percolated are disturbed, and far greater power given to retain moisture. In such situations, Firs especially if intended for standards, would require to be treated similarly, and even in ordinary soil, if Firs are of larger size than common, they will require pits prepared for them.—*Scottish Arboricultural Society's Transactions.*

THE FRUIT GARDEN.

OUR SHORTCOMINGS IN HARDY FRUIT CULTURE.

If a foreigner, unacquainted with the fruit-growing capabilities of this country, was told that American Apples sell at four pence each in Covent Garden Market in January, he would at once say, "These English must be fond of Apples, have plenty of money, and their country is incapable of growing this fruit. But, if, in addition, he was informed that there are few countries better suited to Apple culture, and, moreover, that the last year was a moderately good Apple year, he must come to the conclusion that our Apple culture is nothing to boast of. There are several causes which have brought about this state of things. We are less provident than some of our neighbours. The really useful, except in matters of the first magnitude, is not studied as it deserves to be. The general prosperity of the country causes us to look with indifference upon anything that at first sight has an appearance of comparatively little importance. The large land owners and occupiers have never been alive to their own interests, or to the requirements of the country, in the matter of fruit. And yet it does not require much consideration to convince anyone that the subject, whether looked at from a financial point of view, or in relation to providing a most necessary article of food for the people, is anything but a matter of little importance. If we except the cider-producing districts, and the market growers in the immediate vicinity of some of the large towns, comparative nothing is done throughout the length and breadth of the kingdom in providing for the people this most wholesome and useful of all fruits. Even in many private establishments considerable pretensions, not enough are grown to supply the wants. The occupier of a farm rarely thinks of planting fruit-tree; his agreement generally binds him in the strictest manner from ever lopping a branch from a hedgerow-tree; yet he may with impunity grub up an old orchard, without any obligation of planting a new one. The absence of a lease, and consequent uncertainty of tenure, with no certainty of reimbursement for permanent improvements, naturally causes indifference as to a crop that he is uncertain of ever reaping any benefit from. Benevolent and political economists vie with each other in schemes for the improvement of the labourer in rural districts, by providing him with a bett

ttage and garden for the growth of his Potatoes and Cabbages; it, in pulling down his old abode, the tree on the gable, which did something considerable towards paying the rent, comes down along with it, and there is often little or nothing in the shape of instruction, or assistance, to induce or enable him to supply its place. Yet this is a means by which those who interest themselves in the improvement of the country labourer, might do much for his benefit directly, as well as spreading a knowledge and taste for a pursuit in which we are, as a nation, behind many other countries. Even village horticultural societies, whose objects are to spread a taste for gardening amongst the poor, do little comparatively to encourage the cultivation of the more useful species of fruits. So far as the cultivation of fruits, more especially the Apple, which would be of more importance than all others which we grow together, I see little chance of their being produced in such quantities as to bring the price within the reach of all, unless the subject is taken up by the great land owners of the country, and by their planting and urging upon their tenantry the importance of the little attention necessary for the welling of the trees. The quantity of Apples that might be grown in the hedgerows without injury to other cultivated crops, is incalculable. Against this I have heard it urged that it would be impossible to prevent marauding; that every boy in a parish would become an Apple pilferer. If only a few trees were planted in a district, to some extent this might cur; but, if this system of culture were carried out to the extent it ought to be, such would not be the case. Again, it is urged, if Apples were produced in such quantities, they would not be worth the trouble of gathering. Those who argue thus, forget, or are ignorant, that the land through the kingdom, is not all suited to the growth of this fruit; probably, not more than one fourth might be calculated upon as suitable for its culture; and, in these, as with other things, a considerable reduction in price, would increase the consumption, to an incalculable extent.

Another fruit, the Damson—particularly the Yorkshire variety—is especially suited for hedgerow planting. It is sturdy, a good cropper, and the tree, from its upright habit of growth, gets out of the reach of cattle. With Apples, for the purposes under consideration, it would be necessary to select such kinds as were found to succeed well in each respective neighbourhood; they would also require to be specially prepared, by being grafted higher than for ordinary use. They would also be strong upright growers, so as to be out of the reach of cattle, which are excessively fond of this fruit. Fortunately, there is no lack of good varieties, of which some will do well in one locality, some in another, and others will succeed almost in any situation where Apples will grow. The great number of varieties of this fruit in cultivation have checked the extended culture by the disappointment many of them have caused. Hundreds of them are not worth growing, either as to the quality or quantity of the crop they produce, as compared with a limited number of sorts of sterling merit that grow well in most parts of the kingdom, and are everything that can be desired in the quality, quantity, and keeping properties of their fruit. New varieties every year keep making their appearance, but few of them, when they come to be tested, growing side by side with approved kinds already well known, are found to possess a single quality superior to the old ones. There is one most essential property capable of development in new varieties that raisers appear to lose sight of completely, that is, the production of a race of late-flowering kinds that do not blossom until the season is so far advanced as to materially lessen the danger from frosts. What we want is a thoroughly good representative of the different sections of the kingdom, with the late-flowering disposition of the Court Pendu Plat variety. This Apple, as is well known amongst hardy fruit growers, is quite three weeks later in both flowering and leafing than other kinds; it is also good for dessert, a fair keeper, and a handsome fruit. Anyone who could raise half-a-dozen sorts of dessert Apples with the late-flowering habit of Court Pendu Plat, combined with the quality of fruit and free-bearing disposition of Irish Peach, Burgil, Cox's Orange Pippin, Ribstone Pippin, Sykehouse Dessert, and Sturmer Pippin (these should be associated with culinary sorts having this late-flowering habit and the general

merits of Lord Suffield, Blenheim Pippin, Alfriston, Dumelow's Seedling, Yorkshire Greening, and French Crab); anyone, I repeat, accomplishing this would deserve honours equal to any ever conferred on an individual connected with horticultural pursuits, as well as something more substantial. But, with the above, or any other possible selection, there are some that will not succeed on all soils; and, in planting fruits, especially Apples and Pears, it is always best to ascertain what sorts are found to succeed best in the neighbourhood. Even for the supply of a private family, it is much better to restrict the number of varieties grown to a dozen kinds that are found to do well, than to grow half a hundred, many of which will either grow or bear indifferently, and not have distinctive merits enough to make them worth cultivating. The practice of the market growers, in any part of the country, is much sounder than that of most gardeners in private establishments. The former confine themselves to the growth of such sorts as are found to succeed best in the locality; the latter generally grow four times the number of kinds, either of use or required, even if all would succeed well. For instance, the American-grown Newtown Pippins are magnificent Apples of surpassing excellence; whilst the same variety grown in any part of England, that I have seen, could not possibly be recognised, were it not that they retain the black spots on the skin peculiar to this variety. The same holds good with Pears. What is the use of growing twenty sorts that all ripen in November, when a third of the number may be selected that possess all the merits of the rest? Another very common mistake is to plant the best, and often tender kinds, in districts wholly unsuited to any but strong-constituted second-rate sorts. In Lancashire, the better kinds of Apples and Pears do not succeed, except near the coast, and even where these do well and bring good prices, the market growers find it more advantageous to confine their practice to good-constituted, free-bearing, second-rate sorts. An acquaintance of mine who lived some half-a-dozen miles from the coast, used to grow acres of Hessel Pears; the crops he got were enormous, but instead of the trees being planted in the ordinary fashion, they were grown on ridges; strong stakes were driven down in rows, the trees were tied to them, spreading their roots out on the surface, and then covering them to the requisite depth from the alleys. The ridges ran north and south, with treble the distance between the rows that existed between the trees. This was to admit of ridge Cucumbers being grown on alternate ridges, the Pears sheltering them from the strong west winds coming off the Channel, that otherwise would cut them to atoms. The raisers of new Apples and Pears, I consider, make a mistake in working altogether from the best sorts, that are only suitable for cultivation in the most favoured localities as to soil and climate, and which are only likely to produce varieties suitable for similar situations. Would it not be better to work from free-bearing hardier sorts, that succeed in situations less favoured, with a view to increasing the varieties that succeed in such places? The culinary Apple, Lord Suffield, is evidently a seedling from Keswick Codlin, and, notwithstanding the free-bearing disposition of the latter, how many raisers would ever think of breeding from so common a kind? Yet, Lord Suffield has the merit of thriving freely, and bearing, even in a small state, until its branches are bent to the ground, in situations so unfavourable to Apple culture that not half-a-dozen of even the most common sorts would live; yet, there is probably not a culinary Apple in existence for which the demand is so great for planting, even in good Apple districts, as this variety.

It is a great disappointment, after planting a lot of fruit trees, to find that half of them, when they ought to come into bearing, are so far unsuited to the locality as to be useless; yet this is a common occurrence, arising through a want of knowledge of the kinds adapted to the district. In the selection of Apples, Pears, and Plums for planting, it is usual to divide the kingdom into south, midland, and northern districts; this is generalising far too much. There is scarcely twenty miles of a single county in any direction where very great differences in selection are required to be made, and nothing less than close personal observation, over a series of years, can enable anyone to make a selection suitable for any

given neighbourhood. In the choice of a situation for planting with fruit trees, care should always be taken that it is sufficiently sheltered from the west and north-west winds, as the storms we have from these points are most destructive to the crops on standard trees. Where it is the intention, with orchards or large breadths of land planted with fruit trees, to keep the ground dug, the best practice is to plant the trees one-fourth further apart betwixt the rows than the distance between the trees in the rows; this gives room for a row of Currants or Gooseberries between each row of trees. The bush fruits so planted, frequently escape the effects of frost or cold springs, through the shelter afforded by the trees; and, with Black Currants, the shade is beneficial rather than otherwise.

As to the storing of fruit through the autumn and winter, it too often happens, even in private establishments, where the gardener is expected to produce Apples and Pears in good condition, so long as they are in season, that any sort of a place that can be called a fruit-room is thought good enough for the purpose. Yet, I feel confident that four out of every five of such places are totally unfit for keeping fruit as it ought to be. There is nothing with which I am acquainted that is more susceptible of taint, not only from actual contact, but even from being near anything affected with mould, or, in other ways in a state of decomposition. I have seen the flavour of a fine collection of Apples and Pears completely spoiled by being placed in a fruit-room, the shelves of which had begun slightly to decay. To preserve the natural flavour of these fruits, without imparting anything objectionable to them, as also to keep them from shrivelling, requires the atmosphere of the fruit-room to be balanced to a nicety. It is scarcely possible to place any material over dessert Apples or Pears without affecting their flavour; even Wheat-straw, in the sweetest possible condition, perfectly dry, will frequently spoil the flavour, through the moisture the fruit gives off causing the straw to mould, even so slightly as to be only perceptible by a faint odour. No second-storey apartments are fit for fruit-keeping, being too dry; the best fruit-rooms I have ever met with have been underground; a cellar in a thoroughly dry situation, where a sufficient amount of air could be admitted for a time after the fruit was gathered to dispel the moisture given off from it. I have in such a place often kept Alfriston and Bedfordshire Foundling, plump and in good condition, until the succeeding year's crop was gathered, which is considerably longer than these Apples usually keep. After a dry summer, when all fruits are usually longer before they ripen here, Easter Beurré and Beurré Rance were plump and full flavoured until the middle of May, and Nec Plus Meuris equally good until June. After a wet sunless summer, Easter Beurré sometimes will not ripen; it is often gathered too soon, which has the effect of causing this Pear to be worse to manage in this respect. I accidentally found out a means of remedying this; an old Peach-blind happened to be thrown upon one of the boxes filled with this kind; this was early in the winter, it was not removed until March, when the fruit were in fine condition, plump and soft, others from the same tree being tough, leathery, and unfit for table. Evidently, after dull sunless summers, this variety loses too much water by evaporation when fully exposed, the absence of which prevents the ripening process from taking place. Since then, I have always after such summers covered the fruit in the way described, laying the material three or four thicknesses over them, being very careful to use nothing except linen fabric that has been long exposed to the weather, so that it has not the slightest remaining smell of the size or dressing used in its manufacture. Pears that are kept in drawers made for the purpose and shut up, I have always found to be strongly affected with the odour of the wood. Apples and Pears are frequently kept plump and fresh in appearance long after their natural season for ripening, by covering them with bran, dry sand, or similar materials. Culinary Apples so treated are passable, but dessert fruit, either Apples or Pears, are insipid and worthless. All these materials—bran, dry sand, &c.—possess elements of decomposition, which, in their evolution, are, inevitably, imparted to the fruit; for them, the well-bleached linen alluded to will be found a most satisfactory substitute. T. BAINES.

THE FIG.

COMPARATIVELY few ever taste really choice dried Figs in this country, and, fewer still, green Figs in that perfection which they attain under circumstances favourable to their growth. It is singular that this delicious fruit has never yet received in this country that cultural care which has been given to the Grape and Peach; hence, the fact, that we seldom see it in perfection, and how can it be otherwise, the back wall of a Grapery or Peach-house, being the place usually assigned to it, although it is a fruit that loves cloudless sunshine and the balmy mountain breeze. Mr. Rivers and others have done something to spread a more general taste for this fruit among us. Jewish history tells us, that during ten months of the year fruit was found upon Figs, and that they were of three different sorts, namely, the early Fig, the summer Fig, and the winter Fig; the early Fig ripened towards the end of June, and was the most beautiful and delicious of the season. "One basket had very good Figs and new, even like the Figs that are first ripe," said Jeremiah. And the prophet Hosea uses this beautiful figure regarding them, "I found Israel like Grapes in the wilderness, I saw your fathers as the first ripe in the Fig tree at her first time." The way that this fruit was gathered in Judea is seized upon by Nahum to give expression to one of the most beautiful illustrations in the Bible—"All thy strongholds shall be like Fig trees with first-ripe Figs; if they be shaken they shall even fall into the mouth of the eater." The summer Fig made its appearance in June, when the early fruit began to drop off; it began to ripen in August; unlike the early Fig, they could be kept for a long time. The winter Fig appeared in August, and came to maturity about the end of autumn. After the tree had lost its foliage, if the winter was mild, the fruit was allowed to remain upon the tree until spring, and was then eaten as a dainty; it was larger than the early fruit and darker in colour. We cannot wonder that a fruit, so productive and delicious as the Fig, was seized upon both by prophets and poets in order to give force and expression to their language; for, besides yielding luscious fruit in abundance, the tree afforded a refreshing shade from the fierce rays of the sun—indeed, it was a common practice with the Jews to remain, during the heat of the day, under their Vines and Fig trees. That the Fig tree in Canaan was—as with us—often barren and liable to shed its fruit untimely, we can glean from the Scriptures and other historical works. "Let it alone this year," says the husbandman, "until I dig about it and dung it, if it bear fruit well; and, if not, then, after that thou shalt cut it down." Of the different varieties of this fruit grown in Palestine we know little or nothing; but there is every reason to suppose that they were not numerous. We see, from a notice of this fruit in THE GARDEN (see p. 290) that in the days of Cato only six varieties were known. We also see, from the same notice, what an important place this fruit occupies in the history of other nations besides that of the Jews; but, apart from its historical associations, the Fig has enough in itself to recommend it to a high place amongst dessert fruits. If it bore three successive crops in the open air in Palestine, surely the same result might be attained under glass in this country. But, with us, the places are comparatively few where the Fig may be said to receive the same attention and cultural care as is bestowed upon other choice fruits. A young gardener may be brought up in many of our best places, and yet never have an opportunity of seeing this fruit grown in perfection. It is not necessary to enter into detailed descriptions of the different modes of culture practised in reference to the Fig in England, but there are certain conditions requisite before it can be grown in perfection; that climate has a greater influence in the development of the Fig than soil, I am quite convinced; under glass we have an artificial atmosphere to create, and it rests, in a great measure, with the cultivator whether he so regulates the means at his disposal as to produce fruit of the best quality—an inference which also holds good with regard to all artificially forced fruits. Another essential point in the successful cultivation of the Fig is, a complete command over the roots, this can be done with more facility when they are grown in pots, than when planted out; indeed the pot system has many advantages when properly carried out. The finest Figs which I have ever seen were grown in pots in a house fully exposed to the sun, and where no other

plants of any description were cultivated in the house, the floor was concreted, on which the plants were placed in rows, a prepared compost of stable-dung and leaves was placed round the pots up to the level of their brims, and this, besides yielding a slight-bottom heat kept the pots moist in a house fully exposed to the glare of the sun; the roof, which was iron, was made as low as possible, and culver-shaped; diluted liquid-manure was, occasionally poured upon the floor, and this, as it vaporated, helped to give health and vigour to the plants and to keep them free from the red spider. When the fruit began to drop, a mulching of dried Fern was spread over the compost and from this the Figs were gathered every morning and evening. During two months in mid-winter the plants were allowed to rest in the open air while the house underwent a complete renovation.

BLACK ORANGES.

PARAGRAPHS are going the round of the papers dilating upon an American story to the effect that an extensive Orange-grower in Louisiana has this season produced a fine crop of jet-black Oranges. This *lusus naturee* is described in the transatlantic press as being of a more extraordinary character than that so anxiously sought for among the Dutch florists of the seventeenth century, namely, a "black Tulip"—a phase of the Tulipomania which Alexander Dumas has immortalised in his picturesque romance, "La Tulipe Noire;" more extraordinary, even, than the "coal-black Rose" of the negro ballad. The reported black Oranges are, it must be confessed, a possibility; for though we have not, as yet, a black Rose, we have, at all events, a bright green one—a curious variety of the single Dog Rose—which exhibits no deformity, no abnormal growth, but has regularly-formed delicate green petals, as beautiful and perfect in texture as those which exhibit the tender blush-pink of the typical plant. We have also seen green Dahlias and black Apples. But to return to the black Oranges. Those who have seen the egg of a cassowary may picture to themselves the precise effect produced by the fruit of this new variety, so exactly does the surface of the egg resemble that of the rind of an Orange, while its colour, so unlike that of any other egg, is indisputably black. It certainly does appear within the range of possibility that a seedling Orange tree, from some peculiar constitutional character of the seed, may bear black fruit instead of orange-coloured. The seeds of other plants often produce both flowers and fruits differing in form and colour from those of the parent; and the Orange is, perhaps, the most liable of all well-known plants to produce from seed plants yielding fruits of most unusual and grotesque shape, entirely differing from the spheroidal conformation of the more usual types of the fruit. Yet, no very striking deviations of colour have hitherto occurred. The fruit-rind of even the strangest-looking varieties has constantly presented some tone of yellow, varying from the palest straw-colour, through infinite gradations of green-yellow, full-yellow, and orange-yellow, to the deepest tones of rich golden-orange. It must, therefore, be by a very unusual and striking aberration of physical habit that a positively black-fruited kind has been produced. But this endeavour to account for a singular botanical novelty may, after all, be rendered futile, as applying, perhaps, to a thing which has no existence in reality, for the Yankee dressings up and padding by which it is thought, after the American fashion, to get "laughing gas" out of this asserted freak of nature, as well as political satire, makes the whole thing look rather like an ingenious hoax. For instance, it is suggested, that this strange vagary of plant-life having taken place in Louisiana, in the Orange-groves belonging to Mrs. Beecher Stowe may have been the necessary consequence of her enthusiasm as an Abolitionist, and her intense interest in niggers. It is, moreover, superadded, as a singular corroboration of the foregoing nigger theory, that in the immediately contiguous Orange grounds, still belonging to good southerners, the whole of the fruit remains of the usual rich golden-yellow. That a single tree, bearing black Oranges, might have appeared in the Orange-groves of Mrs. Beecher Stowe (if she have any), or in those of any other proprietor, is certainly possible. It is even possible that a peculiar kind of

blight may have blackened the fruit of a whole district; but when we are told of the black crop ceasing accurately at the boundary line between two properties, we necessarily lose faith in the whole story, and feel that, if black Oranges be indeed a desideratum, that in all probability they will have to be waited for very patiently, and then, perhaps not found, even amongst the most wonderful forms of the "fruits of the future."

OUTDOOR GRAPES.

SOME years ago I planted a border in my garden with Vines, more for the purpose of covering an unsightly mud wall than with the idea of obtaining fruit; but, as the results obtained in this way have very much exceeded my most sanguine expectations, I will relate my experience. The border is mainly composed of brick rubble, old mortar, and ordinary garden soil, and the Vines were planted without any preparation whatever. I selected Esperione, because its foliage becomes so very richly tinted as it is dying off in the autumn, and this has, quite contrary to my expectations, produced some nice crops of fruit, the best clusters of which are certainly eatable, but most valuable for wine making. There are half-a-dozen Vines of the old Black Cluster, a variety one so often sees recommended as a good and free-bearing Grape for out-door culture; yet, so far as my own practice goes, it is not nearly so certain a cropper, nor yet so prolific, as the first-named, which, if it never produced a berry, would yet be invaluable as a hardy-climbing foliage plant. I attribute much of my success to the open condition of the border, which is literally a mass of old foundations; and, for like positions, I know of no more profitable use than the culture of Grapes for wine making. These Vines were planted twelve years ago, and have never been manured but once during the whole time. My garden is only a mile or two from the Trent, so that it can scarcely be called the sunny south. I should be glad to hear how far north the Grapevine will ripen its fruit in this country.

J. C. P.

Melton.

Wiring Garden Walls.—It has so happened that I have had no practical experience with wired garden walls; but from what I have seen of them in different garden establishments which I have visited, I have, like your correspondent of last week (see p. 332), been led to regard the system as a very decided improvement upon the old nail and shred method, which is open to many objections. And I confess to having been somewhat puzzled on reading Mr. Baines's unqualified condemnation of the wiring system. Nor was I much less astonished at his assertion that nails ought to be driven into the bricks, and not into the joints. Surely Mr. Baines's nails must be sharper, or his bricks much softer than those with which I have had to deal, or he would not be able to get one nail in fifty to enter a brick. Even, however, if this were not so, I would certainly hesitate to disfigure the even surface of the bricks, by driving nails into them; joints can be re-pointed if desired, but splintered bricks cannot be so easily replaced by whole ones. My only object, however, in noticing this matter is to endeavour to elicit from some of your readers, who may have had experience with wired walls, if there really exists any reasonable objections to the use of them? If so, it cannot surely be the distance at which the branches are kept from the surface of the walls, which need not be more than the thickness of the wire itself, and that is, of course, infinitesimal.—P. GRIEVE.

—I have not the least doubt that "One Who Practically Knows" (see p. 332) is well acquainted with wire-work, but that he is no fruit grower is evident. When the writer talks of boring holds in the mortar with a gimlet, to admit nails in Peach-training; the next thing I should expect him to tell us is, that he prunes his trees with a chisel. Nearly twenty years ago I had walls as well wired as ever "One Who Practically Knows" could wish to have them, and I can point to numbers of places where the system has been done away with for the reasons I have given, and others which I did not mention.—T. BAINES.

Flavouring Strawberries.—When my Strawberry sets are fully coloured in the Pine-stoves or Melon-houses, I remove them to a late Vinery—an operation which not only vastly improves their flavour; but the display made by them in such houses my employer much enjoys. Walking in a temperate climate, inhaling the delicious fragrance of this fruit, is a treat easier to realise than describe.—R. GILBERT.

A New First-class Pear.—The current number of the *Revue Horticole* contains a coloured plate and a description of a new Pear named *Favorite Morel*, a seedling from Williams's Bon Chrétien, raised by M. Morel, of Vaise-Lyon. The fruit is of good size, and handsome in shape and colour, the flesh is white, fine-grained, melting, juicy, and agreeably acidulous, ripening from the end of September to the middle of October or later. The tree produces abundantly, and does well on the Quince stock. M. Carrière recommends the fruit as being in every respect of first-rate quality.

TREES AND SHRUBS IN AND NEAR LONDON.

It has been said that there is no street in London in or from which you cannot see a tree; a statement not literally true; but there are more trees even in the middle of London than a stranger would guess. The tall Oriental Plane in Wood Street, Cheapside, has a rook's nest in it. A sister tree, and, perhaps, a larger one, spreads its arms over Stationers' Hall Court, and there are two good ones, much haunted by sparrows, in the mysterious region of Doctors' Commons. In one of the courts of Bartholomew's Hospital are some well-grown trees, and others adorn the garden of Mercers' Hall. The Bank of England itself, square stone mausoleum as it looks, has a garden in its heart, gay with flowers and bushes. One of the most unlikely places for greenery is a sunk court in the stony area of Somerset House, yet there three or four Hawthorns manage to live and grow. In Gray's Inn is a shady Elm avenue, trees not the same, but successors of those under which Lord Verulam used to pace and meditate, and haply made there his pretty piece "Of Gardens." The famous essays are dated "from my chamber at Graies Inn, this 30 of Januarie, 1597." "The Creator first planted a garden," he says, "and indeed it is the purest of human pleasures; it is the greatest refreshment to the spirits of man; without which buildings and palaces are but gross handiworks." In many another space and square, and in many an unsuspecting nook in the very thick of the town, as, for example, behind certain houses near the British Museum in Great Russell Street, and behind others in Great Ormond Street (among which latter is a Fig tree of unusual size), and among the crooked lanes south of Westminster Abbey, trees continue under all difficulties to present to those in populous city pent the boon of their varying interest and beauty. The roads, walks, shrubberies, and flower-beds of Kensington Gardens and Hyde Park are kept, on the whole, in pretty good order; in some parts exquisitely, in others not so well as one would naturally expect, considering the metropolitan importance of this two-fold *rus in urbe*, and the large sums of money annually expended on it. The old trees, the pride and glory of the expanse, are, to all appearance, allowed to rot, and fall one by one without any of those attempts to prolong their lives which are successfully made for so many of their leafy brethren in the parks of other countries and of private owners. As a tooth cared for by the dentist, a tree may be saved for ever so long by timely attention. A plate of zinc, or a kind plaster of tar, would often give the dryad a new lease of her mansion. Caked and hardened ground should, in some cases, be stirred—new earth deftly supplied—an artificial shower, at need, drizzled from the far-shooting hydrant or hose. But this and that majestic old tree must not only strive against the acids and soot-flakes of London air, but endure the slow rot of rain sinking into its hollow places, and the racking of the wind upon its weaker joints and branches; and one vegetable King Lear after another breaks, falls, and lies ruined. As a further proof of neglect, you will often find the prostrate trunk or huge dissevered limb lying for many months in the place of its downfall, obstructive, puddle-making, ugly, slovenly, discreditable. The corner of Kensington Gardens, near the fountains at the top of the lake, a very conspicuous part, lay in a dismal condition for several years past, with mud, dust, baldness, and ruined trees. It has lately begun to look a little better, the rubbish having been, at long last, cleared away, and the Grass allowed to grow by the simple expedient of partly fencing it on one side. But other parts of the gardens are in an ugly and neglected state. That huge knotted Elm, surrounded by a bench, near the water, the greatest of its tribe in these woods, still stands firm and apparently sound; but decay may be at work. I cannot gather that any regular inspection of the trees is made. A very pretty and well-tended piece of shady garden, not much known, is that which adjoins on the east the opener grounds at the back of Chelsea Hospital, with a railing between. This eastward garden, with smooth winding walks, lawns, flower-beds, summer-houses, clumps of shrubs, and some handsome taller trees, still bears the name of Ranelagh, and is part of the famous Ranelagh Gardens of the last century, which further extended over the ground where you now see that huge barrack for the household troops. The north part of the present Ranelagh, a wide quadrangular space, sheltered by trees and shrubs, the red walls of the hospital peeping up on the westward, is occupied by the Old Men's Garden, a number of little plots of ground cultivated by the same number of pensioners for their private amusement and benefit. There are ninety-two of these little gardens, each about 18 feet square, only divided one from another by narrow walks, where you see here and there an old soldier in long blue coat and peaked cap creeping about and bending among his flowers and vegetables. Each follows his own fancies in the matter of gardening. One grows Peas or Beans, another Potatoes, a third Onions, a fourth Lettuces, a fifth Scarlet Runners, for staple; but few are so prosaic as to have no flowers, while many others make these their

chief boast. There is nothing that a horticulturist would deign notice. The old-fashioned cottage blooms and pot-herbs, with the fragrance of long-gone springs and summers, are still the sole favourites here—Sweet William, Snapdragon, double Pinks, Lilies, dwarf Rose, Larkspur, Wallflower, Gillyflower, Batchelor's Buttons, Gentian, Musk, Thrift, Lupin, Columbine, London Pride; green Rosemary, Rue, and Southernwood; the lofty Hollyhock, and the lowly Heart-ease. Some of the old gardeners have architectural whims; one man has erected a castle of pebbles, five feet high, on whose topmost tower flies the Union Jack, another a kind of sentry-box encrusted with clam-shells, and two or three have with better taste twisted up little arbours. The few oddities are not enough to disfigure, only serve to accentuate the impression of a variety of individual tastes at work, which gives a peculiar interest to the composite garden, made up of ninety-two pieces; and the general result has sufficient unity of effect, helped by the broad public walk which goes round the four sides of the whole space and binds them together. A little westward from Chelsea Hospital is one of the oldest gardens in London, that of the Apothecaries' Company, made between 1673 and 1686, the latter year being probably the date of the wall, as inscribed thereon at the east gate. The freehold of the ground was given them by Sir Hans Sloane, in 1721. It looks, you peep through the iron gate, just as a "Physic Garden" ought to look, dingy and formal, and as though laid out for growing Senecios and Squills; in fact, its chief crop seems to consist of labels. The few trees, too, are mostly of a sombre and funereal aspect, one black Cedar, some Holm-Oaks, and a couple of specimens of Chinese Arbor Vitæ, which resemble gigantic hearse-plumes. Vegetables, Porcupines, of the Cactus tribe, present their usual uncompromising aspect here and there; and a statue of Sir Hans, bewigged and grimy, stands in the centre. Battersea, the last made of the metropolitan breathing spaces, is a very promising young park indeed with its pretty boating lake and sub-tropical gardens, its lawns for cricket and football, shrubberies, and, above all, its long terrace of the Thames, which forms its northern boundary. The ragged and marshy Battersea Fields, with their Willowy ditches and scraps of Cabbage garden, were raised into this new and noble condition under the care of Mr. Gibson. The only tree of any height in Battersea Park are some Willows and Poplars, the oldest inhabitants of the region. That tall group which decorates the west-end of the really charming island, with its beds of Reeds and water Lilies, is the haunt in autumn of numerous starlings, and any fine evening you may see and hear a flock of the wheeling with multitudinous twitter above the foliage ere they settle for the night. In St. James's Park, too, the Willows and Poplars are the chief ornament, especially those on the island facing the new India Office. The old Elms that remain are much in want of looking after. The best trees of the Green Park are all in that dell facing Engine Street, Piccadilly, some large Horse Chestnuts the most notable; but the ground beneath, which might be made remarkably pleasant, is needlessly abandoned to be trampled into dust and mud. Hyde Park has not many great trees. Its chief charm is the wide airy upland (permit the word) between the Marble Arch and the Serpentine, but there are trees in Hyde Park. The south side of the Serpentine is well wooded, and on the north side stand some sturdy Elms, thick of bole, with pleasant seats from which to look at the gliding toy ships, the pleasure boats, and the water-fowl that whiten with their dropt feathers that new-created Island. The rural part of Hyde Park, is round the Deputy Ranger's lodge, a very table grange, with its home trees, garden and paddock. And (London being packed full of contrasts) near this peaceful scene, but just a little farther east is "The Reformers' Tree," a good-sized Elm some 10 feet in girth, the outside one of a row of eleven, two being stumps. Taking the path from this noble tree—the future goal perhaps of admiring pilgrims—towards the Serpentine Bridge, we pass a Birch grove, and a few sturdy Oaks. At the north-east corner of the bridge are four noticeable trees with light-coloured stems (Canadian or Cotton Poplars), their twigs in March thickly hung with long catkins. And so we come again to Kensington Gardens, the place in all London for the lover of trees, when he has no time for the outlying shades of Richmond or Greenwich. Just inside the gate, behind the powder magazine, look at this group of Pollard Chestnuts, about twelve in number, the oldest trees, probably in the gardens; this one is the biggest—broad, squat, grotesque. Another, you see, though still full of life and budding twigs, is stripped of its bark, and the denuded wood is full of cracks, which call for some kindly surgery. "Be sure," says Evelyn ("Sylva," I. III. ch. ii), "to emplaster great wounds to keep out the wet." On the other side of the pathway stands an old Pollard Oak, a worn veteran in his veteran side, which the rain falls into, and idle fingers enlarge. See those freshly broken bits of wood lying on the Grass. So enter on the slope east of the Serpentine, a fine country-like space

grass, bordered with trees, which form a grove on the side next the water. Here are large Elms (two especially grand), Horse Chestnuts, and a few tolerable Beeches. Passing the ugly fountain-plateau, which needs entire remodelling, and the majestic Elm by the water-side, already mentioned, we see about a dozen stumps of various heights of wind-wrecked Elms, still living and sprouting, but the broken boles not protected in any way from the weather. Keeping near the Bayswater boundary, on our westward way, we note near Lancaster Gate some great Horse Chestnuts (which want looking after), four or five Beeches, and then a picturesque grove of Scotch firs, their tall bare stems and flat heads looking like those of so many Stone Pines. They are about twenty-one in number, but six are dead, and six more are in a bad way. The bark is coming off in patches, and from the holes in the wood it is evident that some insect is at work. Can anything be done to save the sound trees? The dead ones might be polled and made props for Ivy to climb upon. The adjacent Linden grove looks wery spindly, and in need of thinning. Now we cross the great Elm Avenue from Kensington to Bayswater, unrivalled of its kind in all the parks, even including Richmond and Greenwich, and pass into a singular and delightful region in the westward part of the gardens, behind Wren's conservatory, with a Plutonian grove of Yews, and three tall Cedars lifting their blacker heads high above theirs. Some good-sized Hollies fringe the outer limit, and that bowery Holm-Oak shelters a seat, seldom occupied; a pleasant place in March, the sun shining over the low hedge bordering our westward walk, nest-building rooks hovering and cawing round the tall Elm-tops, and a blackbird haranguing the woods and sky, as though London were fifty miles away.—*Fraser's Magazine*.

WORK FOR THE WEEK.

Flower-garden and Shrubbery.

EVERGREEN trees and shrubs may still be transplanted, mulching the roots with litter or leaves, over which an inch or so of soil should be placed. From Conifers all contending leaders should be removed, leaving only the most promising; where there is a deficiency of vigour in the leader, it should be encouraged by judiciously removing the points of the side branches, or, if necessary, thinning them. Hardy Ferns wintered in pots may now be planted in Ferneries out of doors, or in other shady spots. Annuals, such as Mignonette, Campanula, and Candytuft, should be sown out of doors, where they are to bloom. American Aloes may be planted or plunged outside in beds, or placed on rock-work, or in vases where they are to remain during summer; in case of frost, a mat may be thrown over them. Plantings of the hardier succulents around flower-beds and borders may be made. Hollyhocks, the better kinds of Foxglove, Sweet Williams, and Rockets, may be planted out where they are to remain. Radioli should be planted, Box edgings pruned, and Ivy clipped. The ivy should be cut close in to the wall, even though it should be rendered leafless; in a short time it will be covered with the most beautiful bright green young foliage imaginable. Broad Grass walks may now be trimmed and swept, and lawns regularly mown and rolled.

Stoves and Greenhouses.

Plants of young and tender growth should be protected from bright sunshine, especially when the leaves are damp. Put a few rat stakes amongst the leaves of the earliest started Caladiums, so as to keep them from being broken. Place the young stock of Palms, Cycads, Dracaenas, Ixoras, Crotons, Pavettas, &c., in a warm moist temperature; and if a brisk bottom-heat can be given, so much the better for them, as, in that case, the plants start freely into growth, and develop their foliage in greater perfection. Re-pot the stock of Cactaceae. Plants belonging to the macrorrhiza section of that genus are partial to a good substantial loamy compost; whereas, those belonging to the metallica delight in an open turfy soil. They like plenty of water, both at the root and in the atmosphere; indeed, A. metallica and Marantas would thrive set on inverted pots in an aquarium—i.e., if the bases of the pots were just above the water. Canophyllums, Sphaerogynes, and Medinillas also enjoy a similar position, and the large and magnificent foliage they produce under such circumstances amply repays any attention they may receive in that way. Put some Tradescantias of the discolor section in 4 and 6 inch pots, and keep them for a time in a brisk moist temperature, when they will make excellent flowering plants. Start Clerodendrons of the fallax, fragrans, and Kämpferi section, and give climbing ones plenty of string to support their growing shoots. As soon as Crinums have done flowering, re-pot them in good substantial loam mixed with well-decomposed manure. They may be bloomed in the same pot for two or three years in succession, if the specimens are large, in which case manure-water should be given them. Centradenias

make useful winter plants, if propagated from cuttings now and well attended to during the summer. Free Brexias from scale and Ixoras from mealy bug. Allamandas, amongst the best of which are A. nobilis, grandiflora, Hendersonii, cathartica, Schottii, and Aublettii, should now be kept in active growth. Marcgravia dubia is a useful plant, which will cover a stone or brick wall, grow on the wooden rafters on the north side of a stove, or make a nice covering for the stumps of Tree-Ferns; indeed, the Marcgravia, dwarf-climbing Ficuses, Æschynanthuses, and similar plants, thrive admirably in such situations. Cut back plants of Scutellaria Mocciniana, and pot and start them into growth. Cissus discolor (a plant which well deserves every encouragement) enjoys heat and moisture when growing, and is rather partial to a slightly shaded nook; cut back old plants close to the main trunks or shoots so as to induce them to start afresh; the divisions of the cut-away shoots will then strike freely, and form nice little plants for either suspended baskets or for pot trellises. Torenia asiatica, various sorts of Æschynanthus, Coccocypselum discolor, Panicum variegatum, Hoyas, Selaginellas, some Ferns, and Dracaenas for centre-pieces, are also suitable for basket-work; but, if a little extra shade can be afforded, many other plants, such as the beautifully-leaved Philodendron Lindenii, Pothos argyrea, different kinds of Cissus and Pitcher plants, may be effectively employed for the same purpose. In conservatories, Camellias done flowering, and other evergreens not in blossom, should receive copious syringings on bright mornings; air should be freely admitted, and a slight shading afforded during bright sunshine. Tying, thinning, staking, and keeping the plants free from insects, should receive daily attention. Plants that have been forced may now be put into pits or frames, and gradually exposed to the air.

Pits and Frames.

Continue to propagate bedding plants, and such as are rooted should be potted or pricked into boxes; those a little established should be gradually inured to the air, and strong well-hardened plants fully exposed, and shut up at night. Pyrethrums, variegated Grasses, Sedums, &c., should be placed outside on wall-sheltered borders, where mats can be thrown over them if necessary. Stocks, Asters, and Marigolds may now be sown on slight hot-beds; and, as soon as up, they should be gradually inured to the air. Those up and fit to handle are pricked off into boxes and pans, and kept near the glass. Auriculas require plenty of water at the root; but great care should be taken to prevent water or drip from coming in contact with their flowers and foliage. Carnations should now be shifted into their flowering pots, and those for outdoor decoration turned into beds or borders. Heartsease may be sown, and established plants planted out. Bulbs done blooming should be placed in frames, where they can be kept rather dry so as to induce them to ripen.

Market Gardens.

The genial weather of the past fortnight has been instrumental in forwarding all sorts of vegetables. Winter spinach is now pushing up strong fleshy leaves, therefore have the beds cleaned and hoed. Hoe and clean Parsley beds after the leaves have been picked for market, and, if not already done, sow some seeds for autumn and winter bearing; March, however, is the best month for this operation. During the last three weeks there has been plenty of Seakale obtained from the open fields, in which it is cut as soon as the tops are discerned making their way through the earthed-up soil. Finish the earthing-up of Asparagus ridges. Parsnips are now beginning to appear; therefore, where Lettuces are planted between the lines, they should have the earth about them loosened with a short hoe, and the alleys between, i.e., where the Parsnips were sown, raked smoothly, but not deeply, with a foot-wide iron-toothed rake, so as to break the surface and to facilitate the egress of the seedlings through the soil. Earth up Beans and draw the rake over the soil where they have not yet germinated. Beans are generally planted in rows 2½ feet apart, with a line of Cabbages between them, the latter being removed before the former require the space. Radishes will now grow quite freely without coverings of litter—i.e., if the weather keeps fine and birds are kept off them. Therefore, remove such protection, which should be placed in the bottom of the manure heap to soak and rot. Still, however, keep litter on Rhubarb, for under it the leafstalks always come cleaner and crisper than when grown uncovered. Plum trees are in full flower, Pear trees are extremely promising, as are also Cherries; indeed, the fruit harvest, if uninjured by frosts and dry easterly winds, bids fair to be a good one. Cucumbers should now be planted out in frames, and well covered at night with litter. Keep the frames close for some time after they have been planted out. Those who grow Melons should now plant them in the frames in which they are intended to be grown.

ROYAL BOTANIC SOCIETY.

APRIL 22.

THE most notable plants exhibited on this occasion were Azaleas, Roses, Orchids, and Dielytras, together with Clematis, spring-blooming decorative plants, and florist's flowers, all of which were well represented, and the gardens themselves never looked fresher, cleaner, or better, than they do at the present time.

Stove and Greenhouse Plants.—Of these, Mr. Ward, of Leyton, staged a dozen nice little specimens, among which were *Erica profusa*, well-flowered, two plants of *Lycaste Skinneri*, *Cypripedium villosum*, *Odontoglossum Pescatorei*, three nicely bloomed Azaleas, and other plants. Mr. Wheeler, Regent's Park, also had a nice group, including *Franciscea calycina*, an old and valuable exhibition plant, Azaleas, *Erica Cavendishi*, and *Lycaste Skinneri*. *Dielytras* were very very fine, Messrs. J. Veitch & Sons being first with plants a yard through, fresh in aspect and profusely flowered. Mr. Wheeler had smaller plants trained in rather too stiffly, owing to which they lost much of their natural gracefulness; while Mr. Reeves had still smaller plants, also impaired in appearance by being trained in too formal a manner. In the class for six stove plants, Mr. Ward staged a large spathed form of *Anthurium Scherzerianum*, *Rhynchospermum jasminoides*, nicely bloomed, and a well flowered plant of *Franciscea calycina*. Mr. Wheeler, also, had a neat group of smaller plants. Messrs. Lane & Sons contributed a pretty group of twelve *Rhododendrons*, the varieties, and, in some cases, the plants, being the same as those shown last week at South Kensington. Messrs. Jackman, of Woking, again staged a beautiful group of *Clematis*, well-grown and profusely bloomed; Cape Heaths in good condition came from Mr. Ward, who had fine plants of *E. depressa multiflora*, *elegans*, *mirabilis*, *aristata major*, *tricolor Eppsii*, and *Cavendishii*. Mr. Wheeler had a smaller group rather past their best. Messrs. Low & Co., of Clapton, staged six plants of *E. Lowii*, a fine variety of the *aristata* group, having large inflated crimson flowers, slightly glutinous; it appears to be robust in habit, and will prove a fine exhibition variety of this useful genus.

Azaleas.—Messrs. Lane of Berkhamstead had some examples of what are called half-specimens, remarkably well bloomed, including *Flag of Truce*, a fine semi-double white; and *Comet*, a brilliant scarlet, suffused with metallic purple. Mr. Wheeler's collection consisted of smaller plants, the best of which were *Model*, a fine flat flower, of a delicate rosy-lilac; and *Stella*, one of the best, resembling *Comet*, but not quite so brilliant. Mr. James's group consisted of still smaller plants, but, so far as cultivation went, they were nearly perfect, the plants being trained in a natural manner, and well bloomed. Of these the best were *Criterion*, a fine rosy-lilac variety, edged with white, the top petals spotted with deep rosy-crimson; *Duc de Nassau*, a rich lilac purple, with a very large semi-double flower, each segment being beautifully crisped round its margin. In the Amateurs' Class, Mr. Marcham also furnished six large plants very well flowered.

Roses in Pots.—Of these some fine examples were furnished by Messrs. Veitch & Sons, whose plants were perfect pictures of health and vigour. Among them were *Paul Verdier*, a well-known old rosy-crimson variety; *Centifolia rosea*, another fine well-known Rose, and one of the best for pot culture; *Charles Lawson*, a fine deep rosy-tinted variety; and *John Hopper*, a deep rosy-purple, with silvery-lilac backs to its beautifully-incurved petals. The best Tea-scented varieties in this group were *President*, a profuse-blooming variety, with well-formed salmon-tinted flowers, and *Madame Willermoz*, a good white-tinted kind with delicate flesh. Mr. W. Paul, of Waltham Cross, staged a larger collection of smaller well-bloomed plants, among which we noted the new Tea-scented variety called *Madame François Janin*, a beautiful buff kind, with fine bright wax-like foliage; *Catherine Mermet*, another excellent variety of a delicate flesh colour of fine form, but, in this instance, a little past its best; *Perfection de Montplaisir*, a fine sulphur-tinted flower, belonging to the same group. Among the hybrid perpetuals we noticed *Princess Beatrice*, a very round and full-flowered variety of a delicate rosy-lilac colour; *St. George*, a new variety with large smooth petals, rather rough at the edges, and of a deep velvety-crimson; *Etienne Levet*, a fine deep rosy flower, with large smooth petals; this was introduced a few years ago, and is a good addition to Roses suitable for pot culture. Mr. Paul also showed two other new seedlings, *Perle des Blanches*, a paper-white variety, the flowers being borne in clusters of four to seven at the end of each branch, it will be useful for pot culture or for cutting; the other, *Mlle. Marie Arnaud*, is a sulphur-coloured Tea-scented kind, and, as shown on this occasion, promises to be useful for furnishing cut flowers, the buds being nearly perfect, although not so compact as those of *Madame François Janin*, to which we have already alluded. Cut Roses were shown in fine condition by Mr. Walker, nurseryman, of Thame, near Oxford, two boxes of *Maréchal Niel* were perfect and very richly coloured. In another stand were blooms of *Adam*, a fine fresh coloured Tea, *Duchess de Caylus*, *Charles Lefebvre*, *Souvenir de la Malmaison*, *Gloire de Dijon*, and other well-known favourites.

Florists' Flowers.—Among these, *Cinerarias* were shown in good condition by Mr. Marcham, who had bushy plants of *Her Majesty*, a fine purple flower with a white centre; *John Mitchell*, a deep purple self; and *Duc de Magenta*, a deep crimson self. Mr. Waters, gardener to A. Mon-gredien, Esq., Forest Hill, contributed some pretty plants, including *Purple Prince*, a deep purple-rayed variety with a white eye; and *Clara Oswald*, a fine blue flower. Blue flowering plants, always scarce during the spring months, are likely to be substantially reinforced by means of blue-flowered *Cinerarias*, now so extremely popular in Covent Garden and elsewhere. Mr. James, Isleworth, also showed a collection of dwarf, well grown, and profusely-flowered plants, and also

staged a nice collection of fancy and Alpine Auriculas. Some fine blooms of Pansies, in good condition, were furnished by Mr. Hooper, nurseryman, Bath; and the same exhibitor had a large box of a black and white bedding Pansy, named Mrs. Felton.

Miscellaneous Plants.—Of these Messrs. Veitch had an effective group, including most of the novelties alluded to by us last week. The collection included half-a-dozen choice Orchids—viz., *Oncidium fuscum*, *O. concolor*, *Epidendrum bicornutum* (with two spikes), *Masdevallia Lindenii*, *Cattleya gigas*, and *C. Mendelii*. *Dracæna Hendersonii* is a finely-marbled variety, and colours well in a young state. The group included some of the elegant cut-leaved bronze-tinted Maples, and a fine basket of the hardy spring-blooming *Azalea mollis*. Two pans of *Drosera* were very interesting; and the same firm sent a plant of *Agave Leopoldii*, a stout form something in the way of a dwarf *A. Verschaffeltii*, but with stout dark brown wavy spines at the apices of its fleshy leaves. *Amaryllis*—Half-a-dozen fine plants were staged by Mr. Harborough, gardener to C. Kaiser, Esq.; and a new garden hybrid, of a bright crimson colour, named *A. Mooreana*, was staged by Mr. B. S. Williams, of Holloway. Mr. B. S. Williams staged a very effective collection, the most notable plants being *Dendrobium nobile*, alluded to in our last week's issue; *Imantophyllum miniatum*, with fine trusses of orange-scarlet flowers; *Dendrobium infundibulum*, *Aërides Fieldingii*, and *Odontoglossum Pescatorei*; besides numerous choice Palms, Ferns, Bromeliads, and greenhouse plants. The same exhibitor also staged new plants, including *Aphelandra fascinator*, with dark silvery-veined foliage (this has recently been figured in the new *L'illustration Horticole*); *Ceterach aureum*, *Sempervivum triste*, *Echeveria pachyphytoides*, *Carludovica plicata*, and others. Mr. Wheeler had a group of ordinary decorative plants, including a good specimen of *Eriostemon intermedium*, *Asplenium (Veitchii) Belangeri*, *Adiantum trapeziforme*; besides Orchids, Ferns, Palms, and flowering shrubs. Mr. W. Paul had a collection of *Clematis* in pots, and also a group of gold, silver, and bronze Zonal Pelargoniums in good condition; but these plants are evidently fast going out of popular favour. Mr. Wheeler had a miscellaneous group of hardy herbaceous plants; and Mr. Needle sent a beautiful and interesting collection of terrestrial orchids from Twickenham. Auriculas—Of these, some nicely grown examples were staged. In the class for six show varieties Mr. J. Douglas, of Loxford Hall, Ilford, was first with fine specimens, amongst which we noted the following: Colonel Champneys (Turner), a fine grey edged variety of a rich purple; Meteor Flag, a rich purple self; Formosa, blue self; Conqueror (Popplewell), a fine white edged variety, good truss; Competitor (Turner), a fine dark grey edged variety. Second, Mr. James, Isleworth, with smaller plants. Third, the Rev. H. H. Dombrain. In the class for one green-edged variety, Rev. H. H. Dombrain was first, with Lancashire Hero. Second, Mr. James, with Lovely Ann. Third, Mr. Douglas, with Appollo. Grey edge: First, Mr. J. Douglas, with a fine truss of Robert Trail (Lightbody). Second, Rev. H. H. Dombrain, with Rob Headly (Lightbody). Third, Mr. James, of Isleworth, with Turner's Competitor. In the class for self, Mr. J. Douglas was first with Turner's Master Hole, a fine black. Second, Mr. James, with Charles Perry, a rich bluish-purple. Third, Rev. H. H. Dombrain, with Spalding's Metropolitan, a fine purple, with coarsely serrate foliage. Rev. H. Dombrain was first in the white edged class with Taylor's Glory. Second, Mr. James, with Highland Queen.

Botanical Certificates were awarded to the following:—

- Ficus Parcelii* (Veitch). Alluded to last week.
 - Dracæna Hendersonii* (Veitch). A free-growing variety, beautifully marbled with red and creamy white, quite distinct and very attractive.
 - Croton ovalifolius* (Veitch). A short blunt leaved form, coloured something like *C. variegatum*, but distinct from any other species, and well worth growing for variety.
 - Abutilon Sellowianum marmoratum* (Veitch). A large leaved golden blotched variety, well worth culture as a half-hardy foliage plant of vigorous habit.
 - Agave Leopoldii* (Veitch). A fine form, alluded to above.
 - Cattleya gigas* (Veitch). A large-flowered form; one of the most attractive plants in the genus.
 - Drosera capensis* (Veitch). A spatulate-leaved species. Interesting as a botanical curiosity.
 - Acer vitifolium* (Veitch). A bright green-leaved species of a novel and interesting group.
 - Acer flavescens* (Veitch). Beautiful yellow foliage most delicately netted with green. One of the prettiest of the whole group.
 - Hypolepis Bergiana* (Rollisson). A beautiful finely-cut species, with bright green hairy fronds 1 to 2 feet long. It does not, at present, show the creeping habit of its congeners.
 - Gymnogramma triangularis* (Williams). A delicate little Fern, not unlike *Cheilanthes* in habit, having triangular bright green fronds slightly powdered with gold beneath.
 - Ceterach aureum* (Williams). Alluded to last week.
 - Betula alba purpurea* (W. Paul). A purple-leaved form of the common Birch, likely to be a useful addition to hardy-ornamental trees.
- Floral Certificates** were given to the following:—
- Azalea Duke of Edinburgh* (Parsons). A very large-flowered variety, the segments being flat and of good substance; colour, deep rosy-scarlet.
 - Amaryllis Mooreana* (Williams). A very rich crimson-flowered variety.
 - Clematis Marikata Oké* (Jackman). A delicate lilac form, with fine wax-like foliage, the petals very broad.
 - Clematis Duchess of Edinburgh* (Jackman). A fine semi-double white variety, having remarkably fresh and handsome bright-green foliage.
 - Clematis Sir Garnet Wolseley* (Jackman). A fine bluish-purple variety, and a decided acquisition.
 - H. P. Rose Perle des Blanches* (Paul). A beautiful flower of papery or snowy whiteness, blooming in clusters like a Noisette.
 - H. P. Rose St. George* (Paul). A deep and vivid crimson flower of good form.
 - Tea Rose Madame Marie Arnaud* (Paul). A delicate sulphur fine in bud.
 - Tea Rose Madame Jules Margottin* (Paul). A fine robust grower, with fine wax-like foliage and delicate salmon-tinted flowers.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE INFLICTIONS OF FASHION.

By T. BAINES, Southgate.

THE higher the point of civilisation at which a country arrives the more its inhabitants become the votaries of fashion; and at we, in this country, enjoy no immunity from this infliction, is everywhere evident. If this did not extend beyond an indulgence in the luxuries of everyday life it would be a matter of less consequence; but, when the infliction spreads to matters of such importance as horticulture and arboriculture, behoves those who take an interest in these pursuits to look at the matter fully in the face. It may be said that gardening, as it exists at the present day, is a luxury, and that, consequently, it must be governed by such fanciful laws as rule matters of a kindred character; this, it must be admitted, is correct, so far as it relates to the purely decorative element, but here it does not stop. The introduction of a new genus of plants, or the substitution of an old, and, in many cases, an undeservedly neglected one, appears to be the signal for a universal mania in favour of the favourite of the hour to the comparative neglect of other things. When a useful plant makes its appearance, such as a Tricolor Geranium, Mrs. Pollock, for instance, why should we for years run mad after Tricolors by the hundred, that have barely an infinitesimal difference from each other? In the matter of new Roses there might be some excuse; for any improvement relating to the queen of flowers is sure to be hailed with delight. But may I ask how often in these are our expectations realised in proportion to the disappointments we experience? The time has come, I think, when there is little necessity for deriving our supplies of new Roses from the Continent. The Roses of recent years, raised by English growers, are sufficient evidence of this, and in the case of these we at least have a better opportunity of ascertaining something of their general character, previous to purchasing, than we have in the case of those of foreign origin. At present it would appear that we are on the verge of a Lily fever. This, if not carried too far, may be looked upon as simply the *amende honorable* for the neglect to which this flower has been allowed to fall. Thus far have we been dealing with what may be termed the elegancies of horticulture. But now come matters connected with the more essential and indispensable branch of gardening. First, let us take the ever-recurring rage for new Peas, nine-tenths of which are deficient in general properties compared with others they are intended to supplant. Then, as to new Potatoes, they make their appearance by the hundred. In this, too, we are aided by growers across the Atlantic, whose timely assistance we should receive with gratitude were it not that, when their varieties are proved, they are found inferior to our own, to say nothing of the exorbitant prices asked for them. Let us now advert to new fruits, more especially Grapes. How much disappointment has there been experienced by those who have supplanted old and well-tried varieties largely with new ones, which, after trial, have, in many instances, either been rooted out altogether or have had their heads cut off, and been made to do duty as stocks. These are a few of the positive inflictions which fashion imposes upon us in matters horticultural. Those of a negative character are also equally baneful. What have we to compensate us for the neglect into which numbers of old and well-tried friends amongst herbaceous plants have been allowed to fall? Nothing, except blazing stripes and circles of red, yellow, and blue, the glare of which is, fortunately, short-lived, for their repetition becomes a positive infliction on the eye. Let us not be misunderstood; no one would discountenance healthy progress in anything appertaining to horticulture, for it, as in other matters, it is human to require novelty and change. But the evil is, that whatever becomes fashionable, whether in any particular family of plants, or in the manner in which we employ them, we for a time lose sight of others of greater importance. Again, if we look to arboriculture,

we find that fashion has inflicted something more serious than a passing disappointment. Both in the vicinity of the suburban villa and in that of the more extensive country mansion, it is desirable to get as much variety as possible; this no one will attempt to deny; but have our planting operations for the last thirty years been judicious? Have they not been governed, to too great an extent, by a rage for novelties in the shape of Coniferous plants, numbers of which are unsuited to the situations in which they have been planted, and are incapable of withstanding our occasionally recurring severe winters, leaving blanks that take years to fill up. Think of the numbers of grand deciduous trees and flowering shrubs that, comparatively, have been cast into the shade by these new comers. In this case, dear-bought experience would appear not to have had much salutary effect—that of the winter of 1860-61—when, in many a fine place, the destruction was such as one might have thought would have ensured caution in planting things that were evidently unable to withstand our severest winters. Let us go still further back and see what has been done as regards the planting of timber trees throughout the kingdom, for, say, these last eighty years. What gain to us have been the trees that we have substituted for the Oak, Ash, and Elm planted by our ancestors? Great things were expected from the Larch, but, unfortunately, it turns out to be worthless in many situations, so subject to decay is it at the core. The destruction of hedge-row trees, which high-farming entails, has so far lessened the supply of late years, and the great increase in the price of iron has caused so much greater demand for our old English Oak, as well as for Ash and Elm, that it is evident that none of the timber trees recently introduced are likely to supplant them in a national point of view.

MIXED PLANTING VERSUS GROUPED TREES.

THE editor's description of a garden at Verona in THE GARDEN of the 25th April, and of the Cypress grove therein, revives an oft-felt regret that the system of mixed planting has attained to such a degree that the home scenery of this country, beautiful as it is, is somewhat marred by a monotony which, by a more artistic treatment, might have been avoided. The art of forestry has always suffered under the sorrowful thought that the planter is preparing beauty which he will never be able to share with posterity. We plant our parks and gardens with a view to effects that we may never see, and it is fortunate if our successors understand and are willing to carry out our schemes. The following motives in managing ornamental woods may be worth consideration by those who are engaged in planting, or, as not unfrequently occurs, who succeed to long neglected and extensive woodlands. By mixed planting, we ascertain what trees thrive best in varying soils and exposures, and having practically acquired this knowledge it should be acted on intelligently and decisively. Given 100 acres of park with undulating varying soil, planted with mixed trees for shelter and ornament, probably the highest degree of beauty and character would ultimately be obtained in the following way. When the first thinning is undertaken, the designer should go all over the wood. He will find unmistakeable differences in the uses which the trees have made of the time since they were planted. Where the soil is deep and heavy, the Oaks will look unusually clean and healthy. He will not err if he sacrifices everything else to make this a grove of Oaks. Here, perhaps, is a bleak hill-side, exposed to prevailing winds, the soil light and shallow. In such a place, the most promising plants are probably Silver Fir, *Pinus Pinaster*, or *P. austriaca*. On the crown of the hill, the Scotch Firs will be masters of the situation. Let him look a hundred years ahead, and see here materials for a striking picture—gloomy depths of the heavy Pinasters; further on the stately Silvers, in rank after rank; and, on the height, a crest of the more lightsome Scotch Firs. Here, he will be encouraged to establish a dell of Beech trees; there, a company of Ashes. Then, some trees tend themselves to the formality of avenues; indeed, Lime trees, Yew, Beech, and Araucarias seem to attain their highest character when so employed. Thoughtful design will bring a higher reward than indiscriminate planting of any kind.

SALMONICEPS.

NOTES OF THE WEEK.

— WE are informed by Mr. Wills that in the decorations at the Mansion House last Wednesday upwards of two tons of Ivy were used in draping the pictures, mirrors, and walls, and that amongst the cut flowers were upwards of 2,000 blooms of Maréchal Niel Rose, and large quantities of Stephanotis, Gardenias, and other sweet-scented flowers, while among the plants employed were Palms, Pandanads, Marantas, Aralias, and Orchids.

— DURING the past week we have noticed one or two Horse Chestnuts in full bloom, more especially one opposite the Knights-bridge Barracks, in Hyde Park. The Horse Chestnut is one of the most distinct and ornamental of all round-headed trees, both in foliage and flower. As a town tree, it has one fault; its leaves die off very early. It is a pity one does not oftener see the rosy-flowered Pavias grouped with the Horse Chestnuts, for the sake of contrast.

— THE show of choice Orchids which has been so attractive to visitors at the Royal Exotic Nursery, Chelsea, for several months, is just now, if possible, more effective than ever. The cool Orchids are now well represented by dozens of the beautiful, but variable, *Odontoglossum Alexandræ*, one variety of which is by far the most richly-coloured of any we have yet seen. These are set off by the rich purple or puce-tinted *Masdevallia Harryana* and *M. Lindenii*, *Cattleya Mossiæ*, *C. Mendelii*, *Vandas*, and *Dendrobies*, completing one of the best displays of choice Orchids we have yet seen.

— A SCHEME is on foot for the establishment in Liverpool of a Crystal Palace, with winter gardens attached. It will be modelled on the plan of the Crystal Palace at Sydenham, and most of the features which have made that resort so famous will be here reproduced. It is intended to construct a large aquarium, and to have Zoological Gardens and spaces for out-door recreation attached to the palace. Several of the leading public men and merchants of the town have signified their approval of the scheme, and a proposal will, in a short time, be laid before the corporation for establishing the new institution within, or in connection with, one of the public parks.

— THE gardens at Alton Towers, which, through the liberality of Lord Shrewsbury, are thrown open to the public between May and July, are generally considerably damaged by the thousands who frequent them. On this account his lordship contemplated closing them this year; but has recently been induced to alter that determination. No excursion parties will, however, be admitted after the 31st July, though visitors by ordinary trains on Wednesdays and Fridays in each week, may inspect the gardens and grounds after that date, as heretofore. The restriction just alluded to is imposed on account of excursionists trampling on the edges and margins of the terraces, and scattering paper and bottles about the grounds, besides otherwise annoying Lord Shrewsbury and his family.

— WE must protest against the colour of the painting which is now disfiguring the fine stretch of iron railing which divides the Temple Gardens from the Thames Embankment. At first sight we thought it simply a preparatory coating of red lead laid on to protect the metal, but, on a nearer view, we found that several of the workmen were engaged in the final operation of gilding the rosettes. The selection of this colour (to whomsoever it is due) is particularly unfortunate, marring, as it does, all the fine effect of the greenery of the trees and shrubs now bursting into leaf in association with it. It also stands out in prominent contrast with the whiteness of the stonework which supports the railing. Passers-by, of all classes, pause to look at it, and are unanimous in their condemnation of the unhappy effect produced by it. We should have thought that some neutral tint would not only have harmonised better with the gardens of the Temple and their surroundings, but would have also formed a much better relief to the very expensive gilding, which, on its present ground-work, is to a very great extent thrown away.

— ONE of the permanent features most valued in connection with the Crystal Palace is its gardens. Since Sir Joseph Paxton first designed them, more than twenty years ago, the copses and trees have had time to become umbrageous; and at this season, when the spring flowering trees and shrubs are in perfection, there are few sights to be met with of such exceptional beauty as can be gained from the rockery, from all points of which Sir Joseph arranged real pictures in the way of landscape scenery. Near the rockery, now covered with Gorse, Broom, and Ferns, are numberless blossom-bearing trees and shrubs, among which the snowy *Mespilus*, flowering earlier than some others, double white Cherries, Lilacs, Laburnum, pink and white Thorns, scarlet and white Chestnuts, and Magnolias are grouped in profusion with trees of graceful foliage. On the rising ground, near the north end of the great fountain, is an interesting example of Weeping Beech. The shrubs around this

have lately been cleared, so that the clustering proportions of the tree may be better viewed. The Rosery, on the corresponding mound near the railway-station, has been re-arranged; as have all the Rhododendrons in the terrace beds and in other parts, and the improvement of other portions of the grounds has not been neglected.

— THE winter garden scheme at Bournemouth has met with the hearty concurrence of the authorities, and its erection is to be commenced forthwith.

— WE learn that a company is in process of formation for erecting a Winter Garden at Brighton. The land selected for the site was lately in the market for £30,000; but when the company offered to purchase it, the price suddenly rose to £45,000.

— A MARKET GARDENER living at Barking has been fined £1 and costs for offering for sale in London vegetables in a condition unfit for food. Doubts were also expressed as to whether he should not have been sent to prison without a fine.

— WE observe that the Royal Irish Academy has sanctioned among other grants from the fund at its disposal for aiding scientific researches, £39 17s. 11d. to Dr. Moore of Glasnevin, for investigating and cataloguing the Irish Hepaticæ.

— MR. MICHOLS's fine collection of stove and greenhouse plants was sold by auction on Wednesday and Thursday last, and realised large prices. The first day's sale fetched about £1,100; one of the highest priced plants sold on that day being a noble *Anthurium Scherzerianum*, which fetched some £60. The result of the second day's sale will be given next week.

— THE French, Belgian, and Italian Railway Companies have made a reduction of 50 per cent. on the carriage of all articles sent to the approaching International Exhibition at Florence, which will be opened on the 11th of next month. The same reduction has been made by the Italian companies in the fares of visitors to the exhibition.

— A PARIS journal states that the annual cost of securing shade trees, flowers, and rare plants for the parks and public walks is as follows:—"Bois de Bologne (keeping), 387,000 francs; Bois de Vincennes, 270,340 francs; squares, 545,220 francs; cost of plants, flowers, &c., 40,000 francs; expenses of the houses, 11,000 francs; total, 1,253,560 francs (£501,422)."

— THE Pharmaceutical Society have offered a silver medal for the best herbarium collected in any part of the United Kingdom between the first day of May 1874, and the first day of June 1875. The collections to consist of British flowering plants and Ferns obtained in a wild state, and arranged according to the natural system, the collections to be accompanied by lists, arranged according to the same system, with the species numbered. No candidate will be allowed to compete, unless he be an associate, registered apprentice, or student of the society, or if his age exceed twenty-one years.

— A FINE plant of *Angræcum sesquipedale* has recently bloomed under Mr. Dunn's care at Dalkeith. The plant is about 2 feet high, and had five spikes bearing twenty-two very fine blooms with tails from 10 to 15 inches in length, and lasted six weeks in perfection. In the same collection there was in bloom a very fine plant of the Dalkeith variety of *Vanda tricolor*. It bore fifteen spikes having from nine to twelve flowers on each. There was also a plant of *Vanda suavis*—Veitch's variety—with sixteen blooms on one spike, which must be regarded as a very fine example of this fine Orchid. There were other two spikes on some plants of this variety with fifteen blossoms on each. *Vandas* may be regarded as among the very *élite* of Orchidaceous plants, and when not grown under too much shade, and with a liberal amount of air, they are seldom out of bloom.

— WITH reference to the subject of proxy voting at South Kensington, we have received the following from Mr. W. S. Cooper Hillmorton Paddox, Rugby. Dr. Denny stated, he says, that, "country friends made so much about the Society or thought so much about it, they could take the rail and come up to South Kensington to record their vote." Certainly, railway authorities will, doubtless, be good enough to issue us tickets, but naturally they will expect payment in return. May I, therefore, ask if Dr. Denny and the town-anti-country interest are prepared to pay the expenses of rustics? I know not. They would, I think, rather keep us away and quietly pocket our subscriptions. Mr. Bateman hit the right nail on the head when he said "Fellows in the country were those who really cultivated horticulture." Formerly a circular was issued with the names of plants for distribution from the society; now, forsooth, we country members are invited to Chiswick to select for ourselves! More rail. Again there is to be no provincial show this year. Altogether, those who have opposed proxy voting may yet repent of their obstructive conduct.

THE INDOOR GARDEN.

CHAMÆROPS HUMILIS.

THIS is the only species of the Palm family indigenous to Europe, where it is found growing wild as far north as the latitude of Nice. It is common in Sicily and North Africa, especially in Algeria, where it is so abundant as, in some districts, to interfere seriously with ordinary cultivation, as it speedily fills the soil with a dense network of fibrous roots, which send up suckers and prove to the cultivators of that country a greater pest than the Couch Grass of our fields. The only effectual means of extirpating it, as recorded a few years since in the *Annales des Sciences naturelles*, is to lay the fields under water for a considerable length of time, when the roots become completely rotted and changed into vegetable mould.

This remedy, however, can only be employed in the vicinity of streams, which, in Algeria, are few and far between." This species of Palm is of dwarf stature, being seldom more than 3 or 4 feet in height, unless the suckers are cut away, when the trunk will sometimes rise as high as 20 or 30 feet. It forms a roundish and tolerably dense head of fan-shaped, plaited, deeply-divided leaves, springing from a mass of coarse fibrous matter, which gives the stem a somewhat club-shaped appearance. This, as well as the general aspect of the plant, is well shown in our illustration. In this country it is quite hardy, in sheltered positions, as far north as Yorkshire, where I have known some specimens of it, planted out at the foot of a south wall, to stand for years without any covering whatever in winter. These specimens were exceedingly ornamental, and required no more attention than any ordinary evergreen. The comparative hardiness of this Palm, and the very effective contrast which its habit and foliage present to the shrubs usually planted in our pleasure-grounds (to say nothing of its tropical aspect), should recommend it to more extensive cultivation than it at present receives. Throughout the greater part of England it will be found a very effective addition to the margins of shrubberies, if planted in the south side, or in any tolerably well-sheltered position, where it will not be exposed to icy blasts in winter, or, at any time of the year, to such high winds as would tear and bruise its spreading leaves. W. M.

Chamærops humilis.

BULBOUS PLANTS.

Few classes of cultivated plants are so universally beautiful, or so much admired when in flower, as bulbs. They are, almost without exception, easily grown, and, when rationally treated, flower profusely; yet, we not unfrequently hear complaints that some of the commonest of them are shy bloomers, a circumstance, doubtless, attributable to some inattention on the part of the cultivator, rather than to any inherent defect on the part of the plants themselves. Plants to bloom in perfection, must be well grown and well ripened, and this is especially necessary in the case of bulbs. Nevertheless, nothing is more common than to see pots containing this class of plants, thrown carelessly under stages, or crowded on a shelf, and left

without moisture for days together, as soon as ever their floral beauty is over. Where mal-treatment of this kind is practised—and it is unfortunately far from uncommon—we need not wonder at bulbous plants not blooming the following season. When the season of flowering is over, such plants require even redoubled attention, and, if they are grown in quantity, they should be all set together, either in a small compartment by themselves, or on a stage in a Vinery or plant-house, where they can be readily seen and carefully watered and syringed as required. Bulbs, with the exception of what are called Dutch Bulbs, are not fashionable just now in the majority of gardens, although, in one or two places which we could name, they are a speciality, and a most attractive one. At Meadowbank, Amaryllises and other choice bulbs used to receive nearly as much attention as the Orchids, for which that place has so long been justly celebrated, and most amply was the attention just

alluded to repaid; for nowhere else have we seen such a fine show of Amaryllidaceous plants as was to be found in the conservatories of that northern Eden. We know of no other class of plants that would better repay any painstaking cultivator for his trouble, than hardy, half-hardy, and tender bulbs, collected, weathered, and well grown. Only give them positions equal to those occupied by Orchids and Ferns, with half the amount of attention that is usually bestowed on these plants, and we would have a perpetual exhibition of the most gorgeously-tinted flowers. We frequently hear it said, that no plants rival Orchids in delicate-tinting and delightful fragrance; but even the graceful Butterfly plants (Phalænopsids) with all their wealth of snowy blossoms, are not more beautiful, or more deliciously fragrant, than the chaste and pearly blossomed Eucharis. Place a blooming plant of the glowing Masdevallia ignea, or M. Veitchii, side by side with Hæmanthus coccineus, and ask an ordinary observer which is the brightest, freshest, and most effective. Take a handful of Ixias or Sparaxis from a warm sheltered border, and carry them into the vapour bath of an East Indian house, and they will hold their own against the most rare and valuable of tropical epiphytes. Indeed, Ixias, Sparaxis, Tritonias, and Babianas, either as pot-plants or in borders, are invaluable, and furnish abundance

of fine spikes for cutting and vase decoration. All they require is a rich sandy soil, in a sheltered sunny position, where their delicate flowers will not get damaged by high winds. Another bulb, worth growing by the dozen in every establishment where cut flowers or decorative plants are required, is the bright scarlet-flowered Vallota purpurea. This grows as freely as an Amaryllis, but differs from it in being evergreen; and not unfrequently inexperienced cultivators either ruin it entirely, or seriously injure it, by forcing it to rest for a portion of the year. This should never be done under any circumstances, or disappointment is sure to be the result. This Vallota, which is sometimes called the Scarborough Lily, is one of the finest of all bulbous plants for window culture in pots, lasting, as it does, a long time in bloom, and forming a very attractive ornament. Among the smaller bulbs adapted for general pot-culture may be named Tritonias, both white and blue forms; Narcissi, of all shades of

yellow and white; Crocuses; Snowdrops; and those most charming of all spring-flowering bulbs, viz., Squills (Scillas). We have seen some splendid potfuls of the golden-yellow Hooped-Petticoat Narcissus (*N. Bulbocodium*) this spring, and the tall blue *Scilla nutans*, growing side by side; and these, mixed with pots of Mignonette, Ferns, and other foliage plants, in a cool greenhouse, were strikingly effective. For autumn flowering, the Guernsey and Belladonna Lilies are invaluable, and their culture is as simple as that of the Hyacinth. Of these, well-developed bulbs showing flower-spikes may be bought for a few pence early in September, or as soon as they are imported by the nurserymen, and all they require is potting at once in any light sandy soil, and keeping them moist until their flowers expand; for window-culture, bulbs of this kind are specially adapted, and their delicately-tinted flowers shine and sparkle with crystalline brilliancy when placed under artificial light. For the decoration of the dinner-table, or for drawing-room vases, cut spikes or bulbs in small pots are specially adapted. During the coming season we hope to see both Guernsey and Belladonna Lilies imported in large quantities, and, as in the majority of cases, the flower-spikes are visible at the time during which the bulbs are offered for sale, their blossoming the same season may be relied on. As soon as the flowers are past, plant the bulbs in a warm sunny border, and, as a rule, they will again throw up their flowers the following year. The Belladonna Lily is specially adapted for outdoor or border culture; and treated in that way, it flowers freely every autumn; its delicate rosy-pink blossoms being borne on stout stalks 12 to 18 inches in height. Lilies are, fortunately, very popular just at present, and we hope they will long remain so, for as a class, no bulbous plants are more beautiful, either for pot-culture indoors, or for the decoration of beds and borders in the flower garden or pleasure grounds. B.

DENDROBIUM PIERARDI.

ALMOST everybody now-a-days who has the means—even where no special houses exist for their cultivation—is anxious to grow a few Orchids. Doubtless, the discovery that many of the most beautiful Orchids will flourish in a greenhouse temperature during a considerable portion of the year, and that they are not nearly so difficult to manage as was formerly supposed, has had much to do with their increasing popularity. Of course, comparatively few can afford to make a speciality of them, although, taking into consideration the high prices often realised at Orchid sales, they must, one would think, in many instances, prove a not unremunerative investment. For beginners, few families are more useful or beautiful than the Dendrobiums. *D. Pierardi* makes a beautiful basket plant, which may be had in good condition with as little trouble as many of the commoner creeping plants used for that purpose. We have a basketful of it literally covered with its soft velvety-looking flowers; it has been in this condition more than a month, and there are still many buds to open. Two years ago, when it was a very small plant on a block of wood, it was placed in a wire basket lined with Moss, and the interior of the basket was filled up with Moss interspersed with pieces of charcoal and two or three pieces of very fibry peat. The basket was hung up near the glass, and was well supplied with water during the growing season; afterwards it was rested by gradually withholding water and by exposure to the sunlight, not absolutely to dry it off so as to cause shrivelling. The great thing is to hang the plant near the glass, so as to get the growth well ripened. Where shall we find any stove or greenhouse plant that will yield as much floral beauty with so little trouble as the common but beautiful *Dendrobium nobile*? It may be had in flower at any season of the year where there are several plants in stock, by inducing them to make their growth at different periods; and, during their period of growth, heat and moisture are essential, accompanied by bottom-heat if possible. Much, however, of the success is due to the proper maturation of the pseudo-bulbs near the glass, altogether exposed to the sunlight, or at first with only the thinnest possible shade over them, to be removed altogether as soon as the plants get injured to the sun. I think this class of plants are often too heavily shaded, and, as a consequence, they do not flower so well. For the purpose of experiment, I placed a large plant of *Dendrobium nobile*, early in August, out in the open air at the foot of a south wall. My object was to see if exposure alone, even in a warm spot, without the aid of glass, would mature the pseudo-bulbs so as to produce a good bloom. The experiment, however, was a

failure, for the flowers are few and far between; whilst other plants placed on a greenhouse stage near the glass have flowered well. It appears that a plant that requires an Indian summer to mature its growth must in England have the aid of glass; but I know that many stove plants will flower all the better for being placed in the open air, in a warm sheltered place, for a month or so, to complete the maturation of their growth. E. HOBDAY.

Salvias.—When large conservatories and plant-houses are required to be kept gay during the dull dark months of the year, scarcely any subjects are more effective for mixing with the permanent inmates of these structures than these brilliant and free-flowering plants. There is a great variety of sorts, but, as so many of them are merely different shades of scarlet, I have selected a few kinds that will form a succession of bloom. I think I may, with certainty, select *S. splendens* as the best of all as regards freedom of bloom and intensity of colour. In these respects it is unexcelled by any plant with which I am acquainted, and from September to Christmas is its best season—although it may easily be had in bloom earlier and prolonged later if wanted. I also find *S. Heerii* a very distinct and good sort to succeed *splendens*, as its crimson flowers with white throat are very pretty. *S. gesnerifolia* comes in well in spring, and several other varieties; but, of course, the winter bloomers are the most serviceable. We always grow fresh plants every year, as they may be grown to any size in one season, and are particularly clean plants if kept growing freely with plenty of root-room and moisture. They are all best grown out of doors during summer, and removed under glass as soon as the nights get cold; for, although considered by some as old-fashioned flowers, they well repay all the care bestowed on them.—J. G.

Euphorbia jacquiniæflora.—During the past winter few plants in our stove have attracted so much attention as this. Three years ago I planted out a small pot specimen, and trained it along the back wall, along with the elegant *Ficus stipulata*. The plant took kindly to its position and grew very rapidly, making much stronger shoots than it ever does when cramped in pots; indeed, so robust were its growths that I almost despaired of their ever flowering. It did bloom, however; the tips of its shoots being glowing masses of bright scarlet, its colour being intensified by the fresh green *Ficus* behind. I prune them back close every spring, and this year the whole back wall has been one mass of scarlet and green. Some of the strongest shoots had flowers at their tips for 15 inches, forming the most charmingly natural of all floral wreaths, and these came in very handy for the drawing-room vases; and the smallest were occasionally used by the ladies, as a relief from Camellias and *Eucharis*, for their hair. The brightest arrangement I ever saw in a drawing-room vase consisted of two spikes of this plant, a spike of *Eucharis* bearing five open flowers and two pearly buds, this trio being further set off by just three fresh well-developed fronds of *Pteris tremula*. Nothing could be simpler or more striking than this, the whole being contained in one of the elegant trumpet-shaped vases recommended by your correspondent Mr. W. Thomson, at whose suggestion I purchased mine, and must say that it has saved the gardener many a pang of regret at the loss of his favourite flowers, since so few sprays suffice to fill them tastefully.—J. H., Sydenham.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Urceolina pendula.—This grows freely in my little plant stove and blooms freely every year. The only drawback connected with it is that it blooms after the leaves are withered, or just before they again appear, and this gives the plant a naked aspect. Judicious grouping along with Ferns and other foliage plants, however, to some extent obviates this defect.—J. M.

Camellia reticulata.—I am sorry to say that the fine specimen of this *Camellia* to which you allude (see p. 344) has been going back for these last few years. This season I have removed all the bloom-buds, and have also paid great attention to the nourishment of the roots; a course of treatment under which it is making some strong shoots, and has the appearance of regaining lost vigour.—C. A., Bank Grove, Kingston-on-Thames.

Fuchsia Insects.—I have sent you two insects which have been attacking a batch of young *Fuchsias*, and especially *Avalanche*. They eat the bark off nearly all round, just under the soil. What are they?—J. C., Pain's Hill. [*Otiorynchus sulcatus*. Familiar to most gardeners, being very destructive to Ferns in pots, eating the neck of the roots away under ground. They also attack Strawberries, Cinerarias, Saxifrages, and many plants with similar roots, and amongst others, the *Fuchsias*.—A. M.]

Lagerstroemia indica.—This is one of the chief ornaments of the garden and shrubbery in India, where it blossoms profusely, and where it is familiarly known as the Lace Flower, in allusion to the crisp wavy edges of the blossoms. Four varieties of *Lagerstroemia* are known to me, differing from each other only in their colours, viz., the rosy (as described in the *Revue Horticole*), a pure white, a fine lavender, and a deep purple, all kinds which group very effectively. Another species, *L. regina*, is a very handsome flowering tree, common in Bengal. Its flowers are similar in shape to those of *L. indica*, but about double the size.—SAMUEL JENNINGS, 53, Granville Park.

THE PROPAGATOR.

HOW TO MULTIPLY MAIDEN-HAIR FERNS.

ANYONE having a plant of Maiden-hair Fern, may increase it in numbers in a variety of ways. First, it may be increased by division; that is, by taking it out of the pot and breaking it up with the finger and thumb into several pieces, and planting each piece in a pot of peat earth, sand, and little boulders. Thus treated and placed in a warm greenhouse, the plants will grow away freely. Now is the time for such work, as the fronds are in a partially quiescent state, and many of the young ones are showing signs of growth. In this way anyone may triple their stock by the end of the season, and the plants will not be much less in size than if the original one had been undisturbed. Another way of increasing these Ferns is by means of seed or spores. If any have been disappointed with the result of sowing the spores, the better way now to do is to have a few broken bricks, and some peat and sand sparsely introduced among them on the beds or tables upon which the plants stand. Allow the fronds to distribute their own seed; do not disturb the surface immediately around them, and there will spring up dozens of plants. Success may thus be counted upon, not only in the case of Maiden-hairs, but, also, in that of almost every description of Fern.—*Farmer.*

Rooting Cuttings in Coke Dust.—I have often proved that cuttings of soft-wooded plants that are very liable to damp off may be struck with greater certainty in charcoal or coke dust than in the usual way in sand. It imparts a greater porosity to the soil, damp cannot lie about the base of the cuttings, and there is less danger if an inexperienced hand does the watering. Amongst other things we have this year struck our spring stock of Tricolor Geraniums in coke dust, and we have certainly never had more success. It is not a bad substitute for sand, for covering very small seeds in spring of tender annuals that are usually sown in pots, pans, or boxes, especially if there are any snails or slugs in the immediate neighbourhood; they will not travel over it. I should explain that what I mean by coke-dust is simply the dust taken from the coke heap, and which afterwards passed through a very fine sieve to free it from all coarse particles.—*E. HOBDAY.*

Layering Magnolias.—In nurseries, Magnolias of all kinds are commonly propagated by means of layering. This operation is commonly done in September and the first part of October. Bushes planted in the open garden, or at the foot of walls, may all be treated alike. Before commencing to layer the shoots, cut out any that are not required, or are in any way so deformed as to prevent their being layered successfully; never leave a single shoot above 15 inches in length unlayered in open borders, but those at the foot of walls may be allowed to retain a few shoots nailed thereto, but none hanging loosely about. The ground should also be loosened, and a little prepared soil got in readiness, which may consist of any good potting-soil mixed with a little peat and sand; but a good fresh loam, mixed with silver-sand and peat, is the best. Bring a basket with you in a basket or barrow, also some good strong wooden hooked pegs, to the plants to be layered. Bring down the longest and strongest plants first, and a little nearer the apex than the base of the shoot—say, two-thirds of the length from the root—remove the lower leaves, and make an incision under an eye to half through the stem, and cut upwards to a little above the eye, so that the longitudinal cut may be an inch or an inch-and-a-quarter in length. Without drawing out the knife, give the end portion a slight twist at the incision, so that it may assume an upright position when layered. Then, having made a cleft in the soil about three or four inches in depth, place therein the layered shoot, and around the cut handful or two of the prepared soil should be placed, and the whole made firm and level. The shoots must be fixed in this position by strong pegs, which should be placed near the base of each shoot, as the greatest pressure is near the parent root. The point of this shoot should then be cut off, and the several small side branches layered in the same way. The next strong branch should be taken down and layered in the same way until the whole are gone over. The smaller ones are then layered, as are also all the side branches of the main shoots. Sometimes there is a general overcrowding, but a skilful workman could avoid all this, and fill up all empty spaces neatly and quickly. Two workmen, acting together, go over a much larger space in proportion, and perform their task better and more satisfactorily than one. Only the stronger points of the shoots could be cut off. The plants are allowed to remain in this position for two years before they are disturbed. They are then lifted, planted into nursery lines, or else potted. In some instances, wooden skeleton frames are placed over the Magnolias after they are layered, by which means, and a few mats, they are partially saved from the winter's severity.—*WM. FALCONER.*

THE FLOWER GARDEN.

DAHLIA CULTURE.

DAHLIAS may be propagated by means of cuttings, layers, root-divisions, or seeds; the latter being only used where new varieties are a desideratum. Cuttings are, undoubtedly, the best means by which Dahlias may be increased, and by these they may be multiplied to any extent; division of the roots is very commonly practised, but cuttings are, as I have said, the best. When propagated by division, the tuber or tubers left, if they survive the summer, generally decay when stored, and communicate disease to the young plants. When cuttings are used, each has its own self-formed tubers, and they are, on that account, less liable to rot during the winter. If started in February, in a temperature of 65° or 70°, each crown will produce three or four cuttings every two or three days; which may be taken off even as early as March, removing them close to the crown, but taking care not to injure it, as others will come up at the base of those removed. It is, also, necessary for the growth of good plants, not to let the cuttings become too long before taking them off the parent tubers, as they are more apt to lag, need more room, and are not so convenient to plant out as short cuttings. When the crowns have supplied all the cuttings that can be got from them, they may then be divided, if required; consequently nothing is lost. To propagate from layers, the lowest branches of the plant must be taken as early as possible, and should be pegged down in the soil, in which, if of a sandy nature, they will root freely; in the absence of sandy soil, a quantity of leaf-mould, with a good admixture of sand, may be laid down for them to root in. Pure white sand alone I find to be best suited for striking them in, and a mixture of leaf-mould and sand is very good for starting the crowns in. Cuttings may be successfully struck during the summer months; but this is seldom done, except in the case of choice varieties. Three-inch pots are well adapted for putting the cuttings into, six cuttings being put in each pot, which should be plunged in a brisk bottom-heat, covered with hand-glasses, and shaded from bright sunshine; in less than a fortnight they will all be rooted, and may be potted off singly into large 60-sized pots, which may be put into lower temperatures gradually, until, say, the 1st of May, when they may be put out of doors until required for planting. It is necessary for Dahlias, as well as for other tender bedding-plants, to have them in a situation where they may be easily protected in case of frost, as, in the event of the thermometer getting as low as the freezing point, they would be greatly injured, if not killed outright. Dahlias are seen to most advantage when planted in masses in large beds. For this purpose the tallest should be collected for the centre or background, as it may be, mixing the colours as well as possible. They should be planted 3 or 4 feet apart, and, as they advance in growth, all the lower branches cut off about a foot from the ground. When a shrubbery is in any way unsightly, and has a border in front, a row of Dahlias often sets it off to advantage; and I have also seen a ribbon-border backed by Dahlias with good effect. Staking and tying out the shoots must be particularly attended to, as the stems are very brittle, and break under the least wind-pressure. Earwigs are great enemies to Dahlias, but they may be trapped by using small round troughs, which may be procured at any pottery. They may also be caught in pieces of Hemlock stems, 6 inches long, leaving a joint on one end, and sticking the pieces here and there through the Dahlias. Small pots, with a little bit of dry Sphagnum Moss inside, inverted on the tops of stakes, likewise form good traps. As regards stimulants, manure-water of the strongest character may be safely used after the plants show flower, provided it be administered in the evening. Some Dahlias will produce all their flowers, or nearly so, perfect; others require their shoots to be well thinned, and all blooms, except three or four, to be cut off in order to be eligible for show purposes; but, as a general rule, all may be more or less thinned. Dahlia roots have kept well, and flowered for years in succession, in dry soils especially, when the plants have been cut down to the ground, and covered with any material that will protect them from frost.

JAMES MORRISON.

Wotton Gardens, Aylesbury.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Mossy Group.

S. perdurans Kitaibeli.—For many years, in fact, almost as long as I can remember, a Saxifrage of distinct habit and appearance has been in cultivation under the specific title of *pulchella*, not unfrequently also named *controversa*; the latter, however, is evidently a misnomer, as the plant bearing that name belongs to the small group of annual Saxifrages, with one of which, *S. tridactylites*, many will be familiar as growing on the top of old walls, the former name I can find no authority for whatever, and, after a careful examination of the plant, I find it answers the description given by Engler of *S. perdurans* in everything, except one trifling omission, namely, the slender ciliated hairs that occur on the foot-stalk of each leaf, and which I think it highly probable would vanish in the process of drying; under this name, therefore, I propose describing it. In general appearance the plant is dwarf and caespitose in habit; the rosettes, medium-sized, of a beautiful dark shining green, remarkably equal and regular in development; the leaves, individually, are thick and fleshy, five-cleft, the divisions tolerably equal and rounded at the points; the petiole is dilated and margined with long slender ciliae, except which, the surface is perfectly glabrous; the flowers are large, pure white, supported in pairs, or, sometimes, solitary, on peduncles about 3 to 5 inches long; the bracts are foliaceous, either three-notched or entire; the calyx lobes are obtuse, and the petals broadly obovate. As a species it is perfectly distinct, and retains its character true from seed; it is of free growth, thriving well either under pot-culture or in the rockery. Its native habitat is limited to Croatia and the Carpathian Mountains. *S. Wahlenbergii* of Ball, which, I believe, I have met with in some collections, is synonymous with the above.

S. pubescens of De Candolle is a dwarf-growing trailing species, deriving its well-marked specific title from the fact that the whole plant is suffused with a short pubescence that gives it a greyish-green aspect. Its leaves are generally more or less entire, lanceolate, slightly incurved at the point, concave above and sessile; the margins also entire, with a few short hairs; the points of the leaves are acute but not mucronate; the flowers are produced in twos or threes on a foot-stalk about 3 inches high, they are comparatively small, of a creamy-white colour. A native of the Pyrenees, and considered by some authors as a variety of *exarata*, from which it differs decidedly in its creeping habit, besides other particulars.

S. trifida of Haworth is looked upon by Engler as a synonym for one of the many varieties of *decipiens*; but, as I take the latter species as including only those in which the five or seven-cleft arrangement of the leaves predominates, if, in fact, it be not an absolutely essential character, whereas, in this species, as its name indicates, the leaves are always trifid, hence, I deem it desirable to retain Haworth's original name. This, I am the more disposed to do, seeing that it has held its distinctive character under cultivation extending through a long series of years. It is of a creeping habit, though by no means so much so as in the *hypnoides* group, which will immediately follow. The leaves are distinctly divided into three short lobes, well defined and separate from each other, acutely pointed, but not mucronate. Each leaf is supported on a foot-stalk nearly twice the length of the blade, with a few scattered marginal hairs. The flowers are small and somewhat pendent. It is a native of the Vosges and the Pyrenees.

The Hypnoides Group.

S. hypnoides is the typical species under which are grouped all the forms and varieties of our British Saxifrages whose leaf divisions do not exceed three in number. It grows abundantly in most of our mountain districts; and, setting aside those variations induced by peculiar circumstances of soil, exposure, and locality—which, however marked they may be at the time of collecting, are apt to disappear during the second season of garden culture—I say, setting aside these which lack permanency, there are many forms which years of culture have failed to alter, and which we must consider as well-established varieties. Before dealing with them, I must add a few words of description as regards the type itself. It is a procumbent trailing plant, generally speaking, of lax growth; its radical leaves are all distinctly three-cleft, each division terminated with a bristly point. The foot-stalk is longer than the divided blade of the leaf, and is fringed with hairs, which assume, towards the base, a long slender cobwebby appearance. The flowering branches are slender, each supporting three to five white erect flowers; the floral leaves are linear, and not unfrequently entire. It is an old garden favourite, where it forms great cushion-like masses, fringed around with its trailing stems, growing freely and flowering abundantly.

S. hypnoides var. densa, an exceedingly diminutive form, dense and compact in growth; the leaves as frequently linear as

trifid, the segments very narrow, and the flower-stems rare exceeding 2 inches in height. Cultivated, to my knowledge, for quarter of a century, and still the same.

S. hypnoides var. Whitlavii.—Equally diminutive as the above; leaves always trifid, rarely producing flowers at all; its growth is perfectly flat, forming a lovely light green carpet, and hence admirably adapted for an edging plant, to back up a stone or terra-cotta margin to a flower-bed. We have used it here for the purpose for years; the absence of flowers renders it so much the more valuable. In spring gardening, it forms a beautiful emerald ground-work for dwarf Tulips, and other bulbs, retaining its bright green colour through the winter. This identical variety I picked up when a lad, on one of my very first botanical excursions on the Mourne Mountains in the north of Ireland, and named it after Mr. Whitlaw, the then president of the Botanic Gardens at Belfast. I may, therefore, state that its constancy has been tested through a long series of years, and under diverse circumstances, without indicating the slightest variability.

S. hypnoides vars. leptophylla, lanceolata, and flavescens, are three very slender-growing forms, viewed by some authors as distinct species. *Lanceolata* I found on the Pentland Hills, and it still retains its original character—namely, the undivided leaves; but seedlings raised from it do not. In *flavescens*, the flowers are solitary, on short foot-stalks, and have a slight tinge of yellow; hence the name. I might incidentally remark that all these varieties are slightly affected by that midsummer hybernatory character that we shall presently find in most of the species that affect the south of Spain.

S. hypnoides vars. arranensis, atrovirens, and elegans.—These varieties are distinguished from the previous group by much denser habit of growth, and general tufty, not trailing, character, so much so that, were it not for the constancy of the trifid character of leaf, I should be disposed to have referred them to the caespitose group. The first variety was picked up in the Island of Arran by a non-botanical friend, who admired it for its dense dark green appearance, which it retains unchanged. The same remark applies to *atrovirens*, as the name indicates; but the leaf divisions are narrower than in the first variety. The last in this group has long slender foliage, which gives it a markedly elegant appearance; hence the name.

S. hypnoides vars. recurva, hirta, incurvifolia, and elongella.—These four varieties, may, I think, be considered to complete the goodly number of variations that are of a sufficiently constant character as to require chronicling at my hands. *Recurva*, as might be inferred from the name, has all its leaves, as they occur in the rosettes, slightly bent backwards; their segments are very slender, and its lateral extension is confined to very short stems. On the other hand, *hirta* and *incurvifolia* are remarkable for the rosettes of incurved leaves, more obtuse at the points than is usual in the *hypnoides* section, and occasionally diverging therefrom in the five-cleft character of the leaf. Neither of these varieties are trailing, and I have had great difficulty in determining in my own mind as to whether they are correctly classed under the present group, occupying, as they do, a sort of intermediate position between this and the next. The same remark applies to *elongella*, but in a less degree, as in it we have the mucronate terminations of each of the leaf divisions, which are, if not altogether absent, at least considerably modified in the two previous varieties.

S. caespitosa of Koch I take as the representative type of several so-called distinct species, which I purpose considering as varieties. Engler, I see, merges this specific title into a synonym for *decipiens*. It appears to me, however, that all the variations which he enumerates, naturally group themselves under two heads. I purpose, therefore, considering these two species as distinct, and grouping the variations, according to their respective affinities, under either one or the other. This species is chiefly distinguished from *hypnoides* in the fact that the leaves are either five or seven cleft, each division being broader and more or less blunt at the apex. The foot-stalks of the leaves are shorter, and the marginal hairs thereon stiffer and more erect. The growth is, to some extent, procumbent; the sterile stems soon, however, forming large rosettes. The flowers are arranged in lax cymes, numbering five to eight in each inflorescence. Geographically speaking, both *caespitosa* and *decipiens* appear to claim a home in the northern regions of Europe and America; rarely are they met with south of the mountainous districts of central Germany. Some of the forms are found in Ireland and Scotland. They, however, occur most abundantly in Iceland, Greenland, and even as far north as Spitzbergen.

S. caespitosa vars. laxa and groenlandica.—The former, as the name indicates, is remarkable for the lax or scattered arrangement of its flowers, the foot-stalks being long, also for a remarkable

breadth in the divisions of its leaves; more especially is this noticeable in the caulinary bracts: the latter is a dense-growing compact form, presenting in its appearance all the stunted characteristics that one might expect as coming from such an inhospitable climate as Greenland's Icy Mountains" are likely to offer. In this form the flowers are usually produced singly on short foot-stalks, and the whole plant is less hairy than in the former variety.

S. cæspitosa vars. platypetala and Stansfieldii.—Both these are British varieties; in the first the numerous short procumbent stems give it a very distinct character, added to which we have larger flowers and broader petals, as the name indicates. In the second the general growth is more truly cæspitose, the flowers smaller, the dark-coloured sepals supported on short peduncles; the whole plant has a dark green colour, whereas *platypetala* is light green.

S. decipiens of Ehrhart may, in general terms, be said to include a number of hairy forms, in which the procumbent character is altogether absent. The leaf divisions in the early stages of development, present the three-cleft arrangement, but, as the rosettes reach maturity, they assume their true character, and become five- or even, sometimes, seven-cleft, by a further sub-division of each of the lobes.

S. decipiens vars. major, Webbiana, and villosa.—The first of these varieties is a very distinct plant which I got from the continent many years ago under the name of *hypnoides*, collected in one of the islands in the Baltic; it is however, evidently nothing more than a large and hairy form of *decipiens*. The other two varieties are less hairy than the typical plant; the leaf divisions are also more crowded, and, in the last variety, are more compact in their arrangement in the rosettes.

S. decipiens vars. spongiomica, Sternbergi, and palmata.—Of these three varieties—in the first, the leaf divisions are almost linear, the flowers are smaller, and the whole plant less hairy than in the other two; these are very closely related, but, in *palmata*, the leaf divisions are shorter and blunt at the point; the petals of the flowers are also smaller than in *Sternbergi*, and are very distinctly three-nerved.

S. palmata of Panzani, though looked upon by Engler as a mere variety of *decipiens*, is, I think, an unquestionable claim to specific distinction. It possesses a singularly diffuse habit of growth, forming very large rosettes of somewhat fleshy, loose, nearly glabrous leaves; the flower-stems are perfectly smooth, each carrying from five to eight blooms; individually, they are fully twice the size of those of the preceding species; the petals being broad, rounded at the point, and tapering so slightly that they overlap one another, thus giving the flower a perfectly cup-shaped appearance; of pure white, in the bud, the sepals are tinted with a shade of chocolate-brown, and, in that state, the petals also are suffused with a tinge of pink towards the tips, giving the buds somewhat the appearance of the unexpanded flower of the Daisy. As a species, this is perfectly distinct from the *palmata* of Smith, found in the south of Ireland, and is preferable to that form of *decipiens* known as *Sternbergi*. I am not aware that there is any record of a native habitat for this plant, but those who cultivate it will fully endorse my remark, when I say, that it is one of the showiest and most distinct in this section, and well worthy of receiving its true status as a distinct species.

MANUFACTORIES MADE PICTURESQUE.

WHEREVER trees will grow—and there are few places where they will not—an agreeable landscape may be produced, even in conjunction with the most unpromising kind of architectural structures. In the present example, something in that way, as will be seen, has been attempted; but enough has not been done to ensure success. The building is an important one as regards dimensions, and the architecture is far from mean in character; but, what with the tall chimney, and the masses of

workshops in the rear, a far greater amount of partial concealment is rendered desirable, if it is hoped to render the building and its surroundings picturesque. There is a tolerably well-shaped pond with nice tufts of Sedges, which, as they extend, will break the hardness of the outline, and render it a good feature; and the mass of rock-work which rises from one side of the water is not of the usual patchy kind, but massive, well designed, and of considerable extent. The failure consists in the paucity of trees. There are only two of any considerable size, and they prove quite insufficient to break up the monotony of the obtrusive lines of the building, or to conceal the ugly chimney. More trees near the tall one to the left, and two or three others near the palisades, would so veil the comparative ugliness of the building with the beauties of foliage, that the glimpses of some of its best features, which would necessarily still remain visible, would be of positive advantage to the aspect of the garden landscape that might be thus obtained. Horizontal lines are always pleasing when seen among the irregularities of natural forms. This principle is well understood in France, where many large industrial establishments, such as the great cotton factories in the neighbourhood of Rouen, are made very attractive by means of trees, and by well-designed approaches, in which they play a principal part; while the additional attraction of flower-beds is in many cases superadded with excellent results, in imparting to

many of these palaces of labour a fresh, healthy, and cheering character. If we ornament triumphant toil with fair surroundings, it only receives the embellishment which it naturally calls for; while vast industrial structures, without such care, cast, as it were, a shadow of depression, which is not in accordance with the character of well-paid and productive labour. The surroundings of many of our own largest and most important industrial establishments are not only little cared for in this respect, but any attempt to beautify them is scarcely thought of; and, so far from being picturesque, in the very mildest sense of the term, they are too often absolutely squalid in their aspect, and convey the idea of prison-houses of compulsory toil, rather than, as they should do, grand centres of free and re-

Trees as a means of improving the aspect of a manufactory.

munerative labour willingly undertaken, and in which the honest pride of success would be far more enjoyable if the arena of its development were rendered more attractive. Of course, this is not always practicable; but, whenever the artisan can be enabled to proceed to his workshop along a pathway decorated by flower-beds, or beneath an avenue of handsome trees, these agreeable adjuncts ought to be provided, as certain to produce a pleasant, cheering, and refining impression, and enable him to go to his work in a better and happier frame of mind. The beautiful task of the horticulturist is only beginning. It has, as yet, been confined in its labours to the homes of the rich. It has yet to embellish and render attractive the great structures devoted to labour throughout the land; and is as imperatively called upon to impart a pleasing aspect to the homes of our workers, as our builders and architects are to render them healthy by good ventilation and efficient drainage. H. N. H.

CHINA ASTERS.

Of these, we have two main divisions, the German and the French. We apply the definition German to the Quilled varieties, i.e., to those having tubular or quilled florets, though this is somewhat restrictive in its application, as the German growers have, of late years, done much in the way of improv-

ing the flat-petalled varieties also. The French Asters, which have large flat florets, are so named because French florists took them in hand some years ago, and effected in them a great and marked improvement. Taking the Quilled type as representing German Asters, it must be stated that, notwithstanding that the Germans have grouped them into many assumed types, yet but few of them are worthy of cultivation. What are termed Hedgehog, Porcupine, and other Quilled forms, are of a poor and worthless character. A really good strain of Quilled Asters furnishes very beautiful flowers; the form of the flower is half a ball of quilled petals, and many charming hues of colour are found among them. Of imported Asters the best types are the German Quilled and Reid's Quilled. Fine strains of Asters are also grown in England; and it is not too much to state that these, when well-grown and selected, are better than imported German ones. German Quilled Asters require special treatment to bring out their full beauty. A fine strain, if subjected to ordinary border treatment, will prove disappointing. They are, therefore, less valuable for ordinary border purposes than the flat-petalled types; still, neither Reid's nor the German Quilled should be cultivated in pots, as they have a somewhat lanky growth, and especially as there are dwarf-growing varieties of the flat-petalled section much better adapted for the purpose. If it is required to have a few fine Quilled Asters for show purposes, a well-manured bed should be specially prepared for them. A few plants taken from the seed-beds should be grown on in pots in some light rich soil, and planted out in lines towards the end of May, if possible, after a genial rain. They should be watered in dry weather, and encouraged in every way to make strong growth; the soil about them should be occasionally stirred, and it should also be mulched with some decayed manure from a spent hot-bed that will readily crumble to pieces, or which has been lying aside for use for months. In order to get fine flowers, all, except four or six buds, should be removed in order to induce fine development; and, as the day for showing draws nigh, some protection from sun, wind, and rain must be given to the flowers, or they will be wanting in that fresh clean appearance that so readily strikes a judge's eye. In all gardens where cut flowers are in demand, a bed of Quilled Asters should be grown to cut from. Only let the soil be rich, and the plants may be allowed to carry all their flowers. Such a bed of Asters will yield a large quantity of blooms for many weeks. A few for decorative purposes should also be planted about the mixed border, or any suitable spot where they can be seen to advantage.

Passing now to the flat-petalled or French section, it may be stated at the outset that its varieties are legion, but that a large proportion of them are worthless. One of the best forms of French Aster is Truffaut's Pæony-flowered Perfection, which bears noble incurved vari-coloured flowers. This is the French Aster *par excellence*, and though it is now offered by Continental growers in a bewildering multitude of varieties, the type I have named will give most satisfaction. Its flowers are large, full, with petals folding inwards—incurved, as it is termed. My next favourite type is the Victoria. This is of shorter and rather more upright rigid growth than Truffaut's Pæony-flowered, and has very large, full, flat-petalled flowers, but the petals lie outwards, or are reflexed. This is a magnificent Aster, with splendid full flowers like half a ball, and they assume a fine variety of colours. If any evidence were wanting of the popularity of this type, it may be found in the fact that it is fast taking the place of Truffaut's for show purposes. There is one good quality common to both these types, and that is, under ordinary border treatment, they will produce good flowers. They deserve, however, to be well treated; and, if planted in rich ground, and given a little manure-water at the blooming season, splendid blooms will reward the cultivator. If required for exhibition, there must be some disbudding in order to get increased size and fulness. The dwarf Chrysanthemum-flowered is a somewhat peculiar type, producing large blooms like those of a reflexed Chrysanthemum, and flowering later than the two before-mentioned types. Having a very dwarf free-branching habit, it is well adapted for flowering in pots, or for use as an edging to a bed of taller-growing kinds. The flowers of this type may be used for show

purposes, but they cannot be compared as regards quality with those of the Victoria Aster. It should be stated that there are many varieties of the above type offered as novelties, as cellular, quilled, and porcupine. To these names are appended the new Humboldt, the newest Bismarck, the newest Shakespeare, &c.; but they are all of an inferior character. The Crown-flowered or Cocardeau Aster represents a very distinct and charming type, and is so named because of the flowers having a central disc of white, with a margin of blue, lilac, carmine, crimson, and other shades. This is a selection from the Pæony-flowered Aster; the florets are reflexed, but the flowers are not so large and full as those of the Victoria. There are yet two pretty dwarf forms of Aster that I especially commend for pot-culture and for small gardens. They are the Dwarf Pyramidal and Boltze's Dwarf Bouquet. There is not a great deal of difference between them, but still enough to make the cultivation of both desirable. Very dwarf in growth, and very free in flower, they produce a profusion of nice flat-petalled, vari-coloured blossoms, and are unequalled to cut from. They are well adapted for indoor decoration before the Asters grown in the open ground come into flower. There is no difficulty in raising Asters, provided the seed be good; at the same time, Aster seeds are somewhat fickle in the matter of germination. They may be sown in pans or pots, or in shallow boxes, in a rich light soil, and placed on a warm shelf in a greenhouse and kept moist; or they may be sown on a soil-bed in a conservatory; or in pots placed in gentle heat in a Cucumber frame. As soon as they are large enough to handle, prick them off into other pots or boxes, and encourage them to grow fast and vigorously. Asters should be treated well—i.e., they should have rich soil and adequate moisture—and they will yield an abundant supply of flowers. The seed may be sown now.

R. D.

Plants now in Bloom on the Root-work at Weybridge.

—Your engravings of the root-work plants have been much admired; and, let me tell the talented artist that his hints on grouping plants, blooming at the same time, with a view to pictorial effect, have not been lost sight of. Among the beauties now out are *Æthionema coridifolium*, *Dianthus glacialis*, *Gentiana verna*, *Narcissus juncifolius*, *Scilla italica*, *S. amœna*, *Uvularia grandiflora*, *Trillium grandiflorum*, and *Epimedium rubrum*. This season, frost has spared *Dielytra spectabilis*. Among the strong-growing carpeting plants, we find most useful the old *Lithospermum prostratum*, *Achillea Ptarmica*, *Waldsteinia trifoliata* and *geoides*. These are now out. *Gaultheria procumbens*, with its beautiful red berries, grows best among roots. It makes its way between the bark and the wood in the wildest, prettiest manner. Among Saxifrages, most of them with their white flowers, are *S. Cymbalaria*, with its yellow, and the mossy *S. atropurpurea*, with its pink, blossoms, both of which have a very good effect.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Anemone Robinsonii.—Three years ago I got a beautiful *Anemone* under this name. It resembles a large wood *Anemone*; the sepals are a delicate lavender, the anthers golden. It is a very free bloomer. Can any of your readers say what its origin is, or whether it is a species or a variety? It is one of the best of its class.—SALMONICEPS.

Doronicum austriacum.—Is this only another name for *D. caucasicum*? The latter is now finely in flower; it has a dry habit and is a free bloomer.—OBSERVER. [The plant alluded to by us (see p. 322), as *D. austriacum* is usually known by that name; it differs from *caucasicum* in being a stronger grower, and in its flowers, which are nearly twice the size of those of *caucasicum*.—ED.]

Doronicum Clasii.—I grow upwards of a thousand hardy plants in my garden; and, at the present moment, this *Doronicum* is pre-eminently the most showy. It grows about a foot high, and a plant of it (not a very large one) has on it twenty-seven large golden flowers, and many more have yet to open, making it altogether a very desirable plant. The little *D. caucasicum* is, of course, over. What a lovely little thing this is for early spring, even before flowering! The tufts of its leaves alone are remarkably handsome.—THOMAS WILLIAMS.

Orobis vernus.—This is now flowering freely, both in the open border and also in pots in the greenhouse, in which it forms an attractive object associated with *Narcissus*, *Muscari*, *Primroses*, *Squills*, and other spring flowers. How is it we so seldom see *O. luteus*, another free-blooming plant, which bears blossoms as large as those of *O. vernus*, but of a rich orange-yellow colour, in cultivation? Both are readily propagated, either by means of division or seed.—B.

Santolina incana.—This is one of the neatest and prettiest of all silvery plants for edgings or carpet beds. I have a quantity of it in a frame in shallow pans, and I find that it may be increased freely from cuttings taken off like those of *Cerastium tomentosum*, and struck in sandy earth. I had at first only a small pot-ful of it, but I have now at least 500 pretty little plants of it in thumb-pots, which will be ready for planting outside in May or June. It contrasts well with dwarf blue *Lobelia*, or crimson *Alternantheras*.—J. M.

THE FRUIT GARDEN.

GRAPES IN WATER BOTTLES.

THOSE who a few years ago, when this system was first promulgated, were so loud in their denunciation of it, must be surprised when they find that at the last meeting of the Royal Horticultural Society old Grapes of Lady Downe's were considered superior to new ones of the Black Hamburgh. I give no opinion on this matter, but as one who does not think very highly of Lady Downe's, except for its keeping qualities, I should have thought that equal first prizes, or a division of the first and second in equal proportions, would have met the exigencies of the case in a more equitable manner. Be that as it may, there can no longer be any dispute that we have Grapes, which, under proper treatment, will keep for an almost indefinite period. Calling the other day at Sherborne Castle, I saw in the fruit room there some cores of bunches of Lady Downe's, as fresh, crisp, juicy, and free from shrivelling, as if only just cut from the Vine. These were removed in October, have been kept in water since, and promise to remain in their present plump condition until midsummer, if not longer. Until within the last two years, Mr. Pragnall, the enthusiastic gardener there, used to leave the Grapes upon the Vines until the new year, but he found so much inconvenience from the Vines bleeding, and they became so weakened in consequence, that he was obliged to abandon the practice, and is now reaping the benefit of the change. In addition to Lady Downe's, Mr. Pragnall grows for keeping purposes a house of White Muscat, and another of black or Mrs. Pince. Both these keep admirably in water, but are not quite so free from shrivelling as Lady Downe's. There are several other Grapes quite as good in their keeping qualities as Lady Downe's, as, for example, Oldacre's, West's St. Peter's, Gros Colman (the largest and handsomest of all the late Grapes), the Syrian and the White Nice, both remarkable for size of bunch, and, when properly grown, exquisite flavour, but, to secure that end, it is necessary that they should be grown in a Muscat temperature. Give them that advantage, and you will have no cause to complain of deficiency of flavour. The coming Grape for early spring work will probably be Pearson's Golden Queen, which, with a handsome bunch, brilliant orange berry, and delicious flavour, promises to be the Grape of the period. I trust, also, that having a dash of the Strawberry Grape in it, it will be found constitutionally better suited to our climate than some of its more recent rivals.

A.

FRENCH MODE OF GROWING MELONS.

THE cultivation of Melons is one of the most profitable to market-gardeners, and, consequently, demands very great attention. The varieties grown are the white-bottomed Cantaloup Prescottt, the orange or black Cantaloup des Carmes for the early crops, and for the succeeding ones, the dark grey, the scabby, or the large-ribbed, as may be found most suitable. As heat is necessary for growing Melons, it is generally furnished by manure. The few market-gardeners who have a hot-water apparatus, succeed equally well in that way, but it is far more expensive. The earliest Melons are sown in January in a very warm hot-bed under a frame. Three weeks after sowing, fresh beds are made in the same manner, and covered with frames and lights. In these the Melon plants are transplanted, 120 to 130 under each light. They should be well covered at night, and the frames should be lined with warm manure when necessary.

In May, fresh hot-beds are made in trenches, 4 feet 4 inches wide; the alleys are made wider than in the other beds, and are filled with a mixture of new and old manure, to which new manure should be added whenever the temperature requires to be raised. On these beds is placed a layer of soil, from 6 to 8 inches deep; this layer is to be level in the beds, but, in the trenches, raised in the middle. If the manure is dry, it should be previously watered and trampled. The frames and lights are then placed in position, and, when the ground heats, the plants are put in, either without breaking the

balls or otherwise. The latter method, carefully done, is the best in our opinion. The plants root sooner after a slight pressure of the earth around the roots, followed by a gentle watering. The fibres of the roots develop themselves at once after this treatment, while they remain dormant for some time if the ball be unbroken. Both methods, however, have their advantages. The young plants should be kept in the shade, and not planted too deep; an inch or two of the stem being left between the surface and the two shoots. The lights should be covered with mats at night, and also shaded during the day. A week after planting, the alleys are furnished with manure, which should be turned over at the end of a fortnight, and fresh manure added, if the temperature requires it. The plants should be pinched back to two buds; these will form two shoots or branches. After a fortnight, the frames are examined one by one, and the cotyledons and bad leaves are removed. Another inspection is made a week after, when the two branches are spread out, and the shoots, which are directed against the sides of the frames, are cut off. After another week, a third inspection is made, and superfluous shoots removed. At this time the plant should have filled its light, be in full flower, and even show some fruit; the shoots should now be pinched back so as to leave only one or two buds beyond each fruit. At the fourth inspection, which is made in another week, everything should be cut away beyond what serves to furnish the light, including those fruit which are not intended to be kept. The fruit that are retained should be shaded by the leaves, and placed in such a position as not to rest too much on the bed, but, as much as possible, on the stem. Only one Melon should be left on each plant. Air should be given, sometimes at one side and sometimes at the other, and gentle waterings whenever necessary. At the fifth inspection, any fruit that requires to be removed should be cut away, and all the shoots pinched back to two buds. The little Melons, which, if left, would spoil the fruit selected to remain, are not lost by being cut away. They are in great demand with the pickle-makers, having a much finer flavour than Gherkins. When the fruit at first selected to remain turns out badly-shaped, it is wise to cut it away, and allow one of the younger fruit to grow in its stead. It sometimes happens that a young fruit will grow unperceived, notwithstanding so many inspections; if, when it is discovered, the principal fruit is three-fourths grown, the other may be left untouched, as it will then do no harm. The Melon is known to be nearly ripe when it gives out a peculiar odour, when the rind assumes a yellow tint, and when the stalk curls. The crop is ready for market, according to the temperature, &c., in the end of May and the first fortnight in June. The greatest care, however, will not always succeed in bringing in a crop as early as desired. Market-gardeners do not gather their Melons when quite ripe. As soon as the fruit present the marks of incipient maturity which we have just mentioned, they are cut and placed in a cellar to retard their ripening. If this were not done, the Melons brought to market the day after being gathered would be already stale.

The Melons of the second season are sown in February, transplanted in the beginning of March, and planted out in the early part of April, just in the same manner as those of the first season. At this period, instead of raised hot-beds, trenches are made, not more than $3\frac{1}{4}$ feet, nor less than $2\frac{1}{2}$ feet wide, and 1 foot deep; these are filled with a mixture of new and old manure, well trampled and watered, and covered with a layer of soil 8 or 10 inches thick. The kinds grown at this time are the White-bottomed and Grey-bottomed varieties. The pinching, watering, and other treatment, are the same as before, subject to the difference in temperature. The crop comes in in June and July.

The Melons of the third season are sown in March, transplanted at the end of the month, and planted out in the end of April. The crop comes in about the end of July. The treatment is the same as before.

The sowings for the fourth season are made in the end of March, the seedlings are transplanted from the 8th to the 20th of April, and planted out from the 1st of May to the 10th of June. The greater part of the Melons of this last season are planted out on old hot-beds, in which Carrots have been grown. These beds are turned over and some fresh manure added. The added

manure must be watered, if dry. The crop comes in from the end of August to the beginning of September. Melons, at all seasons, require frequent gentle waterings before planting out, and the surface of the soil should be mulched. In the last season, the plants are grown under cloches. The kinds then grown are the Seabby or Wrinkled varieties.

In growing the first season's Melons, those frames are used which have previously served for Lettuces. In the second season, we use the frames which have been removed from Carrots in the beginning of April. In the third, those from Lettuces in cold beds and late Carrots. In the fourth, we employ the cloches which had been over Cos and Cabbage Lettuces. The trenches are made beforehand. The soil taken from the first trench is carried to the place where the last is to be made. When the trenches are made, the manure is brought and worked as already described, and then covered with a layer of soil. After this the frames are placed, and the first plantation made. The others are treated in the same manner in succession. In this way no time is lost, as the first plants are growing while the work is going on. A trench of the first season should be 4 feet 4 inches wide by 1 foot or 14 inches deep; one of the second season, 3½ feet wide by 10 inches or 12 inches deep; and one of the third, 2½ feet or 2 feet 8 inches wide by 8 inches or 10 inches deep. The same remarks apply to trenches for cloches. Immediately after planting, the cloches should be covered with manure, which is to be removed when the plants have rooted, and air should then be given at once. As the season advances, gentle waterings should be given more frequently. The seeds of the best-formed and finest fruit should be preserved, having been previously dried. In drying, care should be taken not to handle them too much before they are completely dried. The seed keeps good for five years. It is impossible to cultivate the Melon in the open air in the climate of Paris. Very hot seasons may ripen a few fruit without the aid of artificial heat, but these cases are exceptions. In damp cold years, Melons are subject to a disease which manifests itself by the appearance of immense numbers of insects, which, in forty-eight hours destroy all hope of a crop. I. P.

Grapes in Bottles.—I find (says Mr. Tillery, of Welbeck, in the *Florist*) that I can keep ripe Grapes best and longest in bottles of water, by hanging them in a late Vinery, where plenty of ventilation can be given, as well as a little artificial heat in damp cold weather, some shading being likewise required on bright sunny days in April and May. Three years ago, I had a dark room fitted up with shelves to suspend the bottled Grapes on, and, although the room was well ventilated, the Grapes damped, and did not keep so well as in the late Vinery. When they are kept in such a Vinery, the growing Vines in the house begin to get into full foliage by the middle of May, when all the Grapes then left in bottles may be removed and put into a fruit-room, where they will keep the supply up for a few weeks longer, should they be required to do so. To have Muscat Grapes well coloured and finished for late keeping, they ought to be forced in January or the beginning of February, for I find the best ripened bunches always keep the best. No varieties of Grapes require more time for ripening than the Muscat, even where there is a good command of artificial heat; and, to have them very fine, the best time to start them is about Christmas.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Nespras nepolica.—This is not Achras, but Loquat (*Eriobotrya japonica*). At least, that is now being sold in the streets under the above name. *FRUITER.* [The paragraph was communicated, we did not see the fruit.—Ed.]

Wiring Garden Walls.—Your correspondent Mr. Grieve, of Calford Gardens, in his quiet unobtrusive way, approving of the communication of "One who Practically Knows," appears in favourable contrast last week to Mr. Baines, of Southgate, on this subject. Like Mr. Grieve, I am desirous, however, to learn the results of fair and unprejudiced trials of the new French system of wiring walls. Mr. Baines has certainly not yet given one single valid argument against it.—FAIR PLAY.

Origin of the Green Gage Plum.—The origin of the name, says *Notes and Queries*, is simply that the Plum was brought into England about the middle of the last century, by the Rev. John Gage, who was in some way connected with a monastery or conventional establishment in France. He lived much abroad, but frequently visited his brother at Hengrave Hall, near Coldham, in Suffolk. In one of these visits he brought over from the garden of the monastery grafts of this excellent fruit tree, which were cultivated in the garden at Hengrave Hall, and soon were spread throughout England.

A HOLIDAY TOUR.

BY THE EDITOR.

(Conclusion.)

Of Italian Gardens Generally.

As Italian gardens have very much influenced the gardens of other countries, and, for the most part, unfavourably, it may not be amiss to say something here of their origin and character. As to their origin, a glance at almost any part of Italy explains that. The Romans did not make terraces, because they admired them for their own sakes, but because the nature of the ground absolutely required them. For purposes of cultivation the hills are terraced in many parts like stepped stairs. The Italians did not build so that there was "a hill behind."

To shelter their devotion from the wind.

To avoid the malaria of the valleys and for purposes of defence, the towns crest the hills as the head of the young Mushroom does its stalk. When gardens were made in such positions, terraces to support the soil and form level walks were as necessary as earth and water. At Rome, where the immediate environs, unlike those of Naples, Genoa, and many other cities, are not hilly, the fashionable resorts, such as Tivoli and Frascati, were of a character to necessitate the terrace also; what was needed in most cases became the mode everywhere; the rude stone wall of the cultivator supporting a narrow slip of soil for his Olive trees or Vines became, in the ornamental garden of the wealthy Roman, an architectural feature, varied by vases, statues, &c. As regards the essential elements of Italian gardens, they are simple, and there is no need to go to Italy to understand them. The spirit of their design we have in many geometrical gardens in England; their sources of beauty, we have in England, too, everywhere the Cypress or the Pine flourishes, it is mainly owing to a few coniferous and evergreen trees, notably the Cypress and the Stone Pine, and, in a lesser degree, to Agaves, Prickly Pears, and Palms. In the exact ratio, in which these prevail over and veil the architectural and other artificial features, are the gardens beautiful. In the abundance of its vegetation we find the source of the charm of the Pamphili Gardens at Rome, a garden which is well shown in our page illustration. The sparseness of the vegetation explains the stony and distressing aspect of not a few gardens laid out in this style at home and abroad. It is, however, only just, as we find it illustrated in Italy, to say that there, as a rule, vegetation is more paramount than in many gardens in other countries. Elsewhere it is not unusual to see the terrace bare of anything beyond a few low shrubs and bedding plants; while, as to placing imposing plants at frequent intervals on the walls, as in the Pamphili Gardens, it is never thought of with us. It is essential to bear in mind that the beauty of an Italian or geometrical garden of any kind will depend on the predominance of vegetation over the merely artificial. This may be said to be true of all gardens, and so it is, no doubt; but it applies to the Italian more than to any other, inasmuch as it is in that style in which artificial features predominate most. Italian gardens, allowing of an endless variety of architectural work, apart from that of the house, they have naturally been much in favour with architects and artists, who have taken up the profession of landscape-gardener. The landscape-gardener proper, so to say, impressed by orthodox custom, and not attempting to think for himself, chimes in with the popular notion that every house, in no matter what position, should be fortified by terraces, and is busy forming terrace gardens, usually on level ground, which is unsuitable for them. Hence it comes that vast sums, ostensibly devoted to gardening, are spent on water-works, fountains, vases, statues, balustrades, walls, and stucco work. By the extensive use of such materials many a noble lawn is cut up; and, sometimes, as at Witley Court, the architectural gardening is pushed so far into the park as absolutely to curtail and injure the prospect—that is, if the prospect of a noble well-wooded park or arborescence is better than that of a posing-ground for the objects above enumerated. Many of the houses before which we see these formidable arrays would themselves seem to require much further embellishment from the hand of the artist architect. Indeed, if the east of the stone and stucco ornament lavished on

THE PANIHILI GARDENS AT HONOLULU.

the garden, in many cases, were spent on its legitimate object—the house, it could not fail to be a change for the better, for architecture as well as gardening. The fact is, the style is only worthy of serious adoption with us when the ground favours it, as, to name an English example, at Shrubland. There it is used, with a very pleasing effect, to lead from the house down a steep bank to the pleasure-grounds below. Nothing can be more pernicious for gardens than the too popular notion that the right plan is to place an Italian garden on the best front of the house, no matter what the nature of the ground; the fact being, where the ground is level, a finer effect results from allowing the turf to roll up to the walk in front of the house than from an elaborate terrace, as may be seen on the north side of Holland House, and at Cambridge House, and in such Gardens as Oak Lodge, where there is a very narrow terrace. There is, of course, in many cases, need for a formal walk, raised or otherwise, and, it may be, for a small terrace—points which will be governed in each case by the position, and by the house itself in various cases; but, where the ground, as in most English gardens, is level, there is no occasion for more. Such a foreground leaves us free to adopt everywhere a purely artistic and natural style of gardening. The needlessness of terrace-gardens in every position we have long shown in *THE GARDEN*; and so good a landscape gardener as Mr. M'Nab, of the Royal Botanic Gardens, Edinburgh, has recently declared his opinion to the same effect. In level town gardens, where the excuse of formal surroundings is used to justify a stony style, it is also a mistake. The highest effect is to be obtained, not by carrying numerous architectural details into the usually small town or city garden, but, by securing an absolute contrast between the garden vegetation and its unavoidable formal surroundings. And this end should be secured in such cases, not by aiming at the sham picturesque with rocks, cascades, and undulations of the ground, which would be too obviously artificial in such a case, but mainly by the simple majesty of trees and the charm of level turf. Thus it has been affirmed that none but an Italian garden would have suited South Kensington. Well, we had an elaborate garden designed there, and skilfully designed in its way. The plan was carried out with the greatest care; the planting, &c., was done by experienced gardeners, yet the result, as everybody knows, was unsatisfactory in the highest degree. There are many private gardens in European cities, of a more limited extent and with more formal surroundings, which are beautiful in the highest sense, and as devoid of the aspects that offend many in such a garden as Kensington, as if they were in some happy valley far away from the city. One feature of Italian gardens deserving of especial comment is the statuary. It is important, even with us, who are never likely to possess such a plethora of it as Italy. There, what it is capable of doing for gardens may be judged of everywhere, even unimportant palace gardens having frequently scores of statues and busts. Notwithstanding the wealth of art thus bestowed, it is rare, indeed, that a good effect is seen. On the contrary, the result is often spotty and objectionable, as in the Pincio, at Rome, where there is quite a regiment of new busts; and at Caserta, where the clipped masses have statues laid against them at regular intervals. In the distance, that is to say, in the landscape, such spotting about of statues and busts is exceedingly offensive, because it prevents the vegetation from expressing itself, so to speak. At a distance of a few hundred yards or feet, the varied forms and hues of a variety of trees and shrubs may be full of attraction, but a line of statues or busts and pedestals ranged along its face, as not unfrequently occurs in Italy, neutralises the effect of the vegetation. Then, again, in a real garden, there are, or there ought to be, many living objects to attract the attention which a number of statues or other artificial objects may distract. In the very multitude of statues and busts in an Italian garden, there is weariness. One or two fine works, isolated near some mass or grove of evergreens, might be introduced happily—the more so if the statue had any associations connecting them with the place; but it is doubtful if it would not be better to have such works under cover. No one who witnesses the disfigurement and decay of statues in the open air, here and elsewhere, can doubt, that, for mere safety's sake,

all works of any value from an artistic point of view should be under cover. If the works are of no such merit, it is not wise to so place them that they continually interfere with the pleasant impressions one receives in a fair garden. And if these things be true of the green tree what shall we say of the dry? How is it when Venus is leprous with Lichen, when Mars is armless, and when the lion has lost his tail? In Italy, in the open air, statuary is distinguished mainly by mouldiness. It is not only the moist climates of the north and west that favour the small spreading growths which so disfigure the forms wrought in marble. Everywhere in Italy, from Genoa to Caserta, the statues that have been more than a year or two in the open air are half-covered with a dirty blackish mould-like Lichen, which adheres to them as closely as if it grew with the marble itself. The result is grotesque effects in nearly every garden where statues or busts are seen; the expression of the face is distorted, or the form itself robbed of its expression, from half of its surface being obscured by an offensive blackish Lichen. If this would only grow equally over the whole surface, the statues might be mistaken for those of a curious hybrid race, with Greek and Roman heads on negro bodies. But it persists in growing in great flakes, now throwing a mantle over one side of Apollo, and now bestowing on Psyche one blackish cheek and a discoloured nose. All these facts being considered, it will probably be admitted that marble statues are best under cover; and that, in any case, a garden is not the place for them. Another error worth noting is that of placing large groups of sculpture in central positions, in gardens such as those shown in the illustration of the Doria Gardens at Genoa. In the engraving (see p. 379) the artist has, by the introduction of touches which suggest the grace of vegetation, managed to produce a pleasing effect, whereas the actual effect is miserably poor—at least to anyone who seeks for natural beauty in a garden. In this case, all the objections urged against statues hold good; but here they are more offensive, inasmuch as they occupy the best positions, and frequently destroy the precious quality known as “repose” in landscape-gardening.

THE GARDEN IN THE HOUSE.

WINDOW GARDENING IN SPRING.

My windows, being south-east, catch the morning sun, which I consider most fortunate, for my garden never looks better than in the early morning, just after sunrise; and I may as well add, that most of my window gardening is done between five and seven o'clock in the morning, since my employment calls me out from seven a.m. until five p.m.; yet that does not detract much from the pleasure I obtain from my plants; indeed, I often think that working men derive more real enjoyment from the cultivation of a few common flowers than professional horticulturists, who are continually brought in contact with the choicest exotics. Before relating my gardening operations, I will give an account of the cost of boxes, seeds, roots, and other appliances. This information is as much to be desired as cultural experiences, yet we rarely see it given in horticultural papers.

COST OF APPLIANCES.				£	s.	d.
2 Window-boxes, @ 3s. 6d. each	0	7	0
4 Brackets, for safely fixing same, @ 4d. each	0	1	4
1 Bushel of soil	0	1	6
50 Crocus bulbs (mixed)	0	1	6
12 Hyacinths	0	2	0
12 Narcissus	0	1	6
12 Packets of mixed flower seeds	0	1	6
12 Flower-pots	0	1	6
Miscellaneous plants	0	5	0
Water-can	0	1	6
6 Hyacinth glasses, @ 4d. each	0	2	0

£1 6 4

The above may seem to be a large sum at first sight to spend on the embellishment of the sitting-room windows, but a little consideration will show it to be otherwise. Before I commenced, I went to the florists and inquired the price of common wooden window boxes, and found that I could not get these

under eighteenpence or two shillings per foot run, so I at once determined to get a jobbing carpenter to make mine to order. I soon found an industrious man who offered to make them for 3s. 6d. each, of well-seasoned deal, $\frac{3}{4}$ -inch stuff, and the whole well painted (two coats) inside and out. Now, my boxes will last me at least five years, and, probably, much longer, as they will not have to be removed, so that the annual cost amounts to a mere trifle. To have bought these at the shops would have cost me at least double what I paid for them, and the chances are they would not have been so useful and substantial, although rather better finished. The pots and water-can will last for years with care, while many of my plants are of permanent interest; so, that if we reckon the average cost of my little garden for five years, the annual expense will not be nearly so much as it would appear from the account given above. And now a word or two about my plants. The first plant that bloomed with me was *Eranthis hyemalis*, which opened its yellow flowers and unfolded its bright green foliage early in February. This is a very common plant, that grows abundantly in many shrubbery borders, but it is never seen to better advantage than when planted in a pot or window-box so that it is near the eye of the observer, for, when seen by the thousand in borders outside, it always seems to me to have a weedy appearance. After the *Eranthis* came Crocuses, both purple, yellow, and white, and these made my boxes gay for a month at least, or until the middle of March, at which time the Hyacinths commenced to bloom. The varieties of the latter were all single kinds; half of them I grew in water and the others in pots, and as far as my own experience goes, the latter did much the best, and produced by far the finest heads of flowers. Of those grown in glasses, two rotted away entirely, and I attribute this to my having allowed too much of the bulb to dip into the water; the other four did produce a few flowers, but nothing worth mention. For the future I shall grow all my Hyacinths in pots of rich sandy earth in the same way as the nurserymen and florists who grow for market. I have just now a fine show of *Narcissus*, great clusters of pure paper-white flowers, with deep orange cups, and their foliage is of a very delicate bluish wax-like green colour quite distinct from anything else I grow; these have been much admired by everyone in the neighbourhood. Along with these I have two plants of the common orange-flowered Wallflower, a couple of dwarf purple Iris, which are blooming very freely, but their richly-tinted flowers do not last well. A young and healthy Virginian Creeper in a pot at one of the windows is just putting out its green foliage from its delicate pink shoots, and, I have no doubt, this will form a striking feature in my arrangements for the summer and autumn. One of the freshest of all my Creepers is, however, a plant of German Ivy, which I hear is much used in America, but not as yet common in this country. This grows very quickly, and bears very bright shining leaves, something like those of the common Ivy in form, but of a much more pleasing green tint. My other plants consist of *Echeverias*, *Mammillarias*, and *Sempervivums*, and, as central plants for little stands in front of each window, I have an India-rubber plant on one side and a fresh feathery *Acacia* on the other. These are both green and healthy, and form very interesting objects, that I would not be without on any account, as the former was a present and the latter a seedling raised four years ago, and it gets more beautiful every season, and is always attractive. I purchased two tufts of Creeping Jenny, a week or two ago, and these have grown amazingly and will form nice fresh little plants; I intend to suspend them from wires, so that their leafy shoots can hang down gracefully all round the pot sides. My plants are all healthy, and I attribute this to their being frequently sprinkled overhead and occasionally sponged with clean soft water to clear them of the fine dust that so soon accumulates on house plants in the smoky town. In addition to the above, I have a plant of common Ivy in one of the boxes, and this is growing freely, so I shall train it over a hoop so as to form a graceful arch over the box. In pots, I have seedlings of Ten-week Stocks, *Asters*, *Convolvulus major*, *C. minor*, *Nemophila insignis*, *Mignonette*, and Canary Creeper. These are coming on nicely, and as soon as the *Narcissus*, Wallflowers, and Iris, have done blooming, I shall empty out my boxes and fill them again. W.

PLANTS SUITABLE FOR TABLE DECORATIONS.

In all countries and ages flowers appear to have been intimately associated with the customs and ceremonies of mankind. They have been adopted as the emblems or badges of nations and races—as the Rose of England, and the Lily, or Flower de Lys, of France—and the Red and the White Roses of the rival houses of York and Lancaster, are in the recollection of everybody; and flowers of various kinds have, from time immemorial, found a welcome in the palaces of the rich and the cottages of the poor. It has long been the custom to place vases or glasses of cut flowers upon the dinner-table, and it has, also, of late years, become the fashion to associate with these flowers, growing plants of various sorts; but all, of course, adapted to this purpose on account of the beauty of their flowers or their foliage, the pots, too, in which such plants are growing are generally concealed by some skilful device when placed upon the table, or they are placed in vases of china, silver, or similar material; and, on this account, it is desirable to have plants intended to be used for this purpose, growing in comparatively small pots. The classes of plants suited to the purpose are, of course, various, comprising varieties hardy as well as tender; but, as a rule, plants with ornamental foliage, and berry-bearing plants, are generally to be preferred; not that there can be any objections to the use of flowering plants for this purpose, but, as such plants are generally associated, when placed upon the table, more or less, with vases or glasses of cut-flowers, which will generally sufficiently represent the floral element, while the ornamental foliage, or the fruit of growing plants, constitutes a pleasing variety. The heated atmosphere of the apartment is, moreover, not unlikely to cause some delicate-flowering plants to drop their blooms, even before the close of the first evening of their doing duty in such positions. The following notes only apply to a few varieties of table plants, most of which have been found to be well suited for this purpose, and in all cases it will be understood that it is necessary that the plants should, in most instances, be growing in pots not exceeding 6 inches in diameter.

Several of the Bromeliads prove useful plants for table decorations, such as the *Æchmea fulgens*, when it has thrown up its graceful spike of coral-like flowers; then it is a very suitable object to place upon the dinner-table, and, when about to be used for that purpose, it should be held in an inverted position for a short time, in order to allow the water which may be lodged in the axils of the leaves to run out. It is easily increased by means of suckers, which are produced around the neck of the plants, when they are about to flower; these should be cut off, and potted singly into 3-inch pots, and placed in a stove temperature, where they will soon root, and should afterwards be shifted into larger pots when required. Young and well-formed plants of the *Bonapartea juncea* also form graceful objects for table decorations, as do also the *Beaucarnea glauca* and *recurvata*. They are by no means particular as to soil, and will generally succeed well in a compost of moderately rich turfy loam and peat. Many of the Palms and Cycads, when in a young state, form elegant and appropriate objects for the centres of dinner-tables; and a selection of the most suitable sorts should be kept growing in 6-inch pots for that purpose. They can be propagated from suckers or truncheons produced upon the stems of old plants, or they may be raised from seeds, and will succeed in any moderately rich light soil. Succulent plants, although generally somewhat grotesque in appearance, may, nevertheless, be occasionally used for table-decorations, more particularly when associated with cut-flowers and flowering plants of other species; they may consist of well-formed plants of such species as *Pachyphytum bracteosum*, *Rochea falcata*, *Echeveria metallica*, *Sempervivum arboreum*, as well as of grafted specimens of *Epiphyllum truncatum* and its varieties, when in bloom. But, when plants in the form of standards are used for this purpose, it is desirable that the stems should be of sufficient length to elevate the heads of the plants, so as not to obstruct the view across the table.

Many Ferns are exceedingly well suited for table decoration, particularly the *Adiantums*, or Maiden-hair Ferns; among the most beautiful of which is *A. Farleyense*. The *Athyrium Filix-fœmina*, or Lady Fern, is a hardy and beautiful variety, well suited to this purpose; as is also the *Cheil-*

anthes elegans, together with *Gymnogramma chrysophylla* and *Massonii* among the golden sorts; and *G. calomelanes*, *tartarea*, and *Peruviana argyrophylla* among silver varieties. The *Lomaria gibba*, *Neottopteris australasica*, and *Nidus*, the Bird's-nest Ferns, young plants of all of which make very suitable objects for table decoration; as does also the *Nephrolepis exaltata*, and many of the tree varieties in a young condition. These are all increased by means of seeds, or by division. Some of the *Begonias* are also suitable plants for table decoration, although the majority of the ornamental-foliaged section is too spreading in habit for the purpose. A very beautiful dark-foliaged upright-growing kind, named *B. subpeltata erecta multiflora*, is, however, an exception, as are all the *Boliviensis* or tuberous-rooted sorts; and they may all be freely increased by cuttings put in during early spring. They will succeed in a soil consisting of turfy loam and peat, with the addition of a portion of silver-sand, and require to be grown in a stove or warm greenhouse. The delicately-beautiful foliage of the *Caladium argyrites* renders this plant also suitable for table decoration; although, on account of its dwarf habit of growth, it may not be well adapted for a central position. The bulbs should be started early in March in 3-inch pots, which, when well filled with roots, should be shifted into pots some 5 or 6 inches in diameter. The soil used should be turfy loam, peat, and leaf-mould, with a portion of silver-sand; and, like all the *Caladiums*, it requires a stove temperature. Nearly all the varieties of *Croton* may likewise be made useful for table decoration; and, on this account, it is advisable to strike a few plants of each sort from cuttings every season, which may be inserted either in autumn or early in spring. The soil they require is a mixture of peat, loam, and silver-sand; and they require a stove temperature. Probably, the best varieties for the purpose are *angustifolium* and *variegatum*. *Coleus Verschaffeltii*, and its congeners, make excellent table ornaments. They are all of easy culture, but in order to bring out the brilliant tints of their exceedingly ornamental foliage to the greatest advantage, it is necessary to grow them in a stove temperature, although they will all succeed tolerably well in a warm greenhouse. They are by no means particular as to soil, but a suitable compost for them may be formed of loam, leaf-mould, or well-rotted manure, with a little sand. In order to have plants of the desirable size, it is necessary to strike a few plants from cuttings several times during the season, and they will generally be found to naturally assume the pyramidal form, which is that most desirable for plants required for table ornaments; and this can also be induced, or assisted, if necessary, by judicious pinching. *Cyperus alternifolius variegatus* is a very elegant and suitable plant for table decoration, its paper-white leaf-stalks and striped foliage having a very remarkable and pleasing effect. It is easily increased by division, and the only difficulty regarding its culture is that of preventing the production of green leaves.

The genus *Dracæna* furnishes many plants whose brilliant-coloured foliage and graceful habit render them all that can be desired for table decoration, and they will generally succeed well when grown in soil consisting principally of turfy loam, with a portion of peat, leaf-mould, and sand. They may, also, be rapidly increased by means of cuttings, or eyes; as the tops of over tall specimens may be cut off and potted in sandy soil, in 3 or 4-inch pots, and placed under a hand-glass in a stove, where they will root in a fortnight or three weeks. Large plants, too, cut down to nearly the surface of the soil will soon produce several young shoots, that can be formed into cuttings, which soon take root, and the stems of plants so cut down may be split down the centre, when each division, cut into pieces of about an inch in length, containing an eye, or undeveloped bud, will strike if gently pressed into pots or seed-pans filled with a compost formed of sifted leaf-soil and sand plunged in a mild bottom-heat, and covered with a hand-glass. Some few of the species will succeed in a greenhouse temperature, but the sorts best adapted to table ornament, such as *D. Cooperii*, *rubra*, *terminalis*, *gracilis*, and others, require a stove.

Among ornamental-fruited or berry-bearing plants the most useful for table decoration are the various varieties of *Solanum Capsicastrum*, which naturally form themselves into compact bushy or pyramidal plants of about a foot or 18 inches in

height, and, when properly managed, bear a profusion of shining orange-coloured berries, or bright crimson cherry-like fruits, which last in perfection during many months. These *Solanums* may either be raised from seed sown in March, or they may be propagated by means of cuttings inserted about the same time; when fairly rooted they should be potted singly and grown in a genial temperature until about the end of May or beginning of June, when they should be planted out in a warm situation, fully exposed to the sun, where they will flower freely, and, if well attended to with water, should the weather prove dry, they will be sure to set abundance of fruit. The plants should be carefully lifted and potted in moderately rich light soil, in pots some 6 inches in diameter, during the early part of September, when they should be placed for a short time under a wall, or in some similar position, so as to be sheltered from the mid-day sun. They should, also, be frequently sprinkled with water, until they are fairly established in their pots, and in due time they should be placed on a shelf near the glass in the greenhouse, where the fruit will soon become finely coloured, and the plants will altogether be found to be exceedingly ornamental throughout the entire winter. If it be desired to keep the plants for another season in order to have fine large specimens, they should be cut in, or pruned back, about the end of April, and planted out, as before directed, about the end of the following May, and again re-potted in September in pots proportioned to their increased dimensions. Healthy well-formed young plants of the *Ardisia crenulata*, when well furnished with scarlet fruit, are also suitable as table plants during winter; they are of easy culture and require a stove temperature; as does also *Rivina humilis*, which, when clothed with its long pendulous racemes of bright scarlet berries, likewise forms an interesting object upon the dinner-table.

Skimmia japonica (a dwarf hardy berry-bearing shrub, of slow growth) is also very suitable for table ornaments, when kept in pots, as are likewise many of the ornamental fruited *Capsicums*, bearing, as they generally do, an abundant crop of highly-polished fruit, of a bright yellow or scarlet colour. They are all half-hardy annuals, and require to be sown in a hot-bed during March.

Among that class of plants known as tender annuals, some of the *Amaranthuses* and *Celosias*, especially the latter, are exceedingly useful for table decoration during the autumn and winter months. They must all be raised from seed, which should be sown in a hot-bed about the middle or end of March. They require a rich light soil, and when fairly established in 6-inch pots, they may be successfully grown in a warm greenhouse temperature. Among the best varieties are *Celosia pyramidalis*; *C. plumosa aurantiaca*, a kind which produces large terminal plume-like racemes of rich chrome-yellow flowers, *C. aurantiaca nana*, a variety with fine orange-coloured feathery plumes; *C. plumosa ignea*, with fine crimson plumes; and *C. Huttonii*, a very ornamental dark-foliaged sort.

Among hardy herbaceous plants, which may be found useful for table decoration are the graceful *Dielytra spectabilis*, and its white-flowered variety, neatly formed flowering plants of which, established in 6-inch pots, are found to be exceedingly effective; as are also plants in bloom of the *Hoteia* or *Spiræa japonica*, more particularly its variegated form, viz., *S. japonica aureo-variegata*, which forms one of the most decorative and graceful of table plants. Its fine glossy ornamental foliage is traced throughout with bright gold-coloured veins, while its snowy-white erect feathery flowers are produced in great abundance. It is equally as hardy as its green-leaved congener, and will thrive in almost any soil, but in dry seasons it should be abundantly supplied with water; it is easily increased by division.

It has already been said that when plants in pots are placed upon the dinner-table the pots should, if possible, be concealed in some way. An ingenious contrivance, recently introduced, named the "Postulata," effects this desideratum perfectly. It is formed of strong cardboard, of various sizes and in different styles, elegantly ornamented. It also contains a concealed zinc pan, which effectually prevents the transmission of damp or moisture to the tables, and all so contrived as to be readily folded up and put away when not in use.

P. GRAYE.

Culford, Bury St. Edmunds.

THE ARBORETUM.

ORNAMENTAL PLANTING.

By CHRISTOPHER YOUNG MICHIE, Callen House.

THERE is no branch of forestry which so much demands sound judgment, refined taste, and correct ideas, as that which treats of landscape or ornamental planting. It is not enough that we can admire and appreciate a well-defined and harmoniously coloured landscape, or be able to judge correctly of its merits or defects. Our province as planters is to select the materials, and so dispose and arrange them as to produce an effect at once the most powerful, agreeable, and perfect, that they are capable of doing. To attain this end—the proper arrangement and distribution of trees in a demesne or landscape—the planter requires an amount of skill and knowledge only attainable by perseverance, investigation, and study. To plant with any degree of certainty as to future results,

crooked, twisted and contorted, become pendent and drooping at the extremities; its leaves also become darker in colour. At that season of the year, when Nature, stripped of her leafy honours, has sunk into repose, and the eye is fatigued with gazing on the dull and naked landscape, joyous relief is afforded by the glossy green of the Scotch Pine, which, in winter, is arrayed in richest emerald. In sheltered situations it attains the height of 100 feet, grows to an immense size, and survives several centuries. The Silver Fir (*Picea pectinata*), on account of its hardness and accommodating qualities, is entitled to a conspicuous place in the landscape. Its form does not much change with years, being the same in its mature growth as when a young tree, namely of a pyramidal or conical form. There is an irregularity and stiffness in its appearance, which renders it a conspicuous object when viewed among the other trees of the forest, generally towering from 10 to 20 feet above the highest in cold and exposed districts. It retains at all seasons a deep olive-green, its leaves underneath having white streaks, which, when upturned by

Central group in the Doria Gardens, Genoa (see page 376).

it is necessary to know not only the history, nature, and habits of every tree planted as correctly as the artist does the colours he uses, but also the properties and peculiarities of the various soils in which he plants, the aspects and position of the ground to be planted, the effects of the elements at every season of the year, as they act upon the plant in its various parts, more especially the buds, foliage, and fruit. As introductory to our subject, we shall at first indicate and describe some of the leading peculiarities and characteristics of our common forest trees, after which we shall the better know how and where to dispose of them to the greatest possible effect in the landscape. The Scotch Pine (*Pinus sylvestris*), is pre-eminently the tree of the mountain; it is never so much at home or so suitably placed as when it crowns the mountain-ridge, clothes the precipitous hill, adorns the projecting cliff or hoary rock, or guards the rugged pass at the entrance of a Highland loch. No tree in the forest undergoes so great a change in form and colour as the Scotch Pine. When young, its shape is conical, and its leaves of a lightish green; when aged, its top spreads out—its lofty branches,

the wind, present a shining silvery appearance—whence the name. It requires a pure clean soil, with moisture, and free exposure. It attains an immense height, with proportionate girth of stem, and survives 200 years. The Larch (*Larix*) is esteemed more for its utility and profit than its beauty in the landscape. Its principal merits in the latter respect are its sweet fragrance in early summer, its soft green appearance, contrasted with other trees at its early period of foliage, its often pendulous form vying with the Birch in gracefulness, and the beauty it so quickly imparts to the landscape after being planted, not to speak of its adaptation to the climate and soil. It attains the age of 200 years, and becomes a very large tree. The Spruce (*Abies*) has all the disadvantages of the Larch in point of beauty, while it is destitute of its merits. In any part of the landscape where Spruce would grow, other and superior trees might be substituted. There are, however, certain places, such as soft meadow ground, where the Spruce, at least for the sake of variety, may very properly be planted. Its recommendation for such situations are, endurance of frost when once a few feet high,

and tendency to absorb moisture from the ground, and ameliorate the climate. By the latter means its period of existence is greatly protracted, although its existence seldom exceeds 150 years. The Oak (*Quercus*) is a general favourite, seldom regarded as either out of place or keeping with the general landscape. The highest praises have been bestowed upon the Oak in all ages. It has been called "monarch of the wood," "king of the forest." It is probably the greatest favourite of all our hard-wood trees, being alike esteemed when a sapling as when a centenarian. Apart from poetical or historical associations, the Oak is deservedly a most interesting as well as valuable tree. It survives several centuries, attains over 100 feet in height, throws out magnificent wide-spreading branches, and contains occasionally 1,000 cubic feet of timber. The Beech (*Fagus*) is a noble tree, and well adapted to a great variety of situations, provided only the soil be moderately dry. The colour of its foliage changes considerably during the year, being of a very light green at first, which gradually becomes darker as the season advances, till the autumn tints appear, when its beauty still seems to improve, and it finally assumes a warm russet-brown or orange colour. It attains an immense size, and survives several centuries. One variety of the Beech, *Fagus purpurea* (the purple-coloured), merits an important place in the landscape. Though generally considered deficient in size as compared with the common Beech, yet, on account of its rare, rich, dark, glossy foliage, it is singularly desirable. It attains a good size, and survives to a considerable age. The Sycamore (*Acer Pseudo-Platanus*) when all its merits are justly weighed, stands in the first-class of forest trees. It is well adapted to stand either as a single tree upon the lawn, or to form groups in other situations. Its foliage being darker than that of most other deciduous forest trees, and its leaves large and rich in texture, it is a great favourite near the mansion. In autumn, the foliage generally retains its dark olive colour, when it suddenly changes, although upon southern exposures it sometimes changes into a light olive, but seldom assumes a high-toned colour. Its trunk attains an immense size, frequently 30 feet in girth, while its far-spreading arms describe a wide circle, supporting leaf-covered branches, which rise in cloudy masses one above the other to a great height. It also survives to a long age. The English Elm (*Ulmus campestris*) bears in its outline a striking contrast to many other trees, being of considerable upright habit of growth. Upon good dry loam and in a sheltered situation, it attains to a large size, and survives to a considerable age. The Scotch Elm (*Ulmus montana*) has many recommendations as a landscape tree, whether viewed standing alone, forming avenues, or in groups. It is a bold-spreading tree, of great size, and attains a great age, provided the soil be dry and rather rich, with an open loose sub-soil. The Norway Maple (*Acer platanoides*) possesses rare qualities as an ornamental tree. Its appearance upon the lawn is imposing, its beauty of foliage equally charming, whether viewed close at hand or seen at a distance. It is equally pleasing at all seasons. In summer, its fully-expanded leaves are most beautiful; in autumn, its colours, red, brown, orange, and yellow, impart to it a gorgeous lustre; in winter, too, when snow is on the ground, the buds and newly-formed twigs, which are of bright red, show to good advantage. Its scaly trunk resembles more a column of stone than wood; and whether supporting a canopy of green or golden foliage or leafless branches, is an interesting object in the landscape. The Ash (*Fraxinus*) whether as regards its form or the freshness of its emerald green is a noble and beautiful object. Its massive fluted or cylindrical trunk, its swelling majestic arms and pendent branches, together with its broad expansive top, render the Ash a first-class tree; while its long soft Grass-like foliage pre-eminently qualifies it for select spots in the landscape, such as the central part of a large group of dark-foliaged trees where the surface of the ground forms a concavity, or the lower part of a wide glen; in either situation it is an appropriate and lovely object, imparting during summer a beauty to the sylvan scene such as no other tree can, except the Walnut. Its size is immense; age, from 100 to 200 years. The Lime (*Tilia*) possesses many qualities to recommend it as an ornamental or landscape tree—its magnificent fluted trunk, wide-sweeping limbs, dense cloudy top, so rich in summer foliage, and the sweet fragrance of its flowers, so attractive of myriads of honey-gatherers busily humming around it. In forming avenues, shady walks, and covered drives, no tree is so suitable as the Lime. In the south of England or elsewhere, there are carriage drives of considerable length entirely overshadowed by magnificent canopies of Lime, appearing like immense arcades supported on rows of magnificent sylvan columns. It attains a large size, and survives to an old age. The Horse Chestnut (*Esculus Hippocastanum*) is of exquisite symmetry, and one of the loveliest trees in the wood; it is adorned with great beauty of foliage and flower. Its tender massive foliage is, however, easily injured by severe weather, and its wood being soft and brittle, is not suited for

an exposed situation. In a sheltered spot, however, with a moderately good and dry soil, it becomes a large and handsome tree, but, unless under very favourable circumstances, does not remain handsome or attain a great age. The Sweet Chestnut (*Castanea vesca*) well deserves a place in the landscape, both on account of its symmetry and beauty of foliage, flowers, and fruit. It becomes a large tree, and survives, under favourable circumstances, to an old age. Owing, however, to its tendency to become ring-shaken, which deteriorates much the value of its wood, and shortens its existence, it is often preferable to plant Elm in its stead. The wild Cherry (*Cerasus sylvestris*) is suitable for many parts of the sylvan landscape. It thrives under extremes of climate and in any soil, but does not well sustain the rigour of the sea breezes. It is also desirable on account of its profusion of white blossom in spring, rich foliage in summer, and variegated shades in autumn. In favourable situations it becomes a tolerably large tree, and often attains a great age. The Willow (*Salix*) is well entitled to a place in the landscape, where its graceful slender form presents a pleasing object to view. The situation to which it is best adapted is by the margin of a lake or river side, where it harmonises well with the wave or ripple of the water. The Huntingdon and Bedford Willows are the best for effect in the landscape; the former being of a light green, appearing, in connection with other trees, as if nearly white, demands special attention in point of arrangement, seeing that the contrast is so striking, it is equally liable to mar as to improve the effect. When planting Willows, it should be observed to plant them a few feet above the water-table, otherwise the roots suffer, and consequently the top dies at an early age, hence the necessity for pruning. The Aspen Poplar (*Populus tremula*) is highly commendable as an ornamental or landscape tree. Its outline in the mature state is handsome and beautiful. Its summer foliage is profusely rich and sweet, and even musical or poetical in the gush of sound among its tremulous leaves—ever moving, never at rest, now greatly agitated, now vibrating gently, ever whispering sweet sounds to the sighing breezes. In suitable dry soil, though poor, it attains a fair size, and survives many years; although upon rich soil it attains a large size, it does not live longer. The Lombardy Poplar (*Populus fastigiata*) is a tree desirable for the landscape, more on account of its tall peculiar spiry habit of growth, rendering it a conspicuous and picturesque object, than on account of its beauty. It is nowhere more suitable than in the neighbourhood of a town or country village, where it produces much the same effect as architectural embellishments. As the roots strike deep into the soil, it can only be planted with advantage where the soil is deep and moderately dry. The roots readily decay when surrounded with stagnant water, and hence the trees sometimes are overturned by a storm, not without danger and occasionally accident. The foregoing list of trees comprises those chiefly esteemed by the writer as the most important for forming a first-class landscape. In point of healthy growth, size, adaptation to soil and climate, symmetry, beauty, and general appearance, they are the best, and when properly distributed in a landscape they possess a pleasing variety in respect of shade and colour. Differing from those who affirm that certain trees are void of beauty, we regard every tree as possessing beauties of its own. One tree, however, is admired for one property, another for another, hence the necessity for planting them in natural situations, where they may harmonise with each other and with the landscape in general. For example, a Willow on a dry mountain top, and a Scotch Fir on a fertile river bank, could never please a cultivated and refined taste. In making the foregoing selection, a view has been had to the character of the country where they are planted—bold, hardy, majestic trees for more mountainous districts, and lofty, graceful, slender ones for the more level and sheltered grounds. Where two varieties have stood in competition, as with the Poplars, preference has been given to those possessing the greatest number of good qualities.

Let us now describe a landscape planted with a select number of the trees mentioned in the preceding list, viz., those suitable for an upland district, having an altitude of 1,000 feet to 1,500 feet above the sea, and exposed on all sides, soil poor and barren, sub-soil gravel or rock. Assuming that the mansion is situated in a central part of the estate, near the base of a hill, with a level fertile plain stretching in front. The mansion in such a case is the principal object in the landscape; all the surroundings should harmonise with it. Thus trees of the most symmetrical form and beauty should be artfully arranged nearest the mansion; but, although artfully arranged, art should be so concealed that they should still appear as of natural growth. In the mansion, art should be displayed, in the woods it should be concealed. The highest and most distant part of the landscape may be clothed exclusively with Scotch Pine, for the following reasons: first, on account of the upland soil being better adapted to grow this, and bring it to perfection, than any other tree;

second, because the top of the hill being the most distant part of the landscape, and forming, as it were, the background of the picture, should be planted with Pines of the darkest hue, in order to impart the impression of vastness and extent. About two-thirds of the distance from the summit of the hill to the front of the woodland should be planted with Pine; there the soil becomes better, and the situation more sheltered. A rich herbage clothes the ground, which now assumes a gentle slope instead of the extreme steepness of the mountain top, all which shows that a different class of trees is now required, and suggests, as successor to the Pine, the Birch, also a native of the mountain, and a tree which naturally harmonises and associates with the former. Viewed in connection with the Scotch Pine, the Birch is soft, rich, and warm. It imparts a beauty to the summer landscape, while in autumn it assumes a golden tinge, which gradually deepens into orange, yellow, or red, until the whole has the same array of gay and gorgeous drapery. The manner in which Birch and Pine should be planted, so that their varied foliage may be intermingled, can best and only be decided by the natural surface of the ground. Where it undulates, the Birch extends and occupies the hollow ground; the Pines occupy the higher ridges, and should rarely appear lower down upon the hill in detachments; a detached portion of Birch may appear, however, in a ravine amongst the Pines. In either case great nicety is required in mixing the two sorts, so that their marginal lines may blend softly together. The Birch has recommendations for such a situation because of its certainty to thrive, become a fair sized tree, and survive to considerable age. The Aspen Poplar should succeed the Birch, and join with it in the same manner as described for the Birch with the Pine—the Birch occupying the lower ground, and the Aspen the ridges and more elevated parts. The reason for this is, that while the latter is equally hardy with the former, and thrives in as poor a soil as the Birch, its branches are bolder, somewhat resembling the Ash or Oak, its top lofty, broad, and cloudy, while its foliage is richer and brighter. Thus it is superior to the Birch for a prominent and conspicuous situation; further, its foliage bears exposure better than any other deciduous tree in the forest, being found fresh and uninjured by high winds, when even the Birch, growing by its side, has sustained much injury; and not only are its leaves beautifully formed and of a rich colour at all seasons, but the slightest breath of air elicits from them streams of sweetest music. Besides these advantages, it well befits the landscape of an upland district, from its deep-toned golden hue in autumn. To complete the background of the landscape, we have now to indicate the trees suitable for the base of the hill and around the mansion. It is important to select a variety of trees fitted to adorn this situation. Trees of large size, with healthy, rich foliage, and such as attain old age, bold and noble in outline, pleasant in summer, gorgeous in autumn, and beautiful at all seasons, are those which are required. The Beech has many of these qualities, and is well suited for such a situation as that under consideration. The warm tints of its autumnal foliage, and pleasing colour at all seasons, constitute important merits of the Beech as a landscape tree, to which may be added its noble spreading branches, gigantic cylindrical trunk, lofty spreading top, and majestic appearance. The background, or part behind the mansion, on the exposed side, is finished by introducing a few groups of other trees, as suggested by the nature of the soil or diversity of the surface, such as the Wild Cherry, Common Ash, or Scotch Elm. Our next consideration is, what trees should stand singly in the park and around the lawn, forming the foreground of the picture, the altitude being 1,000 feet above the sea, and at such a height, inland, and beyond the influence of the sea air? The following we should recommend:—the Sycamore, as being hardy, of noble appearance and luxuriant foliage, shady in summer, and ornamental in winter:—the Oak, its merits being hardiness, noble growth, large size, beauty of foliage, and great age:—the Scotch Elm, with noble spreading top, sweep of branches, rich foliage, large size, old age:—the Beech, as alike suitable for the parks for forming a background; its merits have been already noticed. The common Ash is a notable headed tree of great size. It grows upon poor soil, is beautiful in summer, and picturesque in winter.

Having described the arrangement of trees in a landscape at as high an altitude as trees grow properly in Scotland, we shall now consider what is required for a landscape in a fertile part of the country, with a situation variously sheltered and exposed, altitude from 300 to 600 feet. In this case, unlike the preceding one, a great variety of first-class trees can appropriately be introduced, on account of the better quality of soil, greater diversity of surface, and lower altitude. Taking our stand point of observation to the south-west front of the well-known Floors Castle, in Roxburghshire, where an extensive district appears before us stretching far in the distance, comprising an area of many miles, comprehending almost every variety of soil, and with great diversity of surface, we shall give an arrangement of trees suited to such a district. Assuming that the

whole surface of the district is destitute of trees, and that it is resolved to plant so as to cover the ground with the noblest trees the soil is capable of sustaining and bringing to perfection, and in such an arrangement as to gratify the taste, and please the eye, beginning with the background, which rises in the distance to a height of, say 600 feet, this we would plant with Scotch Pine, as being darkest in colour, and having a gloomy aspect in the distance. Its great size, bold and rugged appearance, also recommend it for such a situation. A second hill, less elevated than the former, and which stands in the same line, but at considerable distance towards the foreground, we would plant with Sycamore, on account of its large spreading top, dark massive foliage, and the old age which it attains, together with its other merits as a landscape tree. The next elevated ground in the same line as the two preceding hills, but a little less elevated and reaching still nearer the foreground, we would plant with Norway Maple, for the following reasons:—First, on account of its importance as a magnificent timber tree, picturesque and romantic appearance, and the great age it attains; second, on account of its light showy green appearance in relief against the darker heavier foliage of the Sycamore, which only changes its colour before dropping off on the first approach of winter. Towards the front of the last mentioned knoll, the ground generally inclines for some distance. The sloping ground we would plant with Oak, for the following reasons:—For its magnificence and its unequalled majesty. Its trunk, limbs, branch and foliage are all magnificent. Its autumnal effect is less striking than that of the Maple behind it; but, at the same time, it is more diversified. In a healthy Maple plantation, the colour of the autumnal leaves is nearly uniform, viewing the whole surface, while that of the Oak greatly differs, even in the branches of a single tree. The Maple, therefore, forms a fitting contrast and suitable background to the Oak. Having described the background, which consists of four successive ridges or zones, one rising above the other as they recede in the distance, we turn next to the left hand view, as seen from the castle. This is an extensive plain, sloping gently, and of a more uniform surface. The most distinct view here is only about half that of the preceding one. To begin with the most distant view, and upon which the sun shines in early morning, we would plant this with Sycamore, for the following reasons:—On account of the general merits of the tree, which we have already described; in consideration of its heavy dark foliage floating on the top of the hill, or descending its slope. The Sycamore being dark, heavy, and ponderous in outline, conveys not only an impression of weight and importance, but also of distance. Next to the Sycamore should succeed Beech, the former forming a background to the latter, not only suitable in summer, but equally so in autumn, retaining as it does, its dense dark foliage, while the Beech in front of it has changed into a warm russet brown. The loose airy irregularity of the Beech, too, contrasts well with the Sycamore, which is stiff, round, and cloudy in outline. Next to the Beech should follow the Lime tree, which has a close compact outline, widely differing from the Beech in summer, while late in autumn it maintains its summer greenness till the leaves suddenly fall off. In this position, the Lime forms an excellent contrast with the preceding and succeeding zones or belts of trees. In front of the Lime we would again plant Norway Maple. The former being darker in foliage than the latter, forms to it a proper background. In autumn, too, while the Lime is yet green, the Maple is of a bright shining yellow, or orange colour. Assuming that we have now reached nearly the base of the hill, and come upon level ground, and that a terraced appearance can no longer be produced, Art must accomplish what Nature further denies. We would, now that we have reached the base of the hill, introduce a zone of common Ash. First, on account of its partial obscurity when stripped of its leaves in early autumn, or when yet naked late in the spring; second, in consideration of its soft, long, grass-green foliage during summer, which no tree in the forest, save the Walnut, equally possesses. For the base of the hill, the bottom of a glen, or centre of a concavity, no tree is so well adapted. The Ash should be planted in a narrow irregular belt, its extreme margin mixing gradually with the Maple in the background. The English Elm we would next plant, on account of its towering height, which only admits of a partially concealed view of the Ash, and its foliage, which remains unchanged in colour for a considerable time after the Ash has shed its leaves. Next we would interpose a zone of Scotch Elm. It is less spiry, not so tall, more spreading, and altogether softer in outline than the English Elm. In autumn, upon dry ground, freely exposed, the Scotch Elm assumes bright shades, though not of a warm tint. In front of the Elm we would plant Oak, which forms an excellent foreground, and contrasts well with the Elm, thus the general favourite is again brought prominently into view. The whole of this latter arrangement has been made with a view rather to produce contrast and variety, both in form of trees and colour of foliage, than for the purpose of harmoniously blending shade with shade. The latter object is, with the present limited

knowledge of the laws of vegetation, beyond the power of man to accomplish satisfactorily, owing to the foliage changing so much at various stages of growth, and being influenced by their state of health and vigour of growth.

The next view of the landscape is upon the right, taking it from the front of the mansion, as previously. In the distance, the ruins of an ancient castle are assumed resembling that lately erected on Minto Crags, situated upon a peak in the skyline. (If it has historical associations so much the better.) In connection with this relic of warfare, we would plant the extreme height with Silver Firs. The reasons for doing so are because of the hardness of the tree to endure exposure; even the strongest sea breeze affects it less than any other evergreen with which the winter is acquainted. Also, because a skyline studded with Silver Firs has at all times and seasons of the year, when viewed with a hazy atmosphere, a little after dawn, or during the murky twilight, a strange and awe-inspiring appearance, especially if in the vicinity of a fortress or other building susceptible of awakening such emotions. The extreme top of the hill, only at the top of the ravine, is planted with Silver Firs, the part of the hill both behind and in front of the "Silvers" being planted with Scotch Pines, which gradually mix with the former. The castle is embosomed in a mass of Pine, against which it shows in grand relief; its Moss-grown weather-beaten walls show to a great advantage against the dark foliage of the Pine. No Silvers are planted close upon the castle, as this would render the outline of the building too complex and undefined. Next to the Scotch Pine, with advantage, might be introduced a zone of Aspen Poplars, taking care not to mix the trees where the two classes join, but to carry a distinct but irregular line between them, so that the Pine may appear to come down abruptly upon and overhang the Aspen. Upon this, in a great measure, depends the effect of the landscape. We would next introduce a zone of Sycamore. This is intended as a background to the succeeding belt, and to form a rising cloudy mass representing an elevation in the ground, though none naturally exists. Care and skill are necessary herein the blending of the margins of the different classes of trees. The recommendations of the Sycamore for such situations are its magnificence, both in respect of trunk and top, its dark, shady foliage in summer, and slight tinge of greenish-yellow in autumn. The next zone is Beech, which forms an excellent contrast to the Sycamore behind it. In outline, being more loose and airy, its summer foliage of a lighter and softer green, and in autumn of a brilliant colour, it shows conspicuously against the dull background of the Sycamore. The next zone is Lime, which is of a stiffer outline than the Beech, of a dull green in summer, and in autumn changing but slightly. It forms an excellent contrast with several other trees, especially the Norway Maple which succeeds and forms the next zone. The merits of the Norway Maple as a landscape tree having already been described, need not here be repeated, except to remind the planter of its beautiful summer green and incomparable rich yellow in autumn. It, therefore, gives a striking effect with the Lime forming its background. The next zone is English Elm, which, from its towering character and different colour, both in summer and autumn, forms an excellent contrast to the Norway Maple, which should rise in a high mass behind it. The next and last succeeding zone is Oak, of whose merits nothing need further be stated beyond what has already been done. This again brings us to the foreground.—*Transactions of the Scottish Arboricultural Society.*

CLADRASTIS LUTEA.

This forms a tree which grows from 20 to 30 feet in height and bears a profusion of pure white flowers in July or August. The flowers are arranged in elegant drooping panicles, and contrast forcibly with the finely-cut pinnate foliage. Its thin

seed-pods, though rarely seen in this country, are borne on short stalks. It is frequently known as *Virgilia lutea* or *V. tinctoria*, the latter being perhaps the name under which it is best known in gardens and nurseries. When covered with its panicles of snowy flowers, it forms a noble ornament on lawns or in pleasure-grounds. It requires a dry warm soil and a sunny situation—conditions under which the wood becomes thoroughly well ripened, and the flowers are more freely produced the following year. It is also very effective in autumn, as its foliage assumes a brilliant golden tint previous to its falling off. Planted near a Purple Beech it would be very effective. It is a native of N. America. ARBOR.

THE LIBRARY.

CONTRIBUTIONS TO THE FLORA OF MENTONE.*

THOUGH late in reviewing this volume, we, nevertheless, feel bound to do so, as it is of peculiar interest from a horticultural point of view. The district to which it relates is one of the richest in Europe as regards its winter flora. When, in spring, the fields and copses of the more southern Italy are only whitened by the Daisy and the Sloe, many of the beautiful flowers of the Riviera have passed out of bloom. This arises from the peculiarly favourable position of the country. All the district is favourable to vegetation, but Mentone may be described as situated at the "foot of a south wall." The Alps come down here to sun themselves by the sea, and, in doing so, keep away the bitter winds of the north and east. Hence we find the Lemon thriving better than in South Italy; the *Wigandia* in superb bloom in the gardens in spring, and the Castor-oil plant living well through the winter. The Olive is not here the poor over-worked and over-pruned thing it looks in many parts of Italy, but always a fine and picturesque tree, and often a stately one; and, beneath the Olives and Lemons, on those Myrtle and Rosemary-clad headlands that run into the many-hued sea, and on the hills above the Vine and Wheat terraces, and on the crags and Alps behind them and in the mountain valleys and high pastures, grow the many flowers, the most interesting and rare amongst which are figured and described in Mr. Moggridge's book. Among these are not a few plants well worthy of culture for their beauty, as, for example, the scarlet *Anemone fulgens*; *Lavatera maritima*, with its delicately tinted flowers; *Pæonia peregrina*; the beautiful *Primulas Allioni* and *latifolia*; *Crocus medius*, a fine kind; *Leucojum hyemale*; *Campanula macrorrhiza*, *Allium neapolitanum*, as valuable as any Daffodil; many kinds of *Ophrys*; *Cytisus Ardoini*; *Potentilla Saxifraga*, a handsome dwarf species whose pure white petals are prettily relieved by a central tuft of crimson anthers; *Leucojum nicaense*, a graceful little plant peculiar to this district, with smaller flowers, and more slender leaves than those of the common Snowdrop; *Globularia alypum*, a rare plant, with exquisitely beautiful blue flowers; the singular-looking *Fritillaria montana*; five species of *Serapias*; not to name other equally beautiful plants better known in our gardens. These, and many other plants, are well figured by Mr. Moggridge himself, and his book forms a collection of plates of much interest to horticulturists, as well as to the many who resort to the fair climate of Mentone in winter and spring. It is an illustrated local flora of the highest merit, and such a one as may form a model for other districts, possessing botanical wealth and an intelligent population to take an interest in it.

* "Contributions to the Flora of Mentone, and to a Winter Flora of the Riviera." By J. Traherne Moggridge, F.L.S. London: Lovell, Reeve & Co.

Cladrastis lutea.

WORK FOR THE WEEK.

The Flower Garden.

ALTHOUGH our springs of late years have rendered early bedding-out undesirable, it is not too early to decide how the garden shall be planted, and to make arrangements accordingly. What may be termed the massing system has had its day, and it is evident that something fresh must soon be introduced. We would have masses of colour in suitable situations, but we would have them subdued and tastefully toned down by means of foliage, so as to form a rich, quiet, and harmonious whole. Even ribbons, if a mere repetition of the same plant *ad infinitum*, cease to charm; and the same holds good in the case of panelling and carpet-bedding, where gaudy colours are employed. The secret of gardening decoration does not consist in crowding hundreds or thousands of plants, however scarce or valuable, into a given space. No; it lies more in the judicious use of appropriate plants, and in so lighting them up by means of colour, that each shall enhance the beauty of the other. For this purpose expensive materials are unnecessary; it is the arrangement rather than the plants individually which charms. One man with a handful of flowers from the hedgerow will often produce an exquisite bouquet; while another, with flowers however choice, might fail. Tasteful application of the material which may be at command is what is wanted. Spring-flowering plants, although now doing good service, will soon require to be removed to the reserve garden, the ground in which should be put in order to receive them; add to it a little thoroughly-decomposed manure, leaf-soil, or peat, as the case may be. Before re-planting, divide into small portions such plants as Aubrietias, Arabis, and Daisies, &c., allowing sufficient space between the plants for proper development, without crowding. Bulbs must be removed in as perfect a manner as possible, being careful not to bruise the leaves in the operation, and on no account remove the flower-stems, as they greatly assist the maturation of the roots. Water freely, and protect from sunshine for a few days with evergreen branches. Plant out spring-struck Hollyhocks, and divide and re-plant Neapolitan and late-flowering Violets. Centaureas should be plunged in the beds in pots, as they grow more compactly, colour better, and are more manageable in winter. Clip Box-edgings, and everywhere maintain perfect neatness and order.

Greenhouse.

In order to prolong the flowering season of such plants as are in bloom under glass, it will now be necessary to attend carefully to shading during the middle of the day in sunny weather. Scrim, a fabric made of flax, is much the best and cheapest shading material in the end. The finest quality of it will break the sun's rays without excluding too much light. Roof climbers will now require regular attention to keep them from becoming an entangled mass. The system of allowing the whole roof to become covered, as is frequently done, is objectionable. It excludes too much light from the plants underneath, especially in dull weather; it also spoils the general effect, which is much enhanced by confining climbers to something like one-fourth of the roof space, and leaving them to hang down gracefully at intervals; yet in this too much uniformity should be avoided, by allowing some to hang lower than others. Let every means be employed to keep them free from insects, more especially scale. Azaleas that are brought into bloom in other structures for removal to the greenhouse or conservatory, will be benefited by sprinklings overhead with the syringe every afternoon until their flowers are fully expanded; they should also be shaded, especially the high-coloured varieties. They must, likewise, be well attended to with water, as, during the development of their flowers, there is a much greater drain upon the roots than at any other time, and if allowed to become dry the flowers suffer as well as the growth for the ensuing year. Geraniums and Calceolarias that are throwing up flower-trusses should be encouraged by means of liquid-manure, not too strong, especially in the case of Geraniums, or it causes them to run too much to leaf. Fumigate regularly, and not too severely. Fuchsias stake, stop, and tie. Closely examine them to see that they do not suffer from aphides or red spider, as either quickly spoils them. Cockscombs, Balsams, Achimenes, and Hydrangeas should be well attended to, as these, with the plants previously mentioned, will be the principal things to be depended on during the following two months, when there is a much greater scarcity of flowering-plants than during early spring. Chrysanthemums that have filled the small pots they at present occupy, should be at once potted into their flowering-pots; from 8 to 12-inch pots, according to the sizes the plants are required, will be found large enough for general use. If fine flowers are wanted, stop the shoots during this month, but not later. A dozen really good blooms on a plant of the large-flowered varieties are preferable to three times the number of starvelings often met with. Plunge them at once in their summer quarters in shades, which will prevent worms from getting into the pots, and will

keep their roots at a much more equable temperature than when not plunged. The effect of rapid change in the temperature of the soil in an ordinary plant-pot when not plunged is not sufficiently considered; during bright weather the effect of the sun's rays acting upon the pot raises the earth heat in an unnatural degree, and therefore the cold chill of even our summer nights causes a corresponding reaction. The first batch of Primulas and Cinerarias will now require potting into thumb-pots, using good loam, well enriched with rotten dung and leaf-mould, for the purpose, mixed with a little clean sand; place the plants in a somewhat close pit or frame; shade them from bright sun, and attend to them well with water. Pot off all cuttings struck of Euphorbias, Hydrangeas, and Poinsettias, placing them in a growing temperature near the glass, so as to ensure short stout growth. *Rhynchospermum jasminoides* is a useful conservatory plant, its fragrant white flowers rendering it a general favourite. It is a plant of easy management, requiring the temperature of a Vinery, or intermediate house, during its growing season. The different varieties of *Kalosanthes* will now be fast showing flower, and will be benefited by weak manure-water. Get them properly tied before the shoots get too heavy. They are useful decorative plants for summer. Now is a good time to propagate them; they strike freely in loam or peat, with an admixture of a little sand, giving very little water until they are rooted. Tie out *Achimenes*, as they advance in growth, giving them all the light possible, so as to induce a stout blooming habit. A good number of the oldest plants of scarlet and pink Geraniums should be selected for keeping up the conservatory display during the summer and autumn; and a batch of the scarlet *Pelargonium Vesuvius* should be potted into 6-inch pots and turned out of doors, where they will be fully exposed during the summer to the full sun. With these it is not size that is required; but a thoroughly matured growth, that will ensure their flowering freely when subjected to heat for winter decoration.

Fern House.

Plants that have not been re-potted for some time, and where it is not deemed advisable to give them more root room, may be assisted by the application of manure-water; but, in all cases, see that the drainage is effective, otherwise its application will only aggravate the evil. If any plants are out-growing their bounds, either in pots or planted out, it is an easy matter to reduce this over-luxuriance by cutting away, more or less, according to circumstances, their oldest fronds whilst in a green lying state; this will be found to reduce the size of the fronds made afterwards, in proportion to the extent it has been carried out. The different kinds of *Dicksonia*, *Lomaria*, *Cyathea*, &c., that throw up their young fronds in a batch may have, when these are fully developed, the oldest fronds, if unsightly, cut away.

Hard-wooded Plants.

Azaleas will now be coming into flower without the assistance of fire heat, and although with the increased temperature of the season they will not last in bloom so long as those that have been forced, yet the much brighter colours which they acquire under more natural conditions will compensate for their shorter duration. The house they occupy whilst in bloom should be well shaded, in order to prolong their flowering as long as possible. Remove all seed pods from such as have done flowering; after which allow them a fortnight or three weeks to recruit their energies previous to re-potting. Use in the operation good fibrous peat broken into pieces proportionate to the size of the plants; add nothing except as much silver-sand as will not only ensure porosity; but also maintain a sweet healthy condition of the soil for years; for Azaleas, with anything like fair treatment, are not short livers. After potting keep them in a closer atmosphere than they have been in for a few weeks, and shade during bright sunny weather. Admit no side air during such time, but give sufficient at top to keep the temperature from getting too high; 80° or 85° with air, shade and moisture will do no harm; on the contrary, Azaleas enjoy it. Plants that are vigorous and that push some of their shoots very strong will be benefited by having the points of such shoots nipped out, as soon as they show a disposition to outgrow their neighbours; if done whilst the growth is soft the plants will push several shoots, which will set blooms with the rest of the plant. Attend as heretofore to the general stock of hard-wooded plants, and by close attention encourage early and vigorous growth.

Indoor Fruit Department.

Pines should receive plenty of water and heat, the fruit being neatly tied to stakes, and where size is required, all suckers, as they appear, may be removed. Keep the atmosphere rather drier than ordinary for Grapes that are colouring. Thinning, stopping, and tying of Vine shoots must be attended to, and inside borders should be particularly guarded against getting too dry. Give abundance of water to Figs that are swelling. Peaches that are past the stoning

period should be thinned to the required distances apart. Ripening Strawberries should be kept somewhat dry; those that are swelling require a little manure-water, and pass the hand gently over those that are in flower, in order to assist fertilisation. As soon as the soil of the Melon beds is filled with roots, they should be top-dressed, packing the soil firmly, and placing over it an inch of loose mould. Overcrowding shoots or foliage should be prevented, and single flowers not allowed to set; on the contrary, all should be removed until a fair crop can be set at once. Cucumbers must not be permitted to bear too heavy a crop at one time; thinning and surfacing, as for Melons, should be carried into effect, except that the compost used should not be so firmly packed, and should be of a richer and more open character than that used for Melons. Sow Vegetable Marrows, and transplant those that are ready. Continue to pot and harden off Tomatoes.

Hardy Fruit and Kitchen Garden Department.

In cases where the disbudding of Peach, Nectarine, and Apricot trees has commenced, protection from frosts cannot yet be dispensed with, and great care should be exercised to guard against strong sunshine in the mornings after frost, as much damage is sometimes done by brisk sunshine at that time. As a protection against the attacks of green fly, the trees should be frequently syringed with tobacco-water. Double-bearing Raspberries should be cut down to within a few inches of the ground, to encourage autumn fruitfulness. Asparagus beds, for the present, should have all their produce cut, *i.e.*, none should be allowed to run up, except, perhaps, here and there a stem or two for seed. Full sowings must now be made of Salsafy, Scorzonera, and Skirret, in lines a foot apart. A few seeds of White Dutch, and of Red and White Stone Turnips should now be sown. Sow round-leaved Spinach between lines of Peas and in open spaces amongst other crops; also, a late crop of Carrots in deeply-worked sandy loam, not too rich. Celery plants should be pricked out and freely exposed. Sow Peas for succession; those up should have a little earth drawn up to them, and be staked; the latter practice also applies to Beans. Sow the main crop of Beet and French Beans in warm situations. Cauliflower, for late cropping, should be pricked out, and Cabbages, of which another small sowing should also be made.

THE KITCHEN GARDEN.

EARLY AND LATE PEAS.

THE number of varieties of early and late Peas now in seedsmen's lists is so great, that it is puzzling to know how to make a selection. The following sorts were grown and proved by me last year; and I can recommend them as being the best, either for large growers, or for amateurs with only a limited space for their cultivation. In the earliest section, the Ringleader, or First Crop, is still the first fit for use; followed by Sangster's No. 1, Taber's Perfection, Emerald Gem, and Kentish Invicta; but the earliness of some of these varieties does not compensate for their small pods, lack of flavour, and poor cropping qualities. Some, however, prefer their flavour to the richer Marrow flavour of the following early new sorts—namely, Laxton's William the First, Alpha; and, in the older dwarf Marrows, Little Gem and Multum in Parvo. If sown at the same time as Ringleader, all these sorts are only a very few days after that variety in coming in for use, and have far larger pods and better flavour. For forcing early in pots, both Little Gem and Multum in Parvo are exceedingly well adapted; and I have had them ready for gathering in the beginning of May in some low pits built on purpose for growing early vegetables. Maclean's Blue Peter is a new dwarf variety, and is likewise said to be very early and prolific for growing in pots. In the second-early section, Maclean's Advancer is a wrinkled Marrow of excellent flavour, and an abundant cropper. Laxton's Fillbasket, Quality, and Maclean's Best of All are likewise very excellent Peas, with a Marrow flavour. For the general crop, G. F. Wilson is also one of the very best new Peas lately sent out, both for flavour and productiveness. Laxton's Superlative is everything described about it as regards its large pods; but they fill very unevenly, and the Peas are not of first-rate flavour; yet it is worthy of growing as a show sort. The old favourites, Veitch's Perfection and Ne Plus Ultra, are standard varieties for late sowing, and will keep the supply up till the frost in autumn cuts them down. Where accommodation can be found for very tall-growing kinds, Williams's

Emperor of the Marrows is a very productive late sort, of the British Queen section. Magnum Bonum, another new tall late kind, is highly recommended as the largest and best flavoured Pea grown; and Laxton's Omega as the very latest that can be grown. To cultivate late Peas successfully on dry soils, they should be sown in drills which have been prepared as for Celery trenches, namely, with plenty of rotten manure dug into the bottom of them, to at least 18 inches deep. The Peas ought to be sown 6 inches lower than the surface of the ground, to allow for earthing them up, and to retain the waterings which must be given them in dry warm autumns, or the mildew will appear, and soon render the crop unproductive.

WILLIAM TILLERY.

HISTORICAL NOTES ON VEGETABLES.

Maize or Indian Corn (*Zea Mays*) now so widely spread over the South of Europe, does not appear to have been introduced from America till nearly a century after the discovery of that Continent, though mentioned as a valuable article of trade in the West Indies by several travellers of the sixteenth century; it is shown to have been still unknown in Spain at the close of that period, and it was not until after the year 1610 that it found its way through Spain and Sicily into Italy. Professor Targioni-Tozzetti satisfactorily shows that all supposed mention of this grain by earlier writers before the discovery of America referred to other kinds of grain, though under some of the names since given to the Maize.

Rice was, in the year 1400, still only known in Italy as an article of import from the East. Its cultivation was introduced into Piedmont and Lombardy in the end of the fifteenth or commencement of the sixteenth century, either directly from India by the Portuguese, or through Spain and Naples by the Spaniards. Some of the varieties now grown in India appear to be but little removed from their wild prototype.

The Sugar-Cane is merely alluded to because its cultivation was attempted in Tuscany in the sixteenth century, but found totally unsuited to the climate. Of Asiatic origin, while the wild type is not uncommon, it was carried to the West Indies, and thence introduced into Sicily in the time of the Saracens. It was also, perhaps, for a short time, cultivated in Calabria, a point which has been much disputed, although of no importance, as no success attended the experiment if made.

Leguminous Plants.—The cultivation of these dates from a period of very remote antiquity, for Professor Targioni finds them mentioned by nearly all the ancient Greek and Latin writers on Georgics, and their origin is difficult to trace.

Haricots or French Beans.—These came from the East Indies, where the kinds are said to be numerous. The species, however, are not nearly so numerous as is generally supposed; thus, the *Phaseolus vulgaris* includes at least eight of the commonly adopted species of modern botanists, the *P. lunatus* four, the *P. Max* or Mungo (which is either dwarf or climbing, like the *P. vulgaris*) five or six, the *P. Truxillensis* three or four, *Dolichos* (or rather *Vigna*) *sinensis* four or five, *Lablab vulgaris* at least as many, *Canavalia gladiata* two or three, and so on. This multiplication of species has not been owing entirely to the considering as botanical species what are mere varieties of cultivation, but in several instances it has arisen from the same varieties having been received from Asia, Africa, and America, and separately described without adverting to their common origin.

The Common Bean (*Vicia Faba*) has been vainly sought for in a wild state. The vague indication of supposed habitats in Persia, or on the shores of the Caspian, have not been confirmed by modern researches. May it not, however, had its origin in the *Vicia narboensis*? a species not uncommon in the Mediterranean region from Spain to the Caucasus, and very much resembling the Bean in every respect, except in the thinness of the pod and the smallness of the seeds.

The Tomato.—This, if ever found wild in the Eastern Archipelago, has only spread from cultivation, for it is now ascertained to be exclusively of Peruvian origin, and was not known in Europe until after the discovery of America. It appears, however, to have preceded the more useful Maize and Potato, for Matthioli mentions its introduction in his days, that is, in the commencement of the sixteenth century. It was first cultivated rather for ornament than for food, which may, perhaps, explain its more rapid introduction.

The Capsicum.—There is great uncertainty as to the real native country of the Capsicum or Hot-pepper (*Capsicum annum*, Peperoni of the Italians, Piment of the French), now so universally spread over all tropical countries. Although long known under the name of Indian Pepper, it appears not to be indigenous in Asia, and

there is no authentic record of its cultivation in Europe before the discovery of America. It is said to be really wild in that Continent, and Cæsalpin and Clusius, late in the sixteenth century, both speak of it as introduced from thence. Yet, in the time of Matthioli, early in the same century, and, consequently, at a period when very few of the natural productions of the New World had been transplanted to the Old, we find, at least, three varieties well-established and abundantly cultivated in Italy, under the name of Indian Pepper, which is hardly probable if it had been really introduced from America, then so recently discovered. A curious instance of the slowness with which the use of culinary vegetables is spread, is afforded by the large green mild variety of Capsicum, which is so much eaten over a great part of Spain and some of the adjoining French departments. It was carried by the Spaniards into Naples during their dominion in the sixteenth and seventeenth centuries, and has ever since remained in common use there, without spreading further. It makes an excellent salad, having all the flavour of the Capsicum without the slightest pungency.

The Sweet Potato or Batata (*Ipomœa Batatas* or *Batatas edulis*).—This is one of those maritime plants which are spread over the shores of both the New and the Old World, within or near the tropics, but its cultivation appears to have originated with the Americans. It was, evidently, unknown to the ancients, and the first mention of it on record, is by Pigafetta, who found it used as an article of food in Brazil, where he landed in 1519. Its first introduction into Europe was, probably, by Oviedo, after whose return to Spain, in 1526, it was cultivated at Malaga, and from thence sent out to different parts of Europe.

Lettuces, Chicory, and Endive, appear all to have been in cultivation ever since the time of the ancient Greeks and Romans, without any record of their first introduction. The numerous varieties of the Lettuce have been referred by modern botanists to three supposed species (*Lactuca sativa*, *L. capitata*, and *L. crispa*), and, as no plants so characterised are now to be found wild in our own quarter of the globe, their origin is vaguely assigned, as usual, to East India. That country may, however, be well ransacked before Cabbage or Cos Lettuces are met with growing wild in the mountains. Their prototypes may be sought for, with much better chance of success, amongst the common wild *Lactucæ* of the Mediterranean region, but can only be determined with any degree of probability by a more correct knowledge of the changes produced by luxuriant cultivation on their foliage than we now possess. The cultivated Chicory is universally acknowledged to be but a slightly altered variety of the wild plant (*Cichorium Intybus*) so common over a great part of Europe; the Endive, on the contrary, is always enumerated as a distinct species (*Cichorium Endivia*) of unknown origin, unless it be "East India." We fear it must share the fate of the Lettuces, be erased from the list of botanical species, and reduced to the rank of a cultivated variety of the Chicory.

Professor Targioni's researches convince him that the **Carrot** and **Parsnip** were both known to, and cultivated by, the ancient Greeks and Romans; but that, until the middle ages, as far as can be traced from the vague descriptions of early writers, the Parsnip was very much more general than the Carrot, although, since then, the proportions have been everywhere reversed. The Carrot, indeed, appears much more susceptible of improvement under the enlightened cultivation of modern days, and the readers of our "Horticultural Transactions" will recollect, in the second volume of the second series, a paper of Vilmorin-Andrieux's, in which he gives an account of the manner in which he succeeded, in the course of a very few years, in converting the thin, wiry, useless white roots of the wild Carrot into a crop of fine, well-shaped, rich-coloured roots, equal to our best garden varieties.

The **Finocchio**, so highly prized by the Italians, especially in the southern portion of the peninsula, is comparatively a modern vegetable. It has, however, produced several marked races or permanent varieties, amongst which the principal are the *Finocchio forte*, but little removed from the common Wild Fennel, the *Finocchio dolce* or Sweet Fennel, and the *Finocchio di Bologna* or *Finocchione*, with the lower part of the stem (or head) much enlarged and succulent. These three varieties are considered by modern Italian botanists as so many distinct species, the two last stated to be of unknown, but probably of "Grecian or Syrian," origin. But Professor Targioni admits that they are not mentioned by any Greek writers, and that the *Finocchio di Bologna* was a new vegetable brought to Florence from Bologna in the middle of the sixteenth century. They are surely all cultivated varieties or races of the common Fennel, which is truly wild in most parts of Mediterranean Europe.

Beet.—The cultivated Beets are referred by Italian botanists to two species, of which one only, *Beta Cicla*, is admitted to be of native origin, whilst the true *Beta vulgaris* is stated to be indigenous to Central Asia, Egypt, and the shores of the Mediterranean, to the

exclusion of Italy. Moquin-Tandon has, however, more correctly reunited the whole under the Linnean name of *Beta vulgaris*, of which he reduces the numerous forms to three principal races—First, the Wild Beet, with a slender hard root, sparingly introduced into kitchen-gardens for the foliage, occasionally cooked with sorrel to diminish the acidity of the latter. Second, the White Beet, *poirée* or *poirée-carde* of the French, with a thicker, but still hard root, with enlarged leaves, and a great tendency to succulence in the petioles, which are blanched like Cardoons for culinary purposes. This vegetable is frequently mentioned by ancient Greek and Roman writers. Third, the Beet-root, *barbabietola* of Italian gardens, *betterave* of the French, so well known for its sweet and succulent root, was first introduced into Italy in the sixteenth century, from Germany, where it was probably first produced. A sub-variety of the Beet-root, with a somewhat coarser and larger root, now become so important an article in agriculture, was originally put forward under the name of root of scarcity, *racine de disette* in French, or Mangel Wurzel in German.

Spinach (*Spinacia oleracea*) was unknown to the ancient Greeks and Romans, but appears to have been early used by the Arabs, transferred to their gardens from the plains and lower hills of Western Asia, where it is now found wild. The Moors carried it with them into Spain, from whence it gradually spread, in the middle ages, over the rest of Europe. It has now generally replaced the Orache (*Atriplex hortensis*), a plant also of Eastern origin, but of much earlier introduction, as it appears to have been known to the ancient Greeks under the name of *Atraphaxis*, and to the Romans under that of *Atriplex*.

Asparagus (*A. officinalis*), indigenous to Italy, as well as other parts of Europe, is mentioned both by Cato and Pliny as carefully cultivated, and attaining a considerable thickness in their days, and has ever been a favourite vegetable among the Italians, who grow it to great perfection; they likewise eat the thin, almost thread-like shoots of the wild plant.—*Journal of the Royal Horticultural Society.*

The Colorado Potato Beetle.—Mr. Elliott, of St. Martin's, Stamford, has kindly furnished us with a specimen of the destructive beetle known as the Colorado Potato bug, collected in Illinois last year, the possible introduction of which into Europe has lately been the subject of some anxious speculation. According to M. Carrière, the accounts of this insect, which have lately appeared in several journals, have all erred in referring it to the genus *Doryphora*, from which it is sufficiently distinguished by the absence of the peculiar lance-like sub-sternal projection to which the genus *Doryphora* owes its name. The proper name of the Colorado beetle is *Chrysomela decemlineata*. It is a pretty little brownish beetle, scarcely half an inch long, marked on the back of the wing-cases with ten strong longitudinal black lines. In this respect, and also in the absence of the lance-like projection, the specimen which we have received agrees exactly with the figure given by M. Carrière in the last number of the *Revue Horticole*. The *Doryphora*, which is also figured there, is nearly double the size of the *Chrysomela*, and has the wing-cases marked with numerous black dots instead of lines. Its true name is *D. multipunctata*. The confusion of the two insects appears to have been originally made in the American journals, from which the account was copied into our English papers. The *Chrysomela*, then, would seem to be the true Potato bug, of whose ravages we have heard so much; while the *Doryphora* does not specially confine itself to that plant, but also attacks Tomatoes, Egg plants, Winter Cherry, and, in some parts of Illinois and Wisconsin, has even established itself in Cabbage plantations.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Canadian Wonder Bean for Forcing.—We have never been one day without this Bean since last November. It is certainly the best forcer with which I am acquainted. It excels all others in its cropping qualities. It is, in short, first-rate in every respect, the individual Beans being nearly twice the size of those of other kinds—6 to 8 inches long, straight as gun barrels, tender and delicious.—R. GILBERT.

The Best Tomatoes.—Mr. F. R. Elliott, who has had a good deal of experience, gives the *Rural Home* some of his observations on some of the leading varieties of the Tomato. The early Hubbard is very early, but not profitable for market. The early Smooth Red, when genuine, is the earliest that is profitable. The General Grant closely resembles it. Hathaway's Excelsior is the best Tomato for the main or general crop.

Diseased Cucumbers.—I have a house, 54 feet long and 10 feet wide, filled with Rollisson's Telegraph and Blue Gown Cucumbers. Of these, the first are just coming into full bearing; but, yesterday, when looking at them, I was surprised to find that gum was oozing from their sides, thereby completely spoiling them. Is there any remedy for this disease, or can any of your readers inform me of anything that will check its progress? Do plants inherit it from their parents that have been attacked, or are they individually liable to be attacked?—A CONSTANT READER.

THE FEVER GUM TREE.

(EUCALYPTUS GLOBULUS.)

THE following account of "the properties and uses" of this tree, is taken from a lecture lately delivered to the Royal Botanic Society, by Professor Bentley:—"The first and most important influence which this tree exerts, and that which has brought it more especially into notice, is its power of destroying the malarious agency which is supposed to cause fever in marshy districts; from which circumstance it has been called 'the fever-destroying tree.' It is in this respect commonly regarded as being serviceable in two ways—first, by the far-spreading roots of this gigantic tree acting like a sponge, as it were, and thus pumping up water and draining the ground; and, secondly, by emitting odorous antiseptic emanations from its leaves. Probably the influence of the latter is but small; although I am by no means of the opinion entertained by some writers, that these emanations are without effect. I do not certainly believe, as has been recently stated, that the branches of a solitary Eucalyptus tree can have had any effect in neutralising the malarious influence of a district previously constantly infected by fever; but I do think that the foliage of groves of Eucalyptus trees, by diffusing an agreeable, aromatic, camphoraceous, stimulating odour in the surrounding air, does have an appreciable influence in neutralising marshy miasmas, and thus improving the healthiness of the district. The great influence is, however, in my opinion, unquestionably produced by the power the roots possess of absorbing water from the soil. It is stated that a Eucalyptus tree absorbs as much as ten times its weight of water from the soil; and hence the enormous suction-power of masses of such trees may in some degree be judged of; so that, where thickly planted in marshy places, 'the sub-soil is drained in a little while as though by extensive piping.' That the main influence of Eucalyptus trees is thus due to the absorptive power of the roots is also borne out by the fact that other plants of rapid growth, when planted in marshy districts, have a sensible effect in diminishing their malarious influence. This is notably the case with the Sunflower, which is grown for this purpose to a large extent in the swampy regions of the Punjab and other parts of the world; and the effect has been that districts which were previously remarkable for their insalubrity are now said to be entirely free from miasmatic fever. But whatever be the cause or causes which render a marshy district thus comparatively healthy to what it was before the introduction of the Eucalyptus trees into the neighbourhood, the fact is unquestionable, and is now testified to in various parts of the world. Thus at the Cape, in a very few years, the cultivation of the Eucalyptus has completely changed the climatic condition of the unhealthy parts of that colony; and in Algeria, where it has been tried on a large scale in a district previously noted for its pestilential air and consequent prevalence of fever, not a single case now occurs, although the trees are not more than 9 feet high; and in the neighbourhood of Constantia it is also stated that at another noted fever-spot covered with marsh-water both in winter and summer, in five years the whole district was dried up by 14,000 of these trees, and the inhabitants now enjoy excellent health. In Cuba, again, marsh-diseases are fast disappearing from the unhealthy districts where this tree has been introduced. In the Department of the Var it is also said that a station-house situated at one end of a railway viaduct, so pestilential that the officials could not be kept there longer than a year, is now as healthy as any other place on the line, in consequence of the planting of a few Eucalyptus trees. Numerous other instances might be cited to the same effect as having occurred in France, Spain, Italy, Germany, and other parts of the world; and we cannot doubt, therefore, that although the effects have been to some extent probably exaggerated, the statements are substantially correct, and that this tree does possess a most beneficial effect in neutralising and improving the malarious influence of marshy districts, and that attempts should be therefore made to introduce it into those regions where the climatic influences are favourable for its growth and development. Several of the districts into which it has been so introduced have been already noticed and others suggested, so that it is unnecessary to allude further to it here; but we now proceed to allude briefly to the other properties and uses of this tree and of other species of Eucalyptus. In the first place we may state that the timber of many species of Eucalyptus is of very great value, and is largely used throughout the Australian Colonies. The timber of several species is remarkable for its solidity, hardness, and durability, and from its power of resisting the attacks of insects and the teredo, as also the influence of moisture. Such qualities render it valuable for many useful purposes, as, for instance, railway sleepers and maritime works. Among the products obtainable from Eucalyptus wood we must not forget that of potash, more particularly as this alkali can be obtained without sacrifice of any valuable timber, and from localities not accessible to the wood trade.' The richness in potash of this wood may be estimated from the fact that Baron von Mueller found that the ashes of these trees

'contained a larger proportion of potash than the Elm or Maple, which are the trees most esteemed for that purpose in America. The yield from the latter trees is estimated at 10 per cent. of the ashes, while that from the Eucalyptus is 21 per cent.' The barks of various species are also now used to some extent in paper-making; those of *E. rostrata*, *E. obliqua*, *E. corymbosa*, and *E. gonicalyx* are amongst those so employed. The barks of many species are also used extensively for tanning. They owe this property to the presence of constituents similar to those contained in Oak bark and other substances commonly employed in this country and elsewhere for a like purpose. A number of species of Eucalyptus also exude a very astringent substance, which, from its resemblance to the ordinary medicinal Kino both in appearance and properties, is commonly designated as Eucalyptus or Botany Bay Kino. This substance, which, when it first exudes, trickles like blood down the bark of the trees in a semi-fluid state, ultimately hardens into dark red shining masses, which have a very astringent taste. It is employed for similar medicinal purposes as our official Kino, and also for tanning and dyeing. Another substance, called Eucalyptus or Australian manna, is also yielded by *E. mannifera*, *E. viminalis*, and, probably, by other species. Two varieties of this manna have been distinguished. It occurs in small, rounded, opaque, whitish masses, with an agreeable sweet taste. It has a similar action to the ordinary manna in use in this country, and contains somewhat similar constituents. It exudes abundantly during the summer months through punctures or wounds made in the leaves and young bark. As it exudes it hardens, and drops from the leaves on to the ground in pieces sometimes as large as an almond. Another important produce of the Eucalypti is the essential oil. This oil is stored up in the pellucid glands already referred to as contained in the leaves, and readily observed when these are held up to the light by the semi-transparent appearance they then exhibit. These oils are prepared on a very large scale at Melbourne, and form an important article of commerce with this country and elsewhere. One manufacturer alone produces about 1,000 lbs. of Eucalyptus oils per month. These oils generally have a somewhat camphoraceous smell; but the odour differs in the various species, and the oil obtained from *E. citriodora* has a pleasant citron-like odour. Some of these oils have been employed, as Eucalyptus oleosa, as a solvent for resins in the preparation of varnishes; but they are of far more value for diluting the more delicate essential oils used in perfumery. The oils of *E. amygdalina*, *E. globulus*, and *E. citriodora*, are thus more especially employed. The oil chiefly consists of a substance called by its discoverer, M. Cloez (who made some interesting researches on the essential oil of *E. globulus*), eucalyptol, a liquid body, in chemical characters resembling camphor. Most of these Eucalyptus oils are of a yellowish colour, although some have a bluish tint; by re-distillation the oil may be obtained nearly colourless. From the quantity of oil contained in the leaves, they yield, when burned, a very large proportion of gas; and it is said that one of the towns in the gold-regions was for a long time lighted by gas extracted from this source. The gas thus obtained is stated to produce a very brilliant flame; and as much as 10,000 cubic feet have been obtained from one ton of leaves. But the expense of collecting these leaves in a country where labour is so costly appears to have been a barrier to its employment, except under exceptional circumstances.

"We have now, in conclusion, to allude very briefly to the medicinal properties of the Eucalyptus globulus. The febrifugal properties of the bark and leaves of this plant have been testified to by many practitioners. Probably some of the exaggerated statements that have been made in reference to the efficacy of Eucalyptus bark and leaves in fevers have arisen under the mistaken idea that the bark contained an alkaloid resembling, if not identical with, quinine, the well-known alkaloid of Cinchona-barks. But the experiments of Mr. Broughton, the government chemist of Ootacamund, entirely disprove this; for upon careful examination of the bark and leaves, Mr. Broughton states that neither quinine nor the other alkaloids of Cinchona-bark exist in the plant in any proportion. What properties the plant possesses would appear, therefore, so far as known at present, to be due essentially to the presence of eucalyptol, already noticed as the principal constituent of Eucalyptus oil. From the testimony of numerous medical practitioners in various parts of the world where the plant has been introduced, and from its popular reputation in fevers in Australia and other countries, we can scarcely doubt that it does possess anti-periodic properties, although these are far less important than those of Cinchona-bark. Cigarettes made of Eucalyptus leaves are reputed to be efficacious in bronchial and asthmatic affections, and in other ways; when, therefore, we regard the beauty of the different species of Eucalyptus, and the proved influence of *E. globulus* in improving the pestilential character of marshy districts, the genus must be regarded as one of the most important to man in the vegetable kingdom."

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

MANUFACTORIES MADE PICTURESQUE.

AFTER having visited hundreds of manufactories in the north of England, I can fully corroborate your correspondent's statement (see p. 371) that they are in many cases squalid and unattractive owing to the absence of vegetation. In some cases this is owing to the presence of free acids in the air, more especially in such places as Sheffield, Manchester, Halifax, Leeds, and Bradford, where there are many extensive chemical works engaged in the preparation of dyeing and bleaching material, and near such as these it is useless to plant any kind of vegetation whatever, since even the turf itself has a hard struggle for existence, and is not unfrequently beaten in the attempt. There are many thousands of outlying manufactories, however, around which trees, shrubs, and flowers would grow and flourish with all the luxuriance imaginable, and would not only beautify the exterior of these strongholds of labour, and thus, as has been stated, afford relief to busy workers, wearied at watching the noisy loom or whirling spindle, but modern scientific researches prove that the presence of fresh and vigorous vegetation, aromatic shrubs, and fragrant flowers, would exert a beneficial influence on health by reason of their purifying and deodorising influence. I have but little doubt that, if this subject was brought to the notice of manufacturers, they would adopt some course by which they could carry it out at once; especially as they, as a class, contribute largely towards the furtherance of horticulture, and often possess gardens and collections of choice exotics second to none in the country. In recommending this I should not overlook what has already been done in this direction, and, as a notable example, I may instance the pretty elastic web manufactory belonging to Mr. Turner, at Leicester. This is situated at the western extremity of that quaint old town, near the Bow Bridge on the Soar, over which King Richard III. rode on the morning of the battle of Bosworth, and over which his dead body was brought back at night. The factory itself is a conspicuous building, partly surrounded by a neatly kept lawn planted with choice shrubs, Conifers, and tufts of well-developed Pampas Grass, the latter being specially attractive in autumn. The manager's house, a pretty little Gothic building, which was formerly occupied by the proprietor himself, is nicely draped with climbers; while at the entrance gates is a pretty little lodge surrounded by flowers, and graceful creeping plants and shrubs. A few years ago, one of the finest collections of Orchids in this country was grown close under the walls of this factory; indeed, if I mistake not, the surplus steam from the boilers supplied the heat for it; and, on my first visit to the establishment, I was struck by the vigorous appearance of the plants, although some of them trembled at every revolution of the engines; it is, however, not often that one finds the most beautiful of Orchids so near the whirl and bustle of an extensive manufactory. These Orchids are now removed, but the general features of the place are little altered on that account. Some manufactories I have seen in Derbyshire and Yorkshire are naturally beautiful on account of the charming rocky or woodland scenery by which they are surrounded. Just opposite Shepley Glen, one of the most romantic of Yorkshire dales, are one or two little paper-mills, close by the River Aire. The machinery of these is turned by water-power, and it is hardly possible to conceive anything in the way of manufactory surroundings more picturesque. This was simply Nature's adornment, without the interference of art; but, where that does not exist, one cannot help thinking that workmen would be happier and more contented if their workshops and places of business were made artificially interesting, instead of the bare and, in many cases, repulsive places they too often are. I have seen ordinary artisans' shops made beautiful with Ivy and Convolvulus, and a village blacksmith's garden the best in the parish; while even the signalmen on our railways spend part of their leisure time in growing pot-plants, or hardy flowers. It is pleasant to

see working men bring the fresh sweetness of flowers near their dwellings, so as to make them a part of their every-day existence; and, happily, this taste is rapidly extending amongst all classes of society, both in town and country.

F. W. BURBIDGE.

FERNS FOR THE MARKET.

OF all Ferns cultivated for market purposes, the best is the common Maiden-hair, *Adiantum cuneatum*, which is of moderate growth, stands well in room windows, and is the best of all Ferns for bouquet and button-hole work, or for mixing with every description of cut flowers. Its pretty fronds excite more attention than those of any other variety, and, taking it altogether, it is a Fern with which it is scarcely possible to overstock the market. For these past few years, however, *Adiantum concinnum latum* has been held in considerable estimation in the market, and this has been so far fortunate for growers, as this kind can be raised to any extent by means of spores, the produce of which, in twelve months, may be grown into large and handsome specimens, well furnished with rosy-tinted young fronds. This variety of Fern is, however, too tender for general market work; it will not stand draughts nor any hardship, and the fronds, when cut, last but a very short time. For these reasons its market value has somewhat decreased. Of this sort thousands were grown two or three years ago by Mr. Herbst, of Richmond, but now he has scarcely a plant of it on his premises, simply because they have fallen in public estimation. *Adiantum decorum* still maintains a prominent position in the market; it is a fast grower and a pretty variety, not very unlike *A. cuneatum*. With some, *A. hispidulum* is a favourite, as are also *A. formosum*, and the strong-growing broad-leaved kinds, such as *A. trapeziforme*, *macrophyllum*, and *Catherinæ*; in fact, most of the Maiden-hairs, if grown into nice little specimens soon command purchasers, but many of them are too expensive and slow-growing to be remunerative. Next in demand to the Maiden-hairs are the different kinds of *Pteris*, of which *serrulata* and *tremula*, and their varieties, are most in request. The common *Pteris serrulata* is a graceful little Fern, but it takes a year or fifteen months to get a nice saleable specimen of it. It does not, however, require much pot room, and not only are plants of it useful in themselves, but the fronds stand well when cut, a property which constitutes one of its greatest advantages. Of this species there is a variety in cultivation under the name of *P. s. major*, which is one of the most graceful of Ferns when grown in pots. Its fronds are, sometimes, 3 feet in length, branched and beautifully arched, and a well-grown plant of it forms a grand object either for hall or table decoration. Of this sort it is impossible to get a sufficient stock, for the demand for it always exceeds the supply. It is somewhat difficult to increase; hence its scarcity. It produces an abundance of fertile fronds, but the spores never germinate with any kind of certainty; therefore, the only way in which it can be increased with satisfaction is by division, which is a slow process, especially for market purposes. Some cultivators have succeeded in getting a crested form of this Fern, quite as free-growing as the original, and, therefore, a better market plant. *Pteris umbrosa* is another good market Fern, and one much sought after on account of its ability to stand, uninjured, in heated rooms for a considerable length of time, and its robust deep green fronds clearly indicate this fact. It may be readily increased by means of spores. But of all Ferns propagated in that way, *Pteris tremula* stands, perhaps, in the foremost rank, and it is a variety which is, likewise, highly esteemed in the market. Under good cultivation, it makes excellent saleable plants at the end of twelve months, starting with the seedling stage; but it is frequently grown for six months longer. It is of little value for affording fronds for cutting, but it makes a very desirable pot plant. *Dicksonia antarctica* makes a fine market Fern, when in a young state; for this purpose, after the spores germinate, they should be pricked off into little clumps, and, as soon as a few small fronds have been formed, they should be potted off, placing two or three plants, without separation, in each pot. By this means nice bushy and effective specimens are obtained fit for sale.

NOTES OF THE WEEK.

— THE Rhododendrons in the conservatory at Enville have been very fine during the past spring. *R. Nuttallii* has borne flowers fully 7 inches across, and other varieties, such as *R. javanicum*, *R. Gibsoni*, and *R. Edgeworthii* have been remarkably floriferous. Few plants are more attractive in spring in cool conservatories than these Rhododendrons when well grown.

— ON Monday afternoon Weston Park, the first public recreation ground secured for Sheffield, was opened with some ceremony. The park was the property of Miss Harrison, and on her decease was purchased by the town for £15,000. The residence is being converted into a museum.

— AT the Hale Farm Nurseries, Tottenham, may now be seen in flower, the Yellow Pæony (*P. Wittemanniana*), the singular-looking *Iris Iberica*, and the delicate and showy *Iberis jucunda*, also a clump of *Gentiana verna*, with at least fifty fully expanded blossoms, *Pulmonaria davurica*, the curious *P. maritima*, *Rubus arcticus*, *Eritrichium nanum*, and *Erythronium giganteum*. Among Primulaceæ may be mentioned the six varieties of *Primula cortusoides amoena*, called, sometimes, *P. Veitchii*.

— ON Thursday next, the 14th inst., Mr. W. Bull intends offering part of his collection of Orchids for sale at Stevens's. The collection comprises some of the rarest species of *Cattleya*, *Vanda*, *Odontoglossum*, and *Phalænopsis*, including the hitherto rare and valuable *P. Lobbii*, besides other novelties, the plants being fully established, and in a state of perfect health and vigour. One of the lots will consist of the finest plant of *Masdevallia Lindeni* in cultivation; quite recently it bore eleven fine flowers, seven of which were fully expanded at the time.

— THE new arboretum at Walsall was opened the other day, the formal ceremony being performed by Lady Hatherton in the presence of several thousands of the inhabitants. The greater part of the site is the property of Lord Hatherton, who has contributed £500 towards the cost of the undertaking. The area of the arboretum is 18 acres, of which $7\frac{1}{2}$ acres are covered by ornamental waters. The grounds have been laid out with taste, and the whole enterprise will be a valuable acquisition to the inhabitants of the Black Country.

— THE glorious uncertainty and irregularity of our climate could scarcely be better illustrated than by the character of the weather during the last three weeks. On several occasions during last week the thermometer registered 5° of frost; fortunately everything was dry, and, therefore, little real damage was done. Of course, 5° of frost is nothing unusual in May, but, coming after the preceding hot weather, which had brought everything forward with a rush, its effect would have been disastrous, had not dry weather prevailed. There are, at present, prospects of a very good fruit crop.

— A MEMBER of the Pharmaceutical Society was preparing a lecture on edible and noxious Fungi, when he accidentally swallowed a quantity of spores of a large species of Puff-ball (*Lycoperdon giganteum*), and, within the space of an hour-and-a-half, was seized with severe illness, the most violent symptoms of which could not be subdued until nine days after the first attack. "So much," observed the sufferer, writing of his illness, "for eating 'a devil's snuff-box.'" The Giant Puff-ball, we need scarcely say, is edible in a young state, but its matured spores ought certainly to be avoided.

— THE collection of Economic Entomology at Bethnal Green has recently received an interesting addition in the shape of a few cases of exotic galls, some from the Himalayas, originally collected, we believe, by Dr. Hooker; and some from Utah, collected by Mr. Andrew Murray during his late visit to that country. Some of these are very curious, inasmuch as they show the extraordinary forms that vegetation assumes under the irritation of gall insects, and those belonging to the Oaks are interesting from their relation to the Oak-galls of our own country. The galls upon our native Oaks (possibly upon all Oaks) are produced by various species of a family of hymenopterous insects named Cynips, a black or brownish four-winged fly, and which have received various specific names, derived from the part of the Oak to which they are confined, or from some peculiarity in the form or appearance of the gall itself. They occur upon the leaf in various forms, on the leaf-stalk in various forms, on the flower-stalk, on the flower, on the acorn, on the buds, on the twigs, on the roots, and are all so like each other, differing chiefly in size and degree of colour and markings, that it is almost impossible for anyone to dispute the Darwinian origin of the whole from a common ancestor, whose descendants have been modified by their special predilection for, and adhesion to, some particular part of the plant. The species of gall which we have figured in another page of to-day's paper is produced by *Cynips lignicola*, or,

as it is sometimes called, *C. Quercus petioli*, and is generally known as the "marble gall," from its being of the size and shape of a boy's marble.

— A FERNERY has been purchased from Mr. Sam. Mendel, and offered to the Peel Park Committee of the Salford Corporation as a nucleus of a winter garden.

— MR. J. H. LEWIS, of Liverpool, proposes to issue twenty sets of British Rubi, if names of subscribers are to hand by June 1. Each set will contain examples of twenty forms. Each example will show two flowering-shoots—in flower and in fruit—and two pieces of barren shoot—young and old. In gathering, avoidance will be given to hedgerow-clipped plants, and preference shown, in this fasciculus, to those that exhibit characters corresponding to Professor Babington's species and varieties, as described in "British Rubi," 1869. If encouragement be given to this fasciculus, others will be issued having more regard to intermediate and dubious forms. The price will be £1 per set.

— AT a recent meeting of fruit-growers in Melbourne, Australia, the sparrow difficulty was the principal, although not the ostensible, subject of discussion. To such dimensions have the losses of stone and small fruits attained that the growers feel themselves face to face with the most serious obstacle they have ever had to encounter. By the introduction of the English sparrow the balance of Nature has been completely upset; the native birds which used to visit the gardens at certain seasons—many of them insect destroyers—have been driven away by the pugnacious strangers, to whose rapacity fruits, grain, and seeds are alike sacrificed.

— MR. BRIGGS, of Yuba City, California, has a solid block of fruit trees covering 210 acres. The soil is a light sandy loam, and is constantly cultivated with ploughs through the whole season. A correspondent of the *Marysville Appeal* writes, that it contains 8,000 Peach trees of sixteen varieties (4,000 being of one variety, the Red May); 3,000 Apricot trees of twelve varieties; 4,000 Cherry trees of twelve varieties; 7,000 Plum trees of fifteen sorts; 2,000 Apple trees of only eight varieties; 1,000 Pear trees, mostly Bartlett's; 1,500 "Cherry Plum" (*P. myrobolana*) trees, and 150 June (Jaune Hâtive) Plum trees. There are also 1,500 Walnut trees (*Juglans regia*) of three sorts. The cost of the land was about 17,000 dollars (£3,400); total cost for orchards, land and all, is less than 30,000 dollars (£6,000), and the estimated value is 50,000 dollars (£10,000).

— THE following are a few of the prices realised at Mr. Micholls's sale, to which allusion was briefly made in last week's number of THE GARDEN (see p. 366):—*Azalea Stella* (5 ft. by 4 ft.), £10 10s.; *A. Chelsoni* (5 ft. 2 in. by $4\frac{1}{2}$ ft.), £11; *Erica Cavendishii* (4 ft. by 4 ft.), £9; *E. Shanonii* (4 ft. by 3 ft.), £9 10s.; *Aphelaxis macrantha purpurea* (5 ft. by 3 ft.), £11 11s.; *Phenocoma Barnesii* (5 ft. by 3 ft.), £12 12s.; *Hedera tulipiferum* ($4\frac{1}{2}$ ft. by 4 ft.), £16; *Dasylium acrotrichum*, £12 12s.; *Gleichenia rupestris* (7 ft. by 5 ft.), £19 19s.; *Nepenthes Hookeri*, £26 5s.; *N. sanguinea*, £14 3s. 6d.; *Cocos Weddelliana* (8 ft. by 7 ft.), £29; *Anthurium Scherzerianum*, "one of the original plants, and the finest specimen, with the highest-coloured flowers in existence," £66. The total sum realised for 639 lots amounted to £1,644 17s.

— THE number of the *Florist* for May contains an excellent coloured illustration of a new hybrid perpetual Rose, raised by Mr. William Paul, and named by him Peach Blossom, the tint being that of a delicate peach-blossom, a colour hitherto unknown amongst hybrid Perpetual Roses. The same number also contains figures of two new dessert Gooseberries, one of which, named Catherine, is a hairy yellow of great size (nearly an inch-and-three-quarters in diameter), and is said to be of good flavour. The other, Benson's Seedling, is a hairy red of tolerably large size, and said to be of exceedingly good quality. It has been awarded a first-class certificate by the Royal Horticultural Society, and is described as a chance seedling, originally taken from a hedge in the neighbourhood of Peterborough.

— IN reference to Mr. Darwin's note on the destruction of Primroses by birds, apparently for the purpose of obtaining the nectar, *Nature* published the other day letters on the subject from various parts of England. At Plymouth, birds are in the habit of thus cutting the flowers of the Polyanthus and Primrose, and in Hampshire the same flowers are attacked by blackbirds, it seems. Dr. Gladstone notices that both Primroses and Crocuses are thus bitten off by sparrows in London gardens, and others remark the habitual destruction of the Crocus in the neighbourhood of Hammersmith by the same birds. On the other hand, persons writing from Hertford and Torquay have examined large beds of Primroses which have not been attacked in this manner. It has been suggested, with some probability, that the birds may be in search of small insects which infest the flowers, and this should apply more forcibly in the case of the Crocus, the nectar-bearing portion of the flower of which is almost buried in the earth.

THE FLOWER GARDEN.

A CYCLAMEN NOOK.

THIS elegant and exotic-looking flower is seldom made to play the conspicuous part it ought to do among the earliest of the spring flowers of the open garden. The Persian species, *C. persicum*, found also in the Greek islands, has become a great favourite among our early-blooming greenhouse plants, and it well deserves the prominence to which it has been promoted. The extreme elegance of its flower-forms, its graceful growth, and the many exquisite varieties which have recently been obtained by careful culture, have secured for it a leading place among the most popular flowers of the day. But its pretty congeners, *C. coum*, *C. europæum*, and their varieties, have not as yet received the same amount of attention as flowers of the

display of rich rosy-tinted flowers, among snow and icicles, could consist of a fair sisterhood of Cyclamens. I had known these prettiest of wild flowers in sheltered nooks among the rocks of the Alps, and nestled between the tufts of April turf in the Roman Campagna, and the green slopes of the Villa Borghese; but it required a few moments' reflection to realise the fact that those pretty porcelain-like creations, whose acquaintance I had first made in Italy, were actually the flowers then seen braving the frosts and snows of ungenial Britain, before the end of January; nevertheless it was so, and they seemed to enjoy their defiance of the northern climate.

The same Cyclamen nook has, however, been seen to far greater advantage in the present season; the winter had been so mild that the Mosses and tender herbage amongst which they grow had already formed a soft green carpeting for them to spread their finely marked leaves upon, and make a rich

A Cyclamen Nook at Heatherbank, Weybridge.

open garden, though they are nearly as beautiful and perfectly hardy; the latter, indeed, being probably a native British plant, or, at all events, occasionally found in a wild state at the present day, in many favourable spots throughout the country, though possibly introduced from the Continent at some remote period.

In the earliest days of the spring of 1873 (indeed, towards the end of January of that year), I saw, for the first time, in a nook prepared for them at Weybridge, a large patch of hardy Cyclamens, of several varieties, flowering as freely as snowdrops in the midst of frost and snow. Their delicate blossoms were of various colours; some white, tipped with carmine; some crimson, tipped with deepest purple-red; and some of a rich blush tone, deepening at the point to glowing crimson. For a moment, one could scarcely believe that this

dark background of many-tinted brown, green, and orange tones, well calculated to set off and contrast with the roseate colouring of the flowers. Great care was taken to prepare that nook, in the first instance, in a situation well fitted for the purpose; with an aspect which the flowers delight in, and the kinds of soil most favourable to their growth. As will be seen by the illustration, the place especially selected for the purpose is partially covered by a canopy of Laurel, in the soft shadow of which flowers of the white variety, tipped with carmine, positively glisten like gems. In the front, to complete the desired degree of shelter, some large masses of rock have been placed, among which seeds have scattered themselves, from which some of the finest plants have sprung. The prevailing tones of the flowers of *C. coum* are shades of full pearly blush, tipped with crimson. The variety known as *C. vernum*

has flowers of delicate crimson, tipped with deepest carmine. This is the kind most commonly found in Italy, the foliage of which, though small, is very beautifully veined and marked. *C. ibericum*, a Spanish kind, might almost be considered a distinct species, the flowers being deep crimson, and the foliage of a dark green, almost without maculation. *C. cœm album*, the white variety, with its crimson tip, is, perhaps, the most attractive of all as to the flowers, but the foliage, like that of *C. ibericum*, is without variegation. The variety with the largest flowers, and tallest flower-stalks, is undoubtedly *C. Atkinsii*, a hybrid obtained from *C. album* and *C. persicum*. Although one of the parents (*persicum*) is too tender to bear our winters in the open air, the descendant is perfectly hardy, and its brilliant white and crimson flowers figure conspicuously in the accompanying illustration on the right side of the little picture, in the deep shadow cast by the massive foliage of a protecting Laurel.

This "Cyclamen nook" has been quite the pet of the whole surrounding neighbourhood. Friends stopped each other, defying wintry winds, to ask about its progress—were the Cyclamens in bud? were they in flower? were they at their best? how did they bear the nipping of the cold east blasts? These, and a score of other questions were anxiously asked. "The nook" was a novelty most keenly appreciated; those red-stemmed sturdy little beauties, recklessly coming into full bloom almost as early as the Snowdrops, and long before the Crocuses, enlisted the sympathies of every garden lover for miles round; and preparations will be rife next autumn in many a garden thereabouts to prepare rival "nooks;" questions without end having already been asked, and as freely answered, as to how to plant? the best soil for the purpose? and the best aspect? Many flower-lovers, who are not botanists, will be glad to know that they may have an autumnal as well as a spring nook of Cyclamens; the *C. hederæfolium* being a September-flowering kind. This plant—the Ivy-leaved, as its name implies—is a native of the mountains of the Austrian Tyrol, and many varieties will doubtless be obtained from it if there should be a demand for autumnal-flowering kinds. It is a very handsome plant, the leaves being more finely shaped, and also more beautifully marked, than those of any other species. The pretty-sounding name, Cyclamen, is formed of the Greek word *κύκλος* (*cyclos*), a circle, in allusion to the numerous circular coils of the fruit-stalk. When the flowers fade, the pedicels twist up like a screw, enclosing the germen in the centre, and, lying close to the ground among the leaves, remain in that position till the seeds ripen.

H. N. H.

BEDDING PLANTS.

WITH an outdoor temperature equal to that of an ice-house at night, and somewhat like a Turkish bath in the day-time, I envy not the cultivator who has the care of a large collection of bedding plants in small pots. The mere labour of watering in such weather is very great. The plants would do far better, and not require a fourth of the labour, if they were turned out of the pots into some structure of a temporary character, where the necessary protection could be easily applied. Of course, although we are now getting fine weather in the daytime, which is pushing forward vegetation to some extent, it is too soon yet to think of bedding-out; for the chances are that the early part of this month will continue to be cold, and the nights frosty. There are various ways of providing cheap temporary places for saving labour in the management of bedding plants; and, in fact, almost anything is better than keeping them baking in small pots. In some places this accommodation is provided by opening trenches 4 or 5 feet wide where the ground is vacant in the vegetable quarters. I, however, object, for various reasons, to thus using ground intended hereafter for vegetables, because, in the first place, the ground in the immediate neighbourhood gets trampled so much as to render it unfit for cropping for some time; secondly, I am in favour of a hard surface for standing the plants on when turned out of the pots, with just sufficient soil placed firmly between and over the balls to induce them to make a host of fibrous roots,

but not deep enough to encourage too much growth; and thirdly, it is always desirable to economise labour by placing those extemporised nurseries as near the water supply as possible. Having, therefore, selected a suitable spot in a sheltered position, the next consideration is the arrangement of the surface into handy-sized beds to facilitate the necessary watering and covering. The former will be reduced to a minimum, but the coverings will probably require to be placed every evening. In nearly all gardens there is, or ought to be, a number of stout boards or planks for the convenience of carrying out any necessary alterations in winter cleanly and expeditiously; and with those, and some short stakes driven alternately on each side to keep the planks firmly on the edge in the required position, a number of temporary wooden frames will be formed in a very short time. Stout laths or Holly hock stakes may be laid across, at intervals of 3 feet, to support the mats or other protecting materials used, and a nail may be driven through the ends to keep them in their proper places. About 6 feet is a very convenient width for watering or covering. I have sometimes, when short of planks, used bundles of Pea stakes laid end to end for forming the outside of temporary bedding-plant protectors, and, with an extra band round them to keep the sprays close together, they form no bad substitute for planks. However, anyone with a little ingenuity will always discover something near at hand suitable for the purpose. I may say also that much may be done to facilitate arrangements of this kind in winter, when there is not so much pressure upon any department. Assuming that the surface of the ground is level and perfectly hard, about 4 inches of soil may be placed in the frame, and the plants at once planted out almost closely together, and the soil packed in firmly round the balls. Tricolor, Bicolor, and all other Geraniums that are grown in pots for bedding, may be turned out, and the pots used again for potting off Coleus, Iresines, Fuchsias, &c. In this way our pots do duty sometimes two or three times during the spring. Verbenas, Petunias, Ageratums, Perillas, &c. are better pricked off into boxes, and the growth duly pinched in to keep them sturdy and dwarf. When the planting season arrives, the plants may easily be lifted and the balls divided without any serious check being felt. In fact, this turning out into a cool open air structure a month or so before finally planting out is a decided advantage, even to the plants, without taking into consideration the important saving of labour.

E. HOBDAV.

THE WALLFLOWER.

Is not this valuable spring-blooming plant worthy of much wider cultivation, and a more careful degree of selection, than it at present receives? I regard the Wallflower as the most pleasing of all hardy early-blooming biennials, as, in addition to rich hues of colour, it also possesses the most delightful perfumes. I have seen the single Blood Red growing by the acre in market-gardens about here; but, as the flowers are cut as fast as they are ready for bunching, the effect of a grand mass of rich colour is never seen. How is it that our finest London Market variety is so little met with in country districts? I often ask myself the question; but the reason is clear and simple. No spring flower is so eagerly sought after by bees; and, as they continually flit hither and thither from plant to plant, and from garden to garden, it is obvious that they must be continually fertilising the flowers of one plant with the pollen of others of a different hue of colour, and, under these circumstances, it would be impossible to maintain pure a strain of the Wallflower, let the colour be ever so good. At least, it could not be maintained so by seed, but it might be done by the propagation of anything specially good by cuttings. There is but one other resource for the amateur or gardener who wishes to annually possess pure strains of the Wallflower, and that is, to purchase seed from some reliable source, where one colour only is grown except at remote distances from any other. I have, of late, become so conscious of the great beauty and fine quality of some of our single kinds, that I have this spring made a selection of certain forms and colours for naming, and to be propagated by cuttings, so that their fine features may be truthfully maintained. Thus, of these, I have selected six a

possessing notable merits. Warrior has a fine pip of good form and substance, well expanded, and in colour intense rich crimson. It grows to an average height of 18 inches when the plants are strong, and is most effective when in full bloom. Giant Red partakes somewhat of the robust habit of growth peculiar to the strain known as Young's Blood Red, but has a more compact growth, and is about 14 inches in height; the pip is of great size and substance, and fully expands without curling; the colour is bright crimson-red, and the variety is one of the finest I have ever seen. The Dwarf, compact red, presents a form that must become most valuable for spring bedding purposes, its height being about 10 inches, whilst it also possesses a close branching habit. It blooms early and freely, and is also of a deep crimson-red hue of colour; it will make a capital companion variety to the Belvoir Castle Yellow. We have at times obtained from the Continent novel coloured strains of the Wallflower, but they are remarkable for their straggling habit of growth and looseness of the flowers. Of these I have made a selection of a variety that has purplish plum-coloured flowers of fair quality, and the habit of the plant is better than that of Wallflowers generally, being about 15 inches in height, and even more. I call this kind Plumripe. Good yellow Wallflowers, when pure in colour, and of an even habit of growth, make very effective spring beds. This is especially the case with a good strain of the Belvoir Castle Yellow, a variety that has several synonyms, but its large use by Mr. Ingram, at Belvoir, ere it was commonly known elsewhere, justifies the general use of the designation I have given it. Its merits are a very dwarf compact branching habit; early blooming; colour, pure orange-yellow, and a most effective bedder. For a fine border kind, however, I must give the palm to Cloth of Gold, a clear golden-yellow flower, large, flat, and rounded, and very handsome. It grows to a height of 16 inches, and blooms for a long period. The latest novelty in single Wallflowers is a variegated kind, the leaves being edged and flaked with yellow, and the flowers striped yellow and crimson. It is quite hardy, and will make a pretty pot plant for a cool house. Seed of the single Wallflower should be sown in the three first months of the year to secure strong plants, and an early bloom for the next spring. Our market-gardeners sow their seed usually on a fine day in January, and are oftentimes enabled to cut flowers at the ensuing Christmas. Of the double kind little is now seen except the yellow, which is common, and makes a very attractive border plant. It is a great favourite with cottagers, as plants, if carefully looked after, will continue to grow and flower for several years. There is also sometimes to be met with a fine double chocolate-brown kind that is equally early and vigorous, but the least known and most richly coloured of all is the deep crimson, a fine and distinct variety. It is in all respects, except colour, an exact duplicate of the yellow, but I have not seen it for many years. These double kinds are easily propagated by cuttings taken off after the plant has flowered, as the young shoots are then firm and able to resist damp. A shady place, sharp sandy soil, and a handlight are all the remaining requisites to ensure a good stock of plants. I have seen the exhibits in the class for six double Wallflowers, staged at the spring show at South Kensington, for several years past, but the yellow kind only has been staged. If the class is to be continued, I hope to see more variety in nature.

A. D.

STOCKS.

ONE of the most common, and, at the same time, one of the sweetest of garden flowers, is the Ten-week Stock, popularly known under the homely name of Gilliflower—a summer-blooming plant as indispensable to our gardens as the Rose. It is said to have come to us from the shores of the Mediterranean; and if the original form, as introduced, could now be compared with the finest types in cultivation, we should be much surprised at the extent of improvement which has been effected in it. As in the case of the Aster, German cultivators have done much in the way of developing finer characteristics than occur in the original species, and hence it has come to be known as the German Ten-week Stock. This Stock that which is most generally cultivated for summer-bloom-

ing, and it is the invariable rule to import its seeds from Germany, where they are saved from plants carefully cultivated in pots; therefore, as a general rule, sixty to seventy per cent. of the plants produce double flowers. In some cases, however, the chances of double flowers are very precarious. It is said that such seed plants as have more than the usual number of petals, that is, six or seven instead of four, generally produce double flowers when the seed is again sown. This may be true; but it is no less certain that four-petalled flowers will also produce a large percentage of double blossoms. Still, it would always be well for the cultivator who may be bent on improving a particular kind of Stock to mark plants showing a redundancy of petals, and sow the seed separately with the view of testing the truth of the theory. It is by no means generally known that double Stocks do not produce seed, and that it is obtained only from single flowers, a fact also true with respect to the Chinese Primrose. In a perfectly double Stock there are no such things as stamens or anthers, consequently no pollen, but all flowers on single plants that have five, six, or seven petals, will furnish seeds that produce eighty per cent. of double flowers. The finest strain of this Stock is that known as the large-flowering Pyramidal Ten-week. I have seen magnificent varieties of this come from imported seed—large vigorous-growing plants, branching freely, and producing a huge main spike of double flowers, with numerous branching spikes in succession. Where cut flowers are in request, a bed of these Stocks should be grown to assist in supplying them during the summer. The seed may be sown at any time from the middle of March onward; but it is always well to get Stocks from the seed early, so that plants may be ready for bedding. The seed can be sown thinly in pans or shallow boxes, in a gentle heat, and, as soon as the plants can be handled without injury, they should be transplanted into other pans or boxes, and grown on quickly, at the same time taking care not to draw them so as to make them weak and lanky. There are many places in gardens where a bed or line of Stocks might be grown with advantage; only give them a good rich soil to grow in, and they will amply reward the cultivator. The German growers have a formidable list of kinds, many of which are more curious than showy. There are, however, sure to be sufficient leading colours among them, such as crimson, rose, purple, violet, and white, to yield distinct and pleasing hues. There is a strain of English selected Stocks known as Pyramidal, which are of tall growth, and remarkable for the large pyramids of fine flowers which they produce; but they are by no means so generally cultivated as they deserve to be. There is a very distinct type of Stocks known as Wallflower-leaved, which were introduced many years ago from the Grecian Archipelago, and which have shining deep-green leaves, not unlike those of a Wallflower. In all other respects the Wallflower-leaved type is like the ordinary German Stock. One of the finest varieties of this type, and at the same time one of the most beautiful Stocks in cultivation, bears the name of Mauve Beauty, a kind remarkable for its huge compact heads of pale lustrous mauve-coloured flowers. The same treatment as that recommended for the Ten-week Stock will answer for this type of Stock.

The Intermediate Stock, as it is termed, though only a later-flowering selection from or variety of the German Ten-week, may be set down as a distinct type. It is used for pot-culture, to flower in early spring, the seed being sown in July and August. In growth it is dwarf and bushy, and, being very free-blooming, it is well adapted for cultivation in pots. As striking colours are best adapted for this purpose, the varieties may be said to be confined to scarlet, purple, and white. There is a fine strain of this type grown in Scotland, under the name of the East Lothian Intermediate Stock, where it is much used for beds and borders, the cool moist climate of that country appearing to suit it exactly. Instead of sowing Intermediate Stocks at the end of the summer, they should be sown about the end of March in a cold frame, and in May they should be transplanted to the open ground, in which they will flower freely through August, September, and October. In November the double flowers should be all lifted and potted, as it is unsafe to expose them to the risk of wintering in the open ground, and they continue to bloom more or less during the winter in a cold frame or cool house. They should be again

planted out in March, when they will make fresh growth and flower all the summer. The single varieties are also lifted in November, and either potted or planted by the side of a south wall, where they are wintered, and flower and ripen their seed the following summer. They too require a rich light soil, in which they root freely.

There are yet the Brompton Stock and the Queen Stock. The latter differs from the ordinary annual Ten-week Stock in being somewhat shrubby, of larger size, and of perennial duration. The principal varieties are the purple, scarlet, and white—the former being most generally grown. It is a great favourite in cottage gardens round London; and, at this time of the year, dense bushes of it may be met with—a mass of fine double purple blossoms. By some the Brompton Stock is thought to be only a variety of the Queen Stock; and certainly there are many points of resemblance between them, though the latter has a stronger, taller, and less branched growth. There are the crimson, white, and purple varieties. In some country districts, there is a fine form of the crimson or scarlet to be met with in cottage gardens, with long stems of great size and remarkably full double flowers; and there is also a very fine form of the white Brompton in cultivation. The seed should be sown in April and May, either in a gentle heat or on a warm border in the open air; the plants should be pricked out into beds and grown on during the summer, and in August and September planted out where they are to flower. They frequently suffer during the winter from hard weather; and, it is not a little remarkable, that these biennial Stocks appear to have suffered more during the past dry winter than they did during the very wet winter of 1872-73. An old authority states that the true Queen Stock is rough on the under part of the leaf, and woolly. The Brompton Stock has leaves that are smooth on both sides. The seed of the white Brompton Stock is of a pale brown colour; that of the white Queen of quite a dark tint. A great deal of confusion is caused by one being frequently sold for the other. QUO.

NEW VARIETIES OF CHRISTMAS ROSE.

(HELLEBORUS.)

THE following remarks on this subject, by M. E. Rodigas, appear in the last number of the *Bulletin d'Arboriculture*:—Among those varieties of Helleborus which are considered to be true species, several possess a really ornamental character, and deserve to be better known. Such are *H. niger*, with its large-flowered variety, *H. n. maximus*; *H. purpureus*, which has flowers of a fine velvety purple; and especially *H. abchasicus* A. Br. (mentioned in Booth's catalogue of 1851, and two years later in the seed catalogue of the Botanic Garden at Berlin), and *H. olympicus* Bot. Reg., the flowers of which are larger and more rosy, and which is, probably, only a more perfect form of *H. atrorubens* Wald. The discovery of the last-named species dates back to 1822. It is a native of Hungary, while *H. abchasicus* was first found, fifteen years since, on the slopes of the Caucasus facing the Black Sea. Seeing these plants in flower, side by side, we have often doubted their specific difference, and a personal experience of them fully confirms this view. In fact, repeated sowings which we have made of seeds of *H. abchasicus* fertilised with *H. olympicus*, and *vice versa*, have produced forms possessing, in turns, all the characteristics of several species admitted by authors, so that *H. abchasicus*, A. B., *H. atrorubens* Wald., *H. purpurascens* Wald., and *H. olympicus* Bot. Reg., might well be reduced to a single type, of which (following the recognised laws of priority in botanical nomenclature) the name should properly be *H. atrorubens* Wald. Whatever opinion may be formed of this scientific question, at which we merely glance here, the plants possess a twofold value for gardens on account of their early flowering and their handsome foliage. Not only do their flowers withstand all the rigours of wintry frost and snow, but the verdure and vigorous growth of their leaves distinguish these plants throughout the whole year. In the course of the sowings to which we have made allusion, M. le Dr. Rodigas has obtained, in his gardens at Saint Trond, several varieties, which add to the other good qualities of the type the additional merit of new tints of colour in the flowers

Of these varieties the following are among the most remarkable:—

H. ABCHASICUS VAR. *FLORE ROSEO* (Rod.), distinguished by rosy tint, which, in fine lines or streaks, suffuses the paler ground of the flower.

H. A. VAR. *FL. PURPUREO-LEVIGATO* (Rod.), remarkable for the round form and reddish-purple colour of its flowers.

H. A. VAR. *FL. ALBO* (Rod.) is, perhaps, the most remarkable of these varieties, its pure white flowers, slightly tinted on the margins with rose, presenting a marked contrast to the flowers of the other kinds.

H. A. VAR. *FL. PURPUREO* (Rod.), in its foliage and the colour of its flowers, resembles *H. purpurascens*, Wald., although it is certainly a seedling from *H. abchasicus*. Its flowers are not so large as those of the parent, but they are perfect in form, and their purplish tint is very striking.

H. A. VAR. *FL. LUTEOLO* (Rod.).—This variety is remarkable both for the large size of its flowers, and for the yellowish tinge which suffuses their green ground-colour.

All these varieties are well adapted for the embellishment of the flower garden, and, if re-potted in autumn, may be kept long while in bloom as window plants. Their culture is exceedingly simple. Ordinary garden-soil, half-sandy and half-clay, provided it be not too poor, suits them admirably. In dry and very sandy soil, they should receive occasional waterings during the summer, or there is a risk of their not blooming well in the following spring. The plants are multiplied by division of the stools in spring or autumn.

Peculiar Sport from Pelargonium Mrs. Pollock.

I have sent you a truss of bloom cut from a green sport of Mrs. Pollock in which you will find a considerable amount of the Nosegay element. The colour too, is different from that of Mrs. Pollock. Have you seen anything like it?—J. MITCHELL. [On submitting this to Mr. Peter Grieve, he favoured us with the following reply:—"I should hardly have thought it possible that a sport from Mrs. Pollock could have produced the truss of bloom you have sent me, as the flowers are not of the same colour as the blooms of that variety. I have always found that the blooms of green sports from variegated varieties retained the same shade of colour as that of the plants from which they had sported, although, generally, of increased vigour. Moreover, neither of the parents of Mrs. Pollock were of the Nosegay section. The family of the modern Zonal Pelargonium is, however, somewhat analogous to the great Anglo-Saxon race, viz., composed of various elements; and, this circumstance may to some extent, account for the extraordinary sport in question. If your correspondent will refer to 'Grieve's History of the Variegated Zonal Pelargonium,' he will find at page 21, the following pedigree of Mrs. Pollock:—"In the summer of 1855, I fertilised blooms of the old variety named Cottage Maid with pollen taken from Golden Chain, and the result of this cross was two distinct varieties, both of them improvements upon their pollen parent. They were named respectively Golden Tom Thumb and Golden Cerise Unique. During the following summer, blooms of the Emperor of the French were fertilised by the pollen of Golden Tom Thumb, and this produced a variety which was named Gold Pheasant, a decided improvement upon its pollen parent and inferior only to Mrs. Pollock, which last, together with Sunset were the produce of the two following years, and were obtained between Emperor of the French and Gold Pheasant, making the latter the pollen parent."]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Heather-thatched Summer-houses.—Can any of your correspondents tell me how to thatch a summer-house with Heather? The roof is domed and supported on wooden piers.—M.

Iris tomiolopha.—This showy species is now in bloom in Mr. Bullock's establishment at Chelsea. Its foliage is about a foot in height, and the scape which is about as long as the foliage, bears a large lilac flower with purple spots. It is a native of China, and has been fully described in the *Journal of Botany*. It does admirably as a pot plant in a cool house or pit, although a warm sheltered border is the place for it when established.—B.

Alyssum saxatile.—From the middle of April to the middle of May, there is no more showy or beautiful plant in the spring garden than this *Alyssum*: its bright golden colour being the most pleasing of all yellows. Three years ago I planted out a row of nine strong plants, which have been allowed to remain untouched, and now they make a solid mass of colour, 9 feet long and 2 feet in width. These plants consist of the compact-growing variety of the *Alyssum*, and were originally raised from seed, from which plants may be obtained as readily as Wallflowers, and, if it be sown now, strong blooming plants next spring should be the result. Propagation by means of cuttings is also a good mode of increasing the stock; which should be put in under hand lights as early in summer as good firm wood can be had.—BEDFORD.

GARDEN DESTROYERS.

OAK-APPLES OR GALLS.

THESE are produced by an insect known to entomologists under the name of *Cynips Quercus-petiole*, which deposits its eggs in the tender bark of the young twigs of the Oak. Soon afterwards the portion of the bark in which an egg has been deposited begins to swell, and ultimately forms a rounded tumour or excrescence, sometimes over an inch in diameter. "On cutting into these galls," says Dr. Fitch, "the small limb on which they grow is found to have its wood thickened or swollen, and, over it, forming the chief bulk of the tumour, is a corky substance of a yellowish-brown or snuff colour, between which and the wood are several small hard grains resembling seeds, each having a cavity in its centre), in which, doubled together, lies a soft, white, footless worm or maggot. This, on completing its growth, changes to a pupa in the same cell, and, subsequently, into a fly; whereupon, to escape from its confinement, it gnaws through the corky substance and the external bark, thus producing those small perforations like pin-holes, which are always seen in these tumours after the insects have made their exit therefrom." Fig. 2 in our illustration represents a section of one of these galls cut through the middle, and showing the central cavity in which the grub grew to maturity, prior to eating its way to the outside, through the channel which is also shown. The injury done to Oak plantations by these insects is sometimes very great. A few years since they appeared in such numbers in the counties of Devon, Cornwall, Dorset, and Somerset, as to create quite a panic among the landowners, who were threatened with the entire loss of their Oak plantations. Some of the trees withered and died, others had their leading shoots killed, while the younger trees were seriously checked in their growth. A remarkable effect which these galls produced on the larger trees is thus recorded by a gentleman, writing at the time from the neighbourhood of Worcester:—"The mischief is that the Oaks are certainly rendered barren by these hard gall-nuts, and, wherever they occur on the larger trees, there are no Acorns at all produced." There is another species of *Cynips* which deposits its eggs in the same manner in the leaves of the Oak, causing them to swell similarly. The tumours, however, produced by this insect are soft and much smaller than the bark-galls. In both cases it is probable that the parent insect, when depositing her eggs, injects with each a small quantity of some acrid secretion which has a specific effect in so irritating the tissues of the bark or leaf that they at once commence to swell and produce the spherical induration which forms the *nidus* of the future larva.

THE GARDEN IN THE HOUSE.

BALCONY GARDENING.

WITH very little outlay or trouble, a balcony may be made a mass of bloom during a great part of the season, and its decoration affords pleasant occupation. If it be covered, I would suggest, first, that Virginian Creeper be trained over the roof, as nothing with which I am acquainted grows faster, and its colour, in summer, is a bright green, while in autumn it becomes a mass of glowing red. It should be planted in a tub or box, placed at the end of the balcony, along the front of which should be trained Creepers, such as Clematises, and these should also be planted in pots or boxes at each end of the balcony. If the latter be very long, however, some may be placed in the centre as well. On the pillars or supports, Honeysuckle, Passion-flower, and Jasmine might be trained with advantage, and neat baskets suspended between the pillars have a fine effect, filled, say, one with a fine-leaved Coleus, surrounded with blue Convolvuluses to hang down all round it. Another might contain a white and pink Fuchsia, surrounded by blue Lobelias; a third might be furnished with

a handsome Calceolaria in the middle, and scarlet Tropæolum to hang round it; and a fourth might consist of a plant of Centaurea, surrounded by Rollison's Unique Geranium. Then, standing at equal distances in pots along the front, might be placed either handsome-flowering plants or shrubs. All the plants which I have mentioned might remain out of doors all the year round, except those in the baskets, some of which may be saved in a small greenhouse if such a convenience be at hand. The cost, however, of filling them afresh every season is but trifling. In autumn I would advise their being filled with variegated Ivies, many of which look lovely drooping down round the edges, and in their centres should be placed Hyacinths, Tulips, Squills, or any spring-blooming bulbs. In the case of balconies which have no roof, but which merely consist of an ornamental railing, arches of iron rods should be placed along the front, lengthways, and covered with creepers, consisting of the varieties above-named, a

basket being suspended from the centre of each arch. An arrangement of this kind has a very good effect. Instead of having large plants along the front, a box, made either of wood or tiles of whatever width is desirable, to run the entire length, might be used filled with bedding plants during the summer months, and in autumn with bulbs and spring-flowering varieties. When purchasing baskets, I should always advise well shaped, but not ornamental worked patterns to be selected, as those with ornamental work on them are much more expensive, and when the plants are in them, little of the ornamental part can be seen.

A. HASSARD.

Upper Norwood.

Mountain Ash tree Insects.—What is the name of the enclosed insects which are destroying small Mountain Ash trees?—M. W. W. [They are a species of *Phyllobius*, named *P. mali*. They usually attack the Apple and Pear and other allied species of the same family as the Mountain Ash. We know of no remedy.—A. M.]

Insects and Flower Fertilisation.—According to Dr. Müller, of Lippstadt, who has recently published an exhaustive treatise on the fertilisation of flowers by insects, it appears that insects are not impelled by their instinct to frequent particular species of plants. This may occur, but it is only in isolated cases, of which he is able to cite only two. In general, insects roam at random over the fields, and light indifferently on any flowers that attract their attention, and it is not uncommon to find them making fruitless search in flowers that contain no honey. This important fact has been generally overlooked by former observers.

Cobæa scandens.—This and its beautiful variegated form are tolerably well known as conservatory climbers of quick and graceful growth, but it is not so well known, that the green-leaved or typical form is one of the best of all climbers for window or balcony culture. If grown in pots and trained inside the window, it flowers earlier and more profusely than when planted outside, but in either position it is a valuable decorative plant, and one well worth general culture as above indicated. It is a native of mountain ranges in Mexico, and bears large bell-shaped flowers of a greenish-purple, with bright golden stamens. The variegated form is rather more tender than its green-leaved kind.—J. L. McFARLANE.

THE ARBORETUM.

OUR PARKS AND WOODLANDS IN SPRING.

SPRING—the season when Nature puts forth her first promise of the glory that shall follow in the leafy days of summer—comes, I fear, to the pent-up multitudes in great cities only with its lengthened days and warm blinks of sunshine. How little do the vast majority of townspeople know or see of the beauty of our English woodlands, lanes, and parks at this enchanting season? Nevertheless, there is in the heart of most townsmen a deeply ingrained love of a garden and its belongings, and it is a hopeful sign of the times in which we live that we have amongst us men with means and sufficient generosity to part with their money to purchase that most elevating and rational of all enjoyments, namely, a public park or garden. Although such places may be wanting in some of the bright features and surroundings of the fine English parks far away in the country, yet they are, to the artisan and toil-worn multitudes that frequent them, a very paradise; and not alone to them, but, to the children of the rising generation in our towns, what the lanes and woodland-meadows are to our country children, a place of healthful resort, where they become acquainted with Nature and her wonderful productions. Many of us can trace our love of flowers to the days of childhood, when we gathered Daisies and Buttercups with other “wildings of Nature,” to be carried home in triumph to deck the cottage window-sill. Nothing has a more humanising effect upon the young than flowers, and those who set apart either a park or garden for the use of their toiling brethren deserve the best thanks of every man who wishes well to his country. Even to those whose lives are spent in the country, spring is peculiarly interesting. The Pine copse, on which, during the short and stormy days of winter, the eye delighted to rest, becomes comparatively dark and sombre when the Larch puts forth its exquisite green and lovely rose-coloured catkins. Than the Plane, too, no tree in our English woodlands or parks is, at this season, more ornamental, its varied tints being most remarkable; some trees look as if clothed in dark bronze, others in the deepest olive-green. The perfect symmetry of outline of the Plane, too, makes it one of the most striking objects in our landscapes. The Gean and double-blossomed Cherry are likewise lovely objects, perfect in outline, and being covered, as it were, with a sheet of purest snow, contrast strikingly with their green surroundings. It is a matter of regret that the Birch does not occupy a more prominent place than it does in our parks. All who have seen it in its natural habitat, on mountain passes and wild gorges; will, I feel sure, like Sir Walter Scott, term it the “lady of the woods.” Even in winter, we have no native tree to equal it in gracefulness, and, when clothed with young leaves, the perfume which they exhale when refreshed by evening dew or a passing shower, is most delightful. Of the tree “with boughs that quake at every breath, we can hardly have too many,” says Sir Walter Scott; and he planted about 100,000 Birches round Abbotsford. The Hawthorn is so indispensable that few parks or woodlands are without it; next to the Yew and the Oak, it is the most durable and long-lived of our native trees, and, perhaps, more historical and poetical associations cluster around it than surround all our other trees put together. About the durability of our native Hawthorn there can be no doubt; Scott set the age of the “Whitehope tree” at 300 years; it had ceased in his time to put forth leaves, and it stood long afterwards a leafless trunk, giving character to the landscape around it. In early spring as well as in the months of autumn, colours blend most harmoniously; yet, each tree may be known in the distant landscape by its outline. Distinctness of form as well as of colour is, therefore, a point worth the attention of planters. In many of our English counties, the leafy grandeur of our woods and parks is eclipsed at this season by the floral beauty of the Apple and Cherry orchards that surround our rustic homesteads. He would be a dull observer, indeed, who could pass them by without feeling some emotion at a sight so beautiful, while, beneath their shed blooms may often be found a host of our sweetest spring flowers. What a wreath of floral beauty “blooms all

unseen” in the unfrequented glades and recesses of our woodlands; the quantity of wild Primroses in this county (Northumberland) alone is something remarkable. Indeed, many of our woodlands are literally carpeted with them, relieved by the Violet and Wood Anemone, &c. I have not seen the Lily of the Valley growing wild in any of the woods in this county, although it grows plentifully in the highlands of Yorkshire in a wood near Grassington. J. T.

TRANSPLANTING EVERGREENS.

CULTIVATORS, both those who write on the subject and those who practice planting trees and shrubs, are not agreed as to which is the best season of the year for planting evergreen trees and shrubs. Some plant in the autumn, others in the spring—any time from February till the end of May—all hold that their own practice is best. As in every disputed or debateable matter, so in this question a good deal may be said with some show of force on both sides. The advocates of autumn planting say, that an evergreen transplanted at that season has the remainder of the autumn before it to establish itself before winter comes on with its nipping frosts and cutting winds, and before the soil becomes waterlogged and chilled down to its minimum temperature. But those who stand by the practice of spring planting maintain that they altogether avoid the evils implied in the recognised necessity for planting early in autumn, because winter being gone before they begin, their plants have the whole summer before them in which to recover from injuries which are unavoidable in even the most carefully conducted planting. Our own experience and reason are decidedly in favour of spring planting of all kinds of evergreens, about the trans-planting of which there is any difficulty or risk. Many things may be planted at almost any season without risk, while others are particularly unmanageable, except at the most favourable season, and this we have proved—to our own satisfaction—at least—is the period at which the particular sorts begin to grow. At that time life is fresh and buoyant, therefore any check administered is comparatively easily overcome. The influences of genial sunshine, gradually increasing in power along with gentle showers, carrying warmth and nutriment into the earth, alike sustain and accelerate the process of healing the wounds inflicted on the roots. And this is the first process to be accomplished before any progress can be made by the plant in re-establishing itself in its new position. Circumstances are all in favour of this in spring, but the reverse is the case in autumn. Winter is coming on, indeed, is very near before it is generally practicable to engage in planting in the autumn; consequently, the chances of plants recovering from injuries, before they are forced to rest by the increasing cold and decrease of light, are very small indeed. Such are some of the reasons in favour of spring planting, so far as evergreen trees and shrubs are concerned, and the experience of all who have tried it, with the exception of those who have to deal with light dry soils, which are liable to be dried up with the first spring drought. In such soils, no doubt autumn planting is best, but they are the exceptions which to our minds, prove the soundness of the rule. The particular period in spring in which the various classes of evergreen shrubs, and trees may be planted with the greatest safety varies very much; but a good rule to go by is the period at which the particular kinds begin to grow. If the rule is rightly observed, it will be found that ample time may be had for carrying on very extensive operations, and that there is no cause to hasten the work unnecessarily. From the middle of April to the end of May is a pretty long period, considering the length of the day as compared with that of late autumn, and also the ease with which such work may be done owing to the soil being drier and in a more workable condition than in autumn. All tender shrubs and trees may be transplanted in April and May with more safety than in any of the autumn months, and the result at the end of the first twelve months in many cases will be found as two to one in favour of spring planting. This is particularly the case with many of the choice Coniferae, such as Deodars, Wellingtonias, and many others, which should never be transplanted, except they are

be moved many miles, till they have fairly started to grow and made some progress. No one need be afraid of the young growth suffering because of the check. We have lifted many sorts of Coniferae of considerable size late in May, after some progress in growth had been made, and though the leading shoots which had grown 6 or 9 inches or more, at mid-day leaned to one side, quite alarmingly in appearance, for some days after planting, yet every morning they stood as erect and firm as if nothing had happened to them, and in a few days they started growing, and continued to do so at a pace quite equal to the progress made by them in former seasons.

N. B. A.

CUPRESSUS NUTKAENSIS.

THE north-western shores of North America, especially in the vicinity of Nootka Sound, Observatory Inlet, and the Island of Sitcha (places familiar to the reader of "Cook's Voyages"), are the exclusive habitat of this remarkable species of Cypress.

Cones and leaves of Cupressus Nutkaensis.

When the late Dr. Fischer first saw it, he noted it down as a Thujopsis, so much does it resemble that genus in habit and foliage. Later authors, however, prominent among whom is Mr. Gordon, have determined that the tree is most properly classed amongst the Cupressineae, in the sub-order Chamæcyaris, which is distinguished from Cupressus proper, by having only two seeds under each scale of the cone, whereas, the true Cupressus has several. The subject of our notice was first introduced into England in 1851, and the specimens which were then received were kindly supplied by the director of the Botanic Gardens, St. Petersburg, where the young plants were raised in the open air—a sufficient indication of their hardiness. Under favourable conditions, the tree attains in its native habitats a height of 80 to 100 feet, with a bole of over 3 feet in diameter, perfectly straight, and covered with a smooth, soft, dark-coloured bark. The branches spread very much, and are sub-divided into a vast number of smaller pendent ramifications, which in old trees are thickly covered with a highly aromatic resinous exudation. The leaves, in shape, ar-

angement, and colour, bear a remarkable resemblance to those of Thujopsis, being a little brighter, perhaps, and with somewhat less of bluish reflexion. The cones (of which we give an illustration) are solitary, almost sessile, or borne on very short stalks, and are covered with a glaucous pubescence; they are about the size of large Peas. If a twig or branch of this tree is broken or bruised, it exhales a very powerful balsamic odour, and the wood, which produces white and soft timber, also yields in great abundance a very aromatic gum, which, in its appearance and scent, has a strong resemblance to Canada Balsam. The tree is, on account of this property, known on the Continent as the Sapin aromatique. Possessing, as it does, the desirable qualities of beauty, hardiness, and much indifference as to the soil in which it may be planted, we need hardly add another word in commendation of one of our finest evergreens.

W. M.

Value of Pinus Pinaster for Sea-side Planting.—Having, in a recent number of THE GARDEN, had occasion to recommend the Pinus Pinaster for sea-side planting, I now take the liberty of sending a sketch of one of many trees of this kind which grow here. The tree from which the sketch is taken grows within a mile of an exposed sea-coast. It measures 10 feet in circumference at a height of 4 feet from the ground, and is probably from 70 to 80 feet in height. Although these dimensions may be nothing unusual, it is an encouraging fact that timber of this size and beauty can be grown even in a stormy exposure like this.—HERBERT MAXWELL, Monreith, Port William. [The sketch in question is a representation of a fine tree with a bare trunk, many feet in height, surmounted by a noble head of healthy foliage.—ED.]

Dry Rot in Timber.—A remedy has been discovered, by the use of which this destructive enemy to the woodwork of a house may be destroyed or arrested. What is known as "dry rot" is caused by the spores of a species of Fungus (the Merulius lacrymans), which, though they are sometimes carried by currents of air to the scene of their future devastations, are more frequently present in the soil upon which the house is built at the time of erection, and are brought into near contact with the woodwork in the filling up between the joists, or sometimes even in the mortar. Notwithstanding its name, dry rot does not act upon perfectly dry timber, but begins its ravages whenever the wood is in the necessary state of humidity. It may be prevented by mixing with the rubbish used for filling in the floors, the "tank-waste" from alkali works, or the same substance will completely check it if already developed. Tank-waste is of no commercial value, and may be had at alkali works for fetching; it wholly destroys this species of vegetable life, and generates no bad smell whatever.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Daphne pontica.—There is a remarkably fine specimen of this charming sweet-scented shrub growing on the north side of Mr. Goodwyn's residence, at Bedford, where it has been for several weeks literally a mass of bloom. This plant is about 4 feet through one way, and 8 feet the other, and is in the most robust health.—D.

Wistaria frutescens.—Can any of your readers tell me anything about this plant, long since introduced into our gardens, but now evidently either lost entirely or very rare? It is figured in Sweet's "Flower Garden" (1831), p. 104, and is described as being superior to W. sinensis. It has purple flowers and blooms later than W. sinensis, climbs to a great height, and, according to Sweet, is easily propagated by means of cuttings of the young wood placed under a bell glass.—B.

The Wild Cherry.—Allow me to direct the attention of planters to the Wild Cherry or Gean (Prunus avium), as a most desirable tree both for spring and autumn ornamentation. One on which I am now looking has a head like a spreading Oak, is about 40 feet high, and as much in diameter, and one complete mass of beautiful white flowers. While again in autumn it is equally conspicuous on account of its richly tinted foliage. It is a tree well worth planting.—OBSERVER.

How Do Trees Grow?—About twenty-five years ago, new wooden railings were fixed on a garden wall in front of a house in the neighbourhood where I reside. The carpenter, to fasten them more firmly, drove an iron stay into a Sycamore tree which stood in the garden, and fastened the other end to the rails. Assuming that the stay was placed level, I find that it is so at present, and a large excrescence has grown over and around that part of the iron stay which joins the tree. This is one proof that a tree is not "elevated bodily by the development of the roots."—H. ANGWIN.

Early Leafing of Trees.—At page 344, you notice the early leafing of trees in London and its neighbourhood. Down here (Cornwall), the flow of sap is three weeks earlier than usual. Rinding Oaks has been going on here for a week or more, and we might have begun a week sooner if we had had the least idea of their fitness. Last year we could not get a tree to "run" until the middle of May. Hawthorn (May) has been in bloom a week. The Man Orchis and the spotted one, mixed with Blue Bells, all of which are in full flower, were found under trees with foliage quite out on April 25th. Ferns have made new fronds, and the appearance of the woods and hedges makes one think that May is near its close.—H. M.

THE COOMBE WOOD NURSERIES.

By NOEL HUMPHREYS.

LEAVING the rail at the Coombe and Malden station, the walk to these nurseries is one of the pleasantest within ten miles of London. Spring aspects of herb, and tree, and flower, have come on very early and very suddenly this season; and, consequently, the woods and fields, even on May day, were rich with gloriously bright tints of delicate green, and blossoms of many colours. Along the road leading up to that portion of Coombe Wood, known as the Warren, the villa gardens, which here and there vary the regular line of the hedgerows, were literally ablaze with a profuse gush of floral beauty. The White Broom, the double Golden Furze, the double-flowering Cherry, the Laburnum, the Lilacs, and the pink and white Hawthorn flowers, as the bright May sun shone full upon them, and among the loftier Horse Chestnuts, magnificent with grand spikes of flower, both of the red and the white kinds—were really dazzling in their luxuriance. The upper branches of the broad-leaved Lilac were so heavy with their load of bloom that they lolled lazily for support on the tops of the walls or palings, revelling in their beauty. Yet, in the midst of all this luxuriance, the recent frosty nights and keen east winds had not failed to commit some little havoc. The precocious young shoots of the Laurels were nipped and blackened to such an extent that they will not recover during the present season, as were also the tender leaf-buds of the Robinia, just bursting into the graceful pinnate foliage which makes the early spring aspect of that elegant tree more attractive than even when covered with its masses of flowers, white and delicate as flakes of purest snow. The cruel winds had done little mischief among the herbaceous plants, lying lower, as they do, in the sheltered beds and borders of the pretty gardens, where sweet Wallflowers—among them the double yellow and double maroon varieties, and great golden masses of yellow Alyssum were defiantly splendid. It should be noted that a fine contrast in colour to the bright Alyssum is found in *Lunaria biennis*, known by the homely name of "Honesty" in cottage gardens; its subdued, but rich, purple being at once the contrast, and the precisely complementary colour—these respective tones, when closely opposed, making each other look both clearer and brighter. This should be attended to in preparing for the best early spring effects produceable in our flower gardens, for a very glorious effect of colour may be produced by the close juxtaposition of masses of these two free-growing hardy plants, though the chance of such an effect is generally frittered away by a hap-hazard spottiness of arrangement. Ten-week Stocks, of several hues of red and purple, white Arabis, and lavender-toned Aubrietia, had also just become rife with abundant flowers in place of the Daffodils, Crocuses, Snowdrops, and Hepaticas.

Entering the Warren by a road which, while only a foot-path to the general public, is a carriage-way to the handsome residences and grounds which have been leased from portions of the ancient wood, the character of the scene suddenly changes. These residences and their grounds are, fortunately, out of sight among their own shrubberies and plantations; and, therefore, one passes through what appears a centenarian wood, dotted here and there with noble Oaks, whose foliage on the 1st of May was just beginning to unfold itself in various tones of rich olive, contrasting exquisitely with the dove-grey trunks and branches and with the vivid greens of the young foliage of other trees. There were, also, grand old dark-green Hollies, thickly beaded with tightly closed buds of a lighter hue, destined to supply scarlet fruit at Christmastide, but at present so tightly shut, as to comfort us with convincing proof that Christmas is a long way off. Old Hawthorns, too, there were, with rugged twisted trunks and fantastically gnarled branches only half hid by their annual suit of bright green; which was, in its turn, more than half concealed by clusters of buds, like pearly pellets set in clips of green, and by expanded white-petalled, pink-anthered flowers, whose perfumed breath filled the air with delicious sweetness. However, I pushed forward to the main object of my day's excursion, Messrs. Veitch's nursery; and, after reaching another turnpike-road at the end of the Warren, a turn to the right soon brought me to the gates.

Nothing can well be finer in the way of horticultural effect

than the grand avenue which forms the chief entrance to these interesting grounds. Our photographer, from whose reflex of the scene the accompanying engraving was taken, selected his point of view somewhat too near the commencement of the avenue, and so lost the glimpses of exquisite distance formed by the magnificently-foliaged slopes of those portions of Coombe Wood which are still unencroached upon by leasing and building. Also, by taking up his position too much in the very centre of the broad pathway, he was not able to display clearly the plan upon which the avenue has been planted, though the view gives the general aspect of the combination with good effect. Each side of this magnificent avenue consists of two distinct parts or ranges; the external line is formed by finely-grown trees of *Araucaria imbricata* and *Wellingtonias*, planted alternately. Each of these fine specimen trees is between 25 and 30 feet in height, and each is perfect to the very ground. This is very remarkable in regard to the *Araucarias*, which are so sensitive to our alternately damp and sharp frosty nights; and yet there is not a single defective branch in the whole length of this noble line of trees. The *Wellingtonias*, as we know, are entirely hardy, and quite defiant of the rigours of our climate up to a certain period of their growth; but whether they will ever become forest trees with us, rising some 100 or 150 feet high in our treacherous atmosphere, is still a moot question. However that may be, the *Araucarias* and *Wellingtonias* of Messrs. Veitch's avenue certainly look very promising. In front of this line of larger trees is an interesting series of smaller specimens of *Coniferae* of various kinds, carefully selected as to size, in order to render their own line symmetrical, and at the same time not to conceal even the lower portion of the grand *Araucarias* and *Wellingtonias*. Between each of these younger *Conifers* is a fine plant of *Yucca recurva*, which affords a charming variation of foliage very pleasing to the eye. Each plant in this inner line, both *Yucca* and *Conifer*, is encircled by a low evergreen bordering, the space within being filled with hardy Heaths, each circle being furnished with a different kind. These Heaths, rich at the present season with flowers of many tones of colour, impart a sober and subdued richness to the general composition which serves to heighten the effect very agreeably. Among the beautiful young *Coniferae* forming the inner lines of the avenue are, *Retinospora plumosa*, *Cupressus Lawsoniana*, *Cryptomeria elegans*; the foliage of which is of a soft bloomy purple in winter, changing to green in summer; *Retinospora filifera*, with its threadlike pendulous branchlets; *Retinospora aurea gracilis*; *Thujopsis dolabrata*; the Fern-like *Retinospora* (*R. filicoides*); *Abies polita*; a beautiful Japan Spruce, perfectly hardy; *Retinospora aurea*, conspicuous even at a distance, by the bright golden touches of colour at the extremities of the younger branches; a new *Cryptomeria*, softer and more delicate in foliage than *C. elegans*; *Juniperus rigida*, a beautiful Juniper of unusual character, injudiciously termed rigid, inasmuch as its chief feature of attraction is the graceful drooping of its young branchlets. There are also pretty young plants of the Umbrella Pine, which the next generation will see in its splendor, as a tree of 70 or 80 feet high. In short, there is a display of rare and beautiful *Coniferae* in this noble avenue, which is worthy of the spirited introducers of the *Wellingtonia*, and so many other splendid novelties.

The other parts of the nursery which, with a neighbouring plot of land, occupy some forty acres or, perhaps, more, present many features of interest fully equal to those of the grand avenue. There are broad winding roadways leading to the lower grounds, which are bordered with choice shrubs of endless variety, and of the greatest interest to all lovers of horticulture; and, from the higher parts of these roadways, the general view over the lower portions of the nursery is really beautiful, as well as interesting. There are wide expanses of the beautiful *Daphne Cneorum*, a neat little dwarf shrub covered with great trusses of bloom of a soft tender pink; stretches of lemon and orange-flowered *Azaleas*; slopes of purple with the rich hues of *Cryptomeria elegans*, and endless stripes and patches of variously tinted foliage, appearing, as they are spread out far below the eye, like a magnificent carpet of a hundred colours, softened and blended by distance, the whole being backed by the grand banks and slopes of foliage

VIEW IN THE COOMBE WOOD NURSERY.

of the ancient woods beyond. Descending any one of the broad winding roads just alluded to, the visitor is arrested at every turn by the beauty and interest of the shrubs on either side of him, and by the fine landscape effects produced by both form and colour. On one side, perhaps, is a white-flowering Broom, every drooping branch heavy with its snowy burden; next to it is a golden bush of Spanish Gorse, very distinct in character from our fine native species; then comes one of the new Maples, which, as belonging to a family of plants yielding exquisitely tinted foliage, are one of the most valuable additions recently added to our previously rich list of horticultural material—it is *Acer sanguineum*, a graceful tree with crimson-purple foliage; and the next attractive object is a clump of many bushes of the elegant narrow-leaved *Berberis*, *B. stenophylla*, covered with their curious orange-coloured flowers. Next comes a group of variegated Hollies, followed by *Genista daurica*, a perfect blaze of yellow, reflected, as it might seem, farther on, by a great bush of double-flowering Furze. Then comes the purple-leaved Nut, forming such an excellent substitute for the Copper Beech wherever a mass of moderate size, and never greatly-increasing dimensions is required. Next appears a new evergreen Oak, not yet “published,” with leaves as large and solid as those of a Portugal Laurel. Following on, come noble plants of the Lindley and Charles X. Lilacs, profuse in flower as the common Persian kind, and much grander both in the size of the trusses and in the individual flowers. The Lindley variety is of a rich lilac, verging to deep rose, and the Charles X. a light azurean lilac, with the charming addition of a lovely scent.

Descending to the lower grounds, many objects present themselves. There is, for instance, an extensive “rootery,” combined with a pond for the display of aquatic plants, which will form a conspicuous feature in the course of the coming summer; and there are noble hedges formed by fine plants of *Cedrus Deodara* clipped into form, which are certainly interesting features, especially the one which shuts off the Japanese garden, planted some years ago by Mr. James Veitch, and which will be described on a future occasion. There is also a noble display of standard Portugal Laurels, both of the Myrtle-leaved and the ordinary kind, which only require to have a sprinkling of real Oranges artificially attached to their branches to make one fancy himself among the Orange groves of Nice or Cintra. Next comes the grand feature of acres of the newest and choicest Rhododendrons, both standard and bush, which will, in about a fortnight’s time, form a very sea of floral beauty to gaze over. Farther on are choice masses of Azalea; some new varieties of *A. mollis* not yet named, having flowers as large, with petals as broad, as those of the grandest Rhododendron blooms. Farther on are long stretches of hardy Heaths; *Erica vulgaris*, *E. mediterranea alba*, *Ledum intermedium*, and others. After these, one comes upon whole acres of golden Hollies, said to be the finest and most extensive collection in England. Another Deodar hedge encloses and shelters the “stoolery,” where layering, and all other kinds of propagating are going on. Among the plants, of which large stocks are being raised in this sheltered portion of the nursery, are a new white *Wistaria* (imported direct from Japan), with larger flowers and finer foliage than any other known kind; having also the advantage of the foliage being much more advanced at the blooming time than the old varieties. There is also a new lilac kind, somewhat finer flowered than the old variety. Among the new Acers, which are being rapidly produced in numbers, are *A. palmatifidum*, with naturally spreading Palm-like top and deep purple foliage; *A. dissectum*, with leaves which divide themselves almost into filaments, a species which will be much used in bouquet-making instead of Ferns, as it lasts in perfection much longer; *A. pulchrum*, with pinkish-purple leaves as large as those of the common Plane, and very much resembling them in form; *A. roseo-marginatum*, with exquisitely variegated foliage, exhibiting four distinct colours—pale ochre, white, delicate pink, and green. There is also a very small leaved kind, variegated with pink and white, which is not yet named, and is likely to be very attractive.

Among shrubs suited for training against walls are several kinds trained for display against the sides and banks of the conservatories. Among these are three kinds of blue Ceano-

thus, all profusely bloomed; in fact, entirely covered with their neat bunches of deep-toned azure flowers, which, as Byr sang of the Mediterranean Sea, are indeed “darkly, deeply, beautifully blue.” It has been an unusually fine season for the *Ceanothus*; and the hue of its flowers, so unusual in plants suitable for training, has made many a wall glorious with bright azure this season; especially that of a lodge which passed on my way to the nursery, and which many May-day ramblers, like myself, crossed the road to look at more closely. There was also a white kind, with much larger foliage, *C. velutinus*, which, for the sake of variety, should not be overlooked. A new *Escallonia* was also pointed out, with blood-red flowers, larger and more profuse than those of *macrantha*. One of the new *Viburnums* is shown to be a very desirable plant for wall-training, its profuse semi-spheroids of snow-florets and its curiously-plaited foliage being remarkably attractive in character. There were many novelties, also, in herbaceous plants inviting attention; but I have only space to mention two excessively pretty *Primulas*, *P. cortusoides amoena*, with soft lilac flowers; and *P. cortusoides alba*, with deeply-cut petals like those of a *Clarkia*. I was, also, specially attracted by a new double white Daisy, a variety just imported from Germany, much whiter and fuller than any of our own kinds. There was also, in one of the glass houses, another novelty which I cannot forget—a pretty Tea Rose, of deep rich damask tone, which has just been named after the Duchess of Edinburgh.

My excursion to these nurseries was a very pleasant one; and I recommend all who can appreciate the charm of exceptionally fine country scenery, and a noble collection of trees and flowers, to visit the Coombe Wood Nurseries before the glorious music of the nightingale is over.

OXTON HALL.

THIS, the seat of Alfred Harris, Esq., is pleasantly situated on rising ground, about half-way between the village of Oxtou and Tadcaster. The gardens though not extensive, are by no means without interest. The flower-garden is situated on three sides of the hall—east, south, and west. From the east side, which is the carriage entrance, there is an extensive view of the park, about 80 acres in extent, adorned with fine specimens of Oak, Beech, and Chestnut; there are, also, some large and ancient-looking Thorn trees, with flowers of various colours. Nearer the hall, on the Grass, are some large Yews; one, in particular, is about 20 feet high, and 50 feet in diameter, the lower branches resting on the ground. This, when looked at a short distance off, is a handsome object. On the south side is the spring garden, in which are small geometrical beds, cut out of the Grass, and effectively edged with Golden-feather *Pyrethrum*, Golden Thyme, and red and white Daisies. Here, also, are fine specimens of Hollies; and a little to the west of the beds is a Cedar of Lebanon, the trunk of which is 8 feet in circumference at 4 feet from the ground, and about 50 feet high; and the lowest branches from point to point are 40 feet in diameter. Among the trees is a snowy *Mespilus* (*Amelanchier Botryapium*), which, when in flower, is extremely effective. Beyond this there is a pair of unusually fine Turkey Oaks, and east of these are the summer flower-beds. In the conservatory—a lean-to house—there is generally a nice show of flowers, consisting of Azaleas, Camellias, Deutzias, Cyclamens, Cinerarias, Primulas, and similar plants, the Cyclamens being particularly fine during the early months. The kitchen garden is not extensive. It is surrounded by a brick wall 12 feet, and in some places 16 feet, high, well furnished with fruit trees. On the north side of the garden is a Peach and Nectarine house and two Vineries, all lean-to houses. The centre house, which is the early Vinery, is 40 feet long, and is heated by means of hot water pipes. The late Vinery is 90 feet long, and receives no artificial heat whatever; the Peach and Nectarine house is 60 feet long. The gardener, Mr. Croft, states that Peaches, weighing 9 ozs. each, had been gathered out of these houses. On the north side of the hall, at a little distance off, is a small stove, propagating and greenhouse, near which is a small rock-garden, built of the Magnesian limestone, which is so abundant in the neighbourhood. One of the best features of this place is the numerous massive specimens of trees, especially the Beech and Chestnut. Some part would be greatly improved if the bare spaces of ground under the trees were planted with Primroses, Anemones, Squills, and other bulbs, or with patches of such things as *Omphalodes verna*, *Synphytum caucasicum*, &c., which would impart to the whole a much more cheerful appearance than it now has.

THE INDOOR GARDEN.

CALATHEA (MARANTA) ZEBRINA.

few species of this ornamental genus, and indeed, few fine-leafed stove-plants of any description, equal this, when well-grown, either in stately habit or in rich colouring. Like any other good and highly ornate plants, it has the fault of being common in our gardens; but, with those who appreciate a plant for its intrinsic beauty in spite of fashion, this is a subject which is sure to be a favourite. When liberally treated, it produces leaves fully 2 feet in length, of a rich bright green tint, heavily barred or striped with dark velvety-maroon, nearly approaching black. It is valuable alike for stove decoration and for purposes of exhibition. It is the most robust of all the Marantas, if we except *M. Veitchii*, and, as it is a rapid grower, a small plant of it soon develops itself into a good-sized specimen. A compost consisting of one-third fibrous loam, one-third peat, and one-third leaf-mould, with the addition of sufficient sand to keep the whole porous, suits it admirably. The pot in which it is grown should be well-drained, and, when growing, it likes a liberal supply of moisture to the root. Keep up the humidity of the atmosphere, and if syringing is occasionally resorted to, use pure water only, as the slightest amount of mineral or earthy matter held in solution, will spoil the rich freshness of its elegantly arched

Calathea (Maranta) Zebrina.

velvety foliage. During the past season we have had several new species of *Calathea* introduced, but none more effective than the plant now under notice. Q.

STEPHANOTIS FLORIBUNDA.

new white-flowered plants equal this in wax-like purity, gracefulness of form, and delicate perfume; and when blooms of this description are sent to market, they are sure to realise fair prices, even at a time when other flowers are plentiful. Like *Eucharis amazonica*, flowers of the *Stephanotis* are everybody's favourites, and they will last fresh for several days after being cut—a valuable property in the case of flowers grown for market purposes. For button-hole bouquets, about one single flower or buds, backed by a bit of Maiden-hair fern or frond of a *Davallia*, look remarkably well. They are well adapted for bouquets, and are used largely along with the large blossom in all bridal bouquets; while, as a wreath for the hair, nothing can be prettier than a cluster or two of the rounded blossoms and unopened buds of *Stephanotis*, backed by its own thick rich green leaves. In forming wreaths of this description, the old or well developed foliage only should be employed, as the fresh young leaves soon droop and wither after being cut from the plant. The *Stephanotis* is easily propagated by means of cuttings made of the young wood, using a heel of old wood at the base. These should be inserted in a prepared cutting-pot and covered with a bell-glass, placing the pot in a genial bottom-heat, either in a pit or propagating case; in the latter case the bell-glass may be dispensed with. Cuttings of *Stephanotis* root freely at this

season of the year in about a fortnight, but it is a saving of time to purchase plants that are established. These will grow freely if liberally treated, that is, if planted in good fibrous loam, crocks, and leaf-mould, to which sufficient coarse sandstone grit has been added to keep the whole fresh and open. In a compost of this kind the growth made is short-jointed and robust, and much more floriferous than coarser growth made by plants in well-manured composts. The *Stephanotis* likes a warm and genial temperature, the best positions being the roof of a plant-stove or Pine-pit, where it can be trained close to the glass and fully exposed to the sunlight. It grows freely trained on glass partitions or back walls, but rarely flowers so well as when fully exposed nearer the glass. Some growers for market cover the roofs of their forcing houses with this plant, and obtain crops of its pearly, deliciously scented, flowers, for nine or ten months out of the twelve. It grows well in pots, in which it forms a fine exhibition plant, and it is one of the most striking of all stove plants thus treated; but, where quantities of cut blooms are required, pot culture is too troublesome, and does not pay half so well as when the plants are planted out and trained on the roof. They should be pruned in rather closely about December or January, and they may be started into growth as required by means of a little extra heat and moisture. The *Stephanotis* is liable to become infested with mealy bug, which spoils the look of the foliage; and, if this proliferous pest is not kept in check, the clusters of flowers also become infested. The best means of obviating this state of things is extreme cleanliness, for mealy bug rarely appears unless a plant has been neglected or irregularly treated with regard to moisture. Frequent syringings with water at 80° to 100° I have found an excellent preventive of insect pests, and the plants seem to thoroughly enjoy this warm bath daily all through the summer; precautions being taken not to wet the fully-expanded flowers. This seldom happens where flowers are grown for market, every cluster being cut as soon as ever the buds show signs of opening, and the unopened buds are rather benefited by syringing than otherwise. There are but few flowers that pay better than this and *Eucharis amazonica*, and, in all large establishments where choice cut flowers are in demand, a low span-roofed house or large pit might be profitably devoted to the culture of these two plants alone, as they both thrive well under similar treatment and conditions. If it can be managed, this should be done in preference to growing the *Stephanotis* among other plants, especially Pines, since every cultivator who has once had his Pines covered with mealy bug is not likely to run the risk of their again becoming infested. A great deal depends on regular syringing as above directed, and occasional sponging over with soap and water (a very tedious process where the plant covers the roof of a plant-stove); but, if the plant is already infested, nothing is better than repeated doses of Stevenson's insecticide, made a little stronger than is directed in the printed directions, and with this the plant should be syringed at least twice a week. At the time the plants are cut back, they should be carefully cleaned throughout, every insect and speck of dirt being sponged or brushed off, using soft-soap and warm water, and syringing afterwards with clean soft water. C.

CULTURE OF SARRACENIAS.

In nearly every good plant collection may be found plants whose chief value consists in their singularity of form or structure. An ordinary observer may go through a fine collection of stove and greenhouse plants and afterwards remember little about them; but if he sees a *Sarracenia*, a *Cypripedium*, or a *Nepenthes*, his attention will be at once arrested; he will closely examine them, and afterwards remember them with interest. *Sarracenias* have been in cultivation for many years, although, like other curiosities, they never seem to have been generally grown, a circumstance, perhaps, attributable to their constantly failing to grow in a hot and dry temperature, conditions under which the earlier cultivators placed nearly every exotic that chanced to fall into their hands. They are natives of North America and the United States, where they grow by the margins of streams, and in mossy bogs and swamps, and the only

reason why, with us, they are not quite hardy, is our variable climate and the absence of a thick warm covering of snow, which is one of the best of all protectors for tender herbaceous and Alpine plants. They will withstand any amount of cold, but not fluctuating dry winds, sharp black frosts, and drenching rains. One species, *S. purpurea*, or The Huntsman's Cup (once thought to be a specific against small pox), has grown tolerably well planted out on Messrs. Backhouse's rockery, at York, but with nothing like the vigour with which it grows in pots in a moist genial temperature. When well-grown, *Sarracenia*s are valuable for exhibition purposes, as all who have seen Mr. Baines's splendid plants at Nottingham, Bath, Manchester, and elsewhere, can testify. The compost in which they grow best is one composed of fibrous peat pulled to pieces with the fingers and mixed with chopped living *Sphagnum* and broken well-washed crocks. The whole must be on a well-drained bottom; in this respect they are very much like Orchids, they cannot endure stagnant moisture; and, if they are well drained, so that all superfluous moisture passes away readily, it is then almost impossible to give them too much water at the root. In potting, it is best to elevate the crowns a little above the rim of the pot, packing the base of the stems with fibrous peat, and surfacing the whole with fresh living *Sphagnum*. They require about the same temperature as that of a greenhouse in summer, with a little extra heat in winter, and they grow best in the moistest corner of the house, as near the glass as possible, with plenty of air and shading when necessary. They enjoy a full share of light, but cannot endure bright sunshine. It should be borne in mind that all the *Sarracenia*s are essentially bog-plants, and cannot endure anything like a hot dry atmosphere. I remember seeing some of these plants in a hot Orchid-house, where they refused to grow and gradually lost their foliage; after which they were placed in a cool airy pit to rest. This was in the summer time, and, instead of resting, the plants at once showed signs of renewed vigour, and commenced a most luxuriant growth. This fact taught me a lesson in growing these interesting plants that I shall not forget, for every pitcher developed under the above circumstances was larger, fresher, and better coloured than the preceding one, and the plants were much admired both by gardeners and visitors. The following descriptive list includes the species best worth growing, either as decorative plants or for exhibition purposes.

***S. flava*.**—This is one of the freest and best of all, producing pale green pitchers varying from 12 inches to 2 feet in height, and much swollen or expanded like a clarion at the mouth. It is a very variable plant, both as regards the colour and size of its pitchers. One of the best varieties we have ever seen was that exhibited by Mr. Baines at our different metropolitan and provincial exhibitions, where it has been generally admired.

***S. Drummondii*.**—This is one of the most robust of all, and one which makes a noble exhibition plant when well grown, being nearly a yard high and as much through. Its pitchers somewhat resemble those of the last, but are white at the mouth, beautifully netted with deep rosy-purple and green. Like the last, it sports into one or two other forms, of which the one named "alba" is the best. It bears great lurid purple flowers fully 3 inches across, generally in perfection in March and April, but the bloom-buds should be pinched out when good specimens are wanted, as they do not grow so vigorously if allowed to develop flowers.

***S. rubra*.**—This is one of the rarest of all the species, and it does not grow so vigorously as most of the others. Its pitchers are erect and slender, of a cool green colour, finely netted with crimson veins towards their apices.

***S. flavo-purpurea*.**—This is a singular form, possibly a natural hybrid between the last-named species and the richly-coloured *S. purpurea*. In habit it resembles *S. flava*, but is shorter in the pitcher and broader at the mouth, of a soft pale green veined with purple or purplish-crimson. We only know of one plant of this, which is in Mr. B. S. Williams's nursery, at Holloway, and is very distinct from any of the other species in colour.

***S. purpurea*.**—This is one of the commonest of all, and, at the same time, a handsome decorative plant, of robust habit when grown under the above conditions. Mr. Baines and other cultivators have exhibited masses of this species fully a yard across, when it is a most curious and interesting object at our floral exhibitions. Last year I saw two great pans of this in the small but select collection of Sigismund Schloss, Esq., of Bowdon, Cheshire, and these were very richly coloured. I attribute this to their being grown close to the

glass in a north house, where they obtained a full supply of light and plenty of air. This is the first plant in the whole group that an amateur should attempt to grow; and, if he succeeds with this, other rarer species may be added without much fear of failure. It is hardy in constitution, and I have seen it grow freely in a Ward case at a north window. It was potted in a wide and shallow pot, the latter being plunged up to the rim in the open peaty compost, the plant-case, and the whole being neatly surfaced with living *Sphagnum* and *Selaginella*; the requisite moisture at the root, and in the atmosphere of the case, was easily obtained by occasional sprinklings with a syringe. As before stated, this species is perfectly hardy in sheltered situations, but it does not grow so vigorously when fully exposed as when protected in a frame or cold pit. The pitchers of this plant are 4 to 8 inches in length and much swollen at the mouth, being of a reddish-purple tint when well grown.

***S. minor*.**—This is the smallest of the whole group, bearing erect pitchers 4 to 8 inches high, and seldom more than half or three quarters of an inch in diameter. They are nearly cylindrical, and dilated at the mouth, as in most of the other erect-growing species, and of a fresh green colour at the base, tinged with red or reddish-purple towards the apex. The flowers are borne on slender stalks about a foot high, and are remarkable for their small size, and dark purple, nearly black, petals. This kind has frequently been confused with *S. variolaris*, from which, however, it may be readily distinguished by its smaller size. *S. variolaris*, moreover, is a green-flowered species, and the flowers are much larger than in the present plant. It is a pretty little species, well worth culture for variety, and makes rapid growth if kept cool, moist, and airy.

***S. psittacina*.**—This is one of the most peculiar members of the genus, readily distinguished by its pitchers lying horizontally on the surface of the compost in a radiate manner, and in their having a curved hood, not unlike that of *Darlingtonia californica*, but without the fish-tail-like appendages of the last-mentioned plant. It is one of the most ornamental plants of the whole group, and should be included in every select collection. This plant should be well elevated above the rim of the pot, so that its pitchers can recline in a natural manner on the mossy compost.

***S. variolaris*.**—This is a free-growing erect plant, though not attractive as some of the others; still, where a collection is grown, this should be included to complete the group. It has flowers of an apple-green tint, and grows well treated like its congeners.

*Sarracenia*s are readily propagated by division, offsets being freely produced by well-established specimens. I have never seen seed produced in this country; but, if the flowers were fertilised, this might, in all probability, be obtained, and some fine varieties be the result, even if raising seedlings would not prove the quickest way of raising a stock. I have now *S. flava* and *S. Drummondii* in bud, and shall try the experiment of cross fertilising these as soon as their flowers are fully expanded. One of the most peculiar points about the flowers of these plants is the broad, disc-like stigma, in shape not unlike an umbrella when open. The pollen is powdery and can readily be applied to the viscid stigmatic surface by means of a moist camel's-hair pencil. G. H.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

***Regelia ciliata*.**—This pretty greenhouse plant, which belongs to the Myrtle family, is figured in the *Botanical Magazine* for this month. It is native of south-western Australia, and forms a bush 3 to 5 feet high, with more or less pubescent or hirsute twigs and leaves; the branchlets are slender, strict, and densely clothed with leaves. Flower-heads globose, half to three quarters of an inch in diameter, of a dull purplish-red colour, with numerous bundles of bright rose-coloured projecting stamens, which impart a pleasing feathery appearance. It flowers in September.

***Dicliptera (Justicia) Twediana*.**—The current number of the *Revue Horticole* contains a coloured plate and a description of this handsome greenhouse plant, the seeds of which were sent by M. Lasseaux from Montevideo, to the Muséum, at Paris. It produces a number of flower-stems from 1 foot to 2 inches high, branching trichotomously, and bearing at the ends of the branches numerous flowers, of a bright orange-red colour, and arranged in close erect whorls. At Paris, it has been planted out in the open air in summer, and continued to flower all through the autumn until the appearance of the first frost. It appears to be a most effective plant.

Variegated American Aloe.—Complaints are often made that the variegation of this plant does not colour well—a circumstance doubtless frequently owing to its being kept too moist at the roots. In the conservatory at Ealing Park are two very fine examples of this Aloe, in tubs, the variegation of which is most brilliant. Some time ago these two plants had a dull and unattractive appearance, which induced Mr. Cole, the gardener at Ealing Park, to remove them. On turning them out, it was found that the soil about the roots was cold, sticky, and retentive character. This was removed, and some light sand plentifully mingled with rubble, was used in re-tubbing the plants; on the 10th, were laid pieces of white stone. The result was quite surprising; a singular to state, water is never given to the roots. All the moisture they get what falls from the creepers overhead when the house is syringed.—R. D.

TREES ABOUT MARKET PLACES.

WHEREVER London trees are now putting forth their tender leaves of most delicate green they seem to say, "Why not more of us? You evidently enjoy the fresh cheery aspect of our foliage, so why be so chary of planting many more?" When the little town princess was taken into the country and beheld the fields and trees she asked her governess why they did not build cities in the country; as the reply of the governess is not recorded it is to be presumed she was too much puzzled by the question to be enabled to answer it, and, doubtless, changed the conversation as promptly as possible. But may we not ask a question of a somewhat opposite character—and say, "why do they not bring some of the best features of the country into the cities?" Many of our wider streets might, has been previously urged in this journal, be planted with order trees, and many open spaces be made green and pleasant by an annual supply of fresh country turf. Why "they" do not do it is one of the mysteries which no man, who is not a strict-surveyor, or a vestryman, or a common councilman, can explain. The mysterious "they," meaning, of course, nobody in particular, is, at all events, a power which has been hitherto a very successful obstructive in this matter.

diameter as likely to reach nearly a foot each in some thirty years' time, would occupy the place of twenty Cabbage-stands, which, at rentals of £10 each, would produce an income of £200 a-year, which, he might possibly say, "ought not to be muddled away for the sake of a few trees." That the assumption that the above-named actors in the matter, as material beings actually representing the mysterious and invisible "they," is altogether an imaginary one, need not be said; but, nevertheless, it is safe to assume that, by the assistance of an irresistible power of some kind or other, trees will not be permitted to put in an appearance in new Covent Garden Market.

Will the suggestion for planting trees about the New Cattle Market at Islington, and along the principal façades of the New Meat Market, be more successful? It is scarcely to be expected that it will. There is certainly ample room for their introduction at the Islington Market, and also in front of the new buildings of the Meat Market; the latter structure being so handsome, it is evident that with an appropriate *entourage* of that kind, it would form one of the most attractive objects in London. But "they" might object, and the "they" of the City of London is one of the most powerful and obstructive "theys" in the

Trees about Market Places.

When the late Mr. Loudon planted a beautiful tree in front of the house, which he built in Porchester Terrace, the mysterious "they" issued orders for it to be dug up and carted away at the planter's own expense. One not accustomed to the nature of the prompt and sweeping action of the mysterious "they," might imagine that the tree in question ought to have been accepted as a valuable hint to the effect that a whole avenue of such might be planted with pleasing effect along the entire length of the terrace; but "they" did not think so, and down it came.

The accompanying engraving represents the *Halles centrales* in Paris, round which, it will be perceived that young trees have been planted, which produce a very agreeable effect. Why, therefore, should not the projected new Covent Garden Market be enlivened by the refreshing verdure of growing trees? This is a question that it is much more easy to ask than to obtain an answer to. The mysterious "they" is a power not open to questioning of that kind; and, invariably, maintains a dignified silence. It may be that the architect would object to any of the lines of his structure being even partially concealed, from any possible point of view. It may be that his Grace's steward, if he happens to have thought about trees at all, may have calculated that the trunks of, say, forty trees, taking their average

world. It is but recently that, by the clearances effected for the line of the new Queen Victoria Street, a comparatively small triangular space was created on the western side of the Mansion House, which opened a fine view of its west front; and showed plainly how, by a little architectural modification, that side of the structure might be made to assume a very imposing aspect; and how a noble portico, beneath which carriages might be driven to set down visitors comfortably in any weather, might have been constructed, thus giving additional importance to the palace of our metropolitan magnate, the Lord Mayor. In addition to this advantage, the open space afforded an opportunity for a really handsome public fountain—a luxury and ornament which hundreds of even the petty towns on the Continent enjoy, but which London does not at present possess. The fountain might have been made the substructure of a splendid marble canopy (supported on decorative columns), beneath which suitable protection the bronze statue of the magnificent merchant, Peabody, might have been placed within a fitting shelter from rain and sleet and snow, instead of being relegated to an inconspicuous corner, with no more attempt at suitable surroundings than when in the sculptor's studio; as though it had been shot down where it is, according to contract, and there left. Round about the proposed fountain and its crowning canopied statue, there might have been a space

of green turf, enclosed within a handsome balustrade of polished red granite and white Sicilian marble, both of which materials have been found to stand our climate without sustaining any injury from the severest winters. Within this enclosure, three trees might have been planted, with plenty of room for future growth, one to the west, one to the north, and one to the south, leaving the eastern side freely open, in order to afford an unimpeded view of the statue and fountain from the Mansion House. But this utilisation of the small triangle of open ground, the freehold property of the City of London "they," the undefinable "they," decided to Let or Sell for building purposes; and the consequence is that a towering building will arise that will so far shut out "light and air" from the west side of our City Palace, that an action for deprivation of those important necessities of life, would certainly have been forthwith commenced by any private proprietor, who had not himself committed the act of selling or letting his land, with the full knowledge that his "light and air" would necessarily be shut out by his own wilful "Act and Deed." The invisible, inscrutable, and undefinable "they" of the great city, will, of course, never condescend to state why they chose to let slip such an opportunity of embellishing their central seat of honour and power, and, at the same time, of doing something like decent justice to the memory of a great benefactor. As regards the planting of the three proposed trees, however, the inscrutable power might vouchsafe, through some unexpected channel, something of an answer, to the following effect—"Why more trees? is it not written, and has it not been written, over and over again, that there is not a single street in all the city of London from some part of which a tree may not be seen?" The obvious retort to this answer, intended to be crushing, is "why not trees."

H. N. H.

THE FRUIT GARDEN.

WATERING PINES.

I HAVE long been of opinion, and I am daily becoming more convinced, that the giving of water to Pine plants, from the day they are put in as suckers until the fruit is matured, is by far the most important part of all their cultivation. Nothing is more antagonistic to the well-being of the Pine than excessive watering. No plant with which I am acquainted requires less water throughout the whole year; and no plant will exist and remain healthy for the same length of time, without water, as the Pine. I have put in suckers in September, watered them when rooted in October, and did not give them another drop for four months afterwards; and at the end of that period they were much healthier, and altogether in a much better condition than any which I have seen that were watered regularly every fortnight. The pale yellow sickly colour, which is too often observable amongst Pines is the indication of too much water at the root. In very many instances, Pine watering is done periodically, irrespective of all absorbing or evaporating agents; certain dates are put down and strictly adhered to, whether in the dull inactive winter months or in the scorching summer time. There are many considerations which must be kept in view in Pine watering; the first of these is bottom-heat—when this is strong they require water more frequently than those that are kept cool at the root. Another most particular thing to be observed is the state of the plunging material; if the tan-leaves, or whatever else may be used, are very damp when the Pines are plunged, or become damp at any time, water should be very sparingly given, and it will be found they only require it at long intervals, as the moisture they absorb through the pot is sufficient, but, under such a variety of circumstances, the times for watering cannot be given; their needs, or supposed needs, should never be judged from the last time they were watered, but from their actual requirements, which can be easily ascertained by feeling the balls with the hand. Pines, in fruit, generally require water oftener than those without it; but, even when in fruit, water should be applied with caution. When water is given, the balls should be thoroughly soaked. I fill the space between the soil and the rim of the pot two or three times when watering to ensure this. I am very much pleased to see that, in your well-written notes of "Work for the week," you recommend the withholding of water after the fruit begins to change colour. This, it will be remembered, is not in accordance with the instructions of J. S. W., at page 217, of THE GARDEN, where it is said, "if well swelled glistening fruit, with the juice almost oozing out of the pips, is desired, watering must never be discontinued, even when the fruit is quite ripe." Pines, which are watered after

colouring commences, are invariably found, when cut up, to be p decomposed in the centre, and quite black at the core; therefore care should be taken to avoid watering at this important p If Pines are well grown up to the time of colouring, water is unnecessary to promote further development, or to add more j Regarding syringing or damping overhead, this is very beneficial judiciously done in the afternoons of very hot scorching days, should never be too freely indulged in during dull sunless weather or large crowns, sometimes twice the length of the fruit, are unsightly result.

J. MUIR

ON THE CULTIVATION OF ORCHARDS.

By F. FALKENER.

THERE are three principal circumstances which appear to influence the growth of Apple trees, and to determine their natural localities, namely, climate, soil, and aspect. Though Apple trees will endure winter of greater severity than is generally experienced in any part of the British Islands, yet, to bring their fruit to maturity, require warm summer, and, therefore, the southern and western counties are more favourable to orchards than those of the north and east, and accordingly they are more generally cultivated in the former than the latter, even where the soils are of a similar character. Great light has been lately thrown upon the adaptation of soils to particular plants; and it is now easy to account for the predilection, to speak, of the Apple tree for soils that abound in clays and marls. All deciduous trees require a considerable portion of potash for the elaboration of their juices in the leaves, and are prosperous or otherwise in proportion to the plentiful or scanty supply of that substance in the soil. Liebig has shown that the acids generated in plants are always in union with alkaline or earthy bases, and cannot be produced without their presence.* The most striking exemplification of this necessity is the Vine, the leaves, tendrils, and unripe fruit which are remarkable for their acidity. It has been proved that Vineyards supplied with manure of a very forcing kind, but which contains no potash (horn-shavings, for instance), soon cease to be productive. Now the Apple tree, during its development, produces a great quantity of acid; and, therefore, in a corresponding degree requires alkaline, and probably earthy bases also, as an indispensable condition to the existence of the fruit. Without such substance, therefore, in the soil, in adequate abundance, orchards cannot prosper; and it is morally certain that more accurate inquiry and observation will establish the fact, that, all other things being equal, they are productive or otherwise in proportion to the quantity, up to a certain limit, of these substances in the soil. It is known that clays contain potash, and that marls consist of clay and carbonate of lime, and also contain potash, besides sulphate and phosphate of lime. The presence of alkaline and earthy bases, particularly potash and lime, affords a satisfactory solution of the adaptation of marl soils to the production of Apples, even without taking into account the part which phosphate and sulphate of lime play in their formation. These considerations are very interesting, as they are calculated to throw a valuable light upon an important branch of horticulture and rural economy, by pointing out the means of exercising an effectual influence upon soils in the production of Apples which are not naturally adapted to that purpose. Nor is the opinion above entertained mere speculation, for we have almost everywhere sufficient proof that soils not naturally adapted to the growth of Apples are, by the application of manure, made to produce them in great plenty and perfection. It cannot be denied that the ammonia, and also the humus of the decaying dung, must have some influence upon the growth of the tree in such soils, and also on the development of the fruit;† but it is, at the same time, most certain that these alone would be perfectly inefficient for the production of the fruit without the co-operation of those bases which the manure also supplies, and which are naturally deficient in such soils as we are now speaking of. The size, and perhaps the flavour, of the fruit may be somewhat affected by the organic part of the manure, but its very existence depends upon the presence in the soil of a sufficient quantity of those inorganic or mineral substances which are indispensable to the formation of the acids. If further proof be wanting of the effect of potash upon the productiveness of fruit-bearing trees, it is to be found in the benefit derived from manuring Apple trees with leaf-mould which contain it in considerable quantity. This effect is remarkably exemplified in the application of the cuttings of Vines to their roots, by which practice Vineyards are kept in full bearing for any number of years, without any other manure, and of which Professor Liebig, in his admirable work on agricultural chemistry, has cited two remarkable instances. With these views, it is reasonable to refer to

* "Chemistry of Agriculture and Physiology," p. 92.

† It is not probable that trees with large systems of leaves can be made indebted to the soil for those organic substances which the atmosphere abundantly supplies.

more general cultivation and prevalence of orchards in the districts above named than in any other, principally to the greater abundance of that mineral food so essential to fruit-bearing trees, producing a large quantity of acid. We shall have occasion to revert to this subject in treating of the manuring of orchards. With regard to the best districts are favourable to orchards which have more or less undulating surface (and, therefore, present numerous localities where sheltered and, at the same time, sunny aspects are favourable to the setting and ripening of the fruit), and often acclivities, which, though of excellent soil, are too steep either for cultivation or for the pasture of heavy cattle. Very open or elevated and exposed situations, and the bottoms of deep-sunk valleys, are almost equally unfavourable: the first, from the violence of winds and low temperature, and the latter, from their liability to cold fogs and late frosts while the trees are in blossom, which often, in one fatal night, utterly destroy the hopes of the husbandman. In planting an orchard, therefore, the site should not be chosen "in lowly vale fast by a river's side," nor, on the contrary, at an elevation too much exposed, but on moderately sheltered southern slopes, and, when choice will either permit, inclining rather to the east than to the west; for, though a slope inclined to the south-west is warmer than one to the north-east, it generally retains the fogs longer, and, therefore, is more dangerous to the fruit in the spring of the year. A situation which is surrounded, or closely hemmed in by woods or plantations, is almost equally as objectionable as a close watery bottom, as woods exhale a vast quantity of moisture from their leaves, and the fogs produced over them dissipate much more slowly than those over open ground.

Raising Plants.

Apple trees are generally purchased from nurserymen, or persons who make a particular business of raising them, and who sell them at prices varying from 2s. to 5s., according to size and quality. They may, however, be raised with great facility by any intelligent cultivator; and where orchards are much cultivated, considerable profit might be made by selling them to others. At all events, a few young trees should be always coming forward in the provident cultivator's garden, for the purpose of filling up vacancies occasioned by accident or decay. It is a prevailing opinion that the hardiest and best stocks are those which are raised from the seeds of the wild Apple or Crab; and Mr. Knight recommends that the pips should be taken from the fruit as soon as it is pressed, but the pommey (that is, the pulp after it has been pressed) will generally contain a great number of entire seeds. These pommey, or that from the Apples of healthy and vigorous trees, should be thickly laid and covered up in shallow trenches, about 18 inches apart, so as to admit of the young plants being well hoed and weeded in the following summer. Immediately after the fall of the leaf in the ensuing autumn, the strongest plants might be drawn, and planted 18 inches apart in rows of the same distance from each other. The land should have been previously trenched, manured, and cultivated for garden produce. The remainder should be similarly managed in the following year. During their future growth, the ground should be kept perfectly clean by repeated hoeings; and the plants would be much benefited by a light forking between the rows. A knife should be allowed to approach them in this stage, unless it is so short as a rampant-growing shoot, which may be making too long a diversion from the stem, and not even then if it be more than a foot from the ground, at least when it is intended to graft the plant; for every twig and leaf contributes to the growth of the root and the stem, the only thing, at present, to be regarded. When the plants are more than half-an-inch in diameter, at a foot from the ground, or about two or three years' old, the head should be removed, and the stock grafted about 10 inches from the surface; and, at the same time, every sprig and bud of the stock should be carefully cut off, in order that the sap may be more vigorously determined towards the graft. The mode of grafting will be noted presently. When the graft has grown about 2 feet in height, the plants should be removed or planted out in land similarly prepared, in rows 4 feet apart, with an equal interval between each plant, where they are to remain until finally removed to the orchard. Before the plants are removed from the grafting-site, no side-shoots should be cut off, except those below the graft. On their removal to open rows, any overgrown branch may be shortened, and two or three of the lowest removed close to the stem. After this, the stronger side-shoots only should be moderately shortened, in order to encourage the upright growth until a good head is formed about 6 or 7 feet from the ground. The side-shoots may then be removed, close to the stem, in two successive years, while the head is left to its unrestricted growth. It is very common, and bad practice to cut off all the side-shoots early, leaving only two or three twigs at the top, by which means the plant is very much checked in its growth, and, instead of producing a firm tapering stem, it becomes almost cylindrical, and tortuous, instead of upright. Those who treat plants in this way are, undoubtedly,

ignorant of the true nature of their growth, and the important office of leaves; and, therefore, in attempting to assist Nature in her operations. If such persons had equal facility of witnessing the growth of the roots, they would, no doubt, think it their duty to cut part of them away, with a view of promoting the growth of the stem—at least such a proceeding would be not less absurd. Every leaf is a feeder of the plant, no less than every rootlet; and no interference with the progress of the plant should be allowed, except for the purpose of preventing any side-branch becoming a rival to the head. When, however, the plant has attained the required height of stem, and the head has pushed forward strong shoots above that height, the whole of those on the stem may be finally cut away as before directed, the stem having by this time gained sufficient substance and strength to preserve its erect position, and to support the head. Apple trees are generally fit for planting out in the orchard at about seven years of age, at which time, if they have been well treated in the nursery, they will be about an inch and a half in diameter at the middle of the stem. The particular age, however, at which trees should be removed to their final destination, after they have formed a good head, is not very important, provided they do not very much exceed the above size; and the objection to a greater size is the difficulty of taking them up with a due proportion of roots, so as to prevent them receiving too great a check. It must be obvious from analogy that early transplanting is preferable to late, provided the trees be well and substantially fenced against injury from live stock of every kind—that is, with posts and rails, and with thorns immediately surrounding the body of the tree. The habit of keeping the trees in the nursery until they are what are called strong trees, can have arisen only from the feeble fencing they too generally receive by which the tree is often made the chief support of the protecting Thorns or Furze.

Selection of the Best Kinds.

The subject of grafting necessarily involves that of the selection of sorts. The best fruit, whether for cider-press or the table, are frequently not the most productive. Every individual seed produces a new variety, differing, more or less, from the parent tree; and all the best varieties we possess are derived from one common parent (the native Crab), and owe their excellence to selection and cultivation, in like manner as the most polished society of the present day is derived from a race originally rude and savage. Each particular variety of Apple has its period of vigour and decline, and its duration cannot be protracted by grafting beyond a certain limit; and it is very remarkable that within that natural limit, the grafts partake both of the vigour and the decrepitude of the parent tree or variety. The period of duration is not known with any precision, and, perhaps, is longer in some varieties than in others. It is generally supposed, however, that it never much exceeds two centuries. Mr. Knight, one of the most profound physiologists of this, or any other country, has observed that the disease called canker is always the consequence of grafting trees from very old sorts, and which are in their declining age; and that though the graft will often grow vigorously at first, it soon begins to exhibit symptoms of disease, which no management can avert. It seems probable that even the power of growing at all cannot be extended beyond the limit, barring accidents, which Nature has assigned to the existence of the original parent or patriarch of the family. Many kinds, once very celebrated, have long since disappeared from the catalogues of gardeners, and can now nowhere be found; while many other varieties, which were much esteemed in their palmy days of bearing, are fast approaching to extinction, and, at the present time, present only a few scattered and dwindling specimens, amongst which we regret to number the celebrated Cockagee cider Apple and some excellent Pippins. By the industry of horticulturists, however, a great number of new varieties of excellent quality have been raised to supply the place of those we have lost and are losing, in which there is more merit than would, at first thought, be supposed; for a good sort out of the number of seedlings raised is like a prize in a lottery, and it must be remembered that some years must elapse before the experimenter can draw his prize, if, indeed, there be one for him. Mr. Knight has been one of the greatest experimenters in this way, and has raised many good varieties. In the purchase of young trees or in grafting, in order to form a productive and profitable orchard, care must be taken to select good sorts, which are either new, or in the vigour of their bearing, whether for the cider-mill, the table, or the kitchen. Apples for these several purposes recommend themselves to our choice by very different qualities, though some few are almost equally well adapted to all purposes. In those for the table we require sweetness, with a subdued and pleasant acidity, and a delicate aromatic flavour. In the kitchen Apple, size, the quality of keeping, and considerable acidity, are the principal requisites; acidity is indispensable in Apples intended for boiling and making sauce. The best fruit for cider are those which yield the heaviest juice; and these are not,

generally speaking, agreeable to the palate. The celebrated Cockagee Apple is absolutely uneatable, though it is very fragrant and inviting to the eye. I was once told by a cultivator that he offered a boy a shilling if he would eat one in his presence. The attempt was made, but was soon abandoned, from the impossibility of getting it down. The red and yellow colour of the rind is considered, by cultivators in the Apple districts, as good indications of cider-fruit, and Apples of the various degrees of those colours are decidedly preferred to those of which the rind is green. Knight observes that those Apples only which are of a yellow colour, or a mixture of yellow and red, are proper for making the finest kind of cider; but the quality of all cider is very much influenced by the different processes practised in its manufacture, which will be treated of in due course. In order to ensure the obtaining the most desirable sorts by means of grafts, the orchard from which they are intended to be taken should be carefully inspected in the previous autumn, just as the fruit is arriving at perfection, and the proper trees marked. The grafts, which should be taken off in February, should be of the last year's shoot, and taken from the strong lateral branches of free and vigorous growth. The ends may be cut off, and the part reserved should be about 8 or 10 inches long. They should be kept covered up in dry earth until the middle of March, which is generally the best time for grafting, as the sap then begins to rise freely, and affords a better chance of a successful operation. The immediate object of this operation is to bring the bark and young wood, both of the stock and scion, into close and permanent contact, by which means the vessels of the one are enabled to communicate with those of the other. This is effected by several different methods, which have their various denominations; but that which appears to be most generally approved, in grafting young Apple stocks, is what is called saddle-grafting, as affording the best means of bringing into contact a larger surface both of the bark and wood, and thereby giving a better chance of success, and also of preserving the graft firmly in its place. Grafting upon old stocks and large trees is performed by the method called cleft-grafting. These operations, however, require great nicety, and are generally performed by professional gardeners; and, as they can be learned by inspection and practice only, it is needless to describe them here. The principle is the same in all cases, namely, to bring a clean recent oblique cut of the corresponding parts together, as mentioned above. They are then firmly fixed by a ligature of bast or garden-matting, and preserved from the air by a thick covering of a compound of clay, horse-dung, and chopped hay, previously well blended together. If the trees are to be purchased from a nursery, ready grafted, and the sorts cannot be relied upon, they should be inspected in the previous summer while in leaf; and those selected which give the greatest promise of making good and healthy trees, and the most likely to be good bearers. They should have full and flourishing heads, and broad roundish leaves, as such generally bear the largest fruit and the most abundant crop. In winter such trees will present a larger and fuller bud than those whose leaves are small and pointed; but, though these are favourable indications of the size of the fruit, and the productiveness of the tree, they are by no means so with regard to other qualities, as the trees may be early or late bearers, and the fruit red, yellow, or green; and whether they will produce either good cider Apples, or those better adapted to the table, can only be known when they produce their first fruit. If they then prove not such as are desired, or there is too great a proportion of one sort, grafting in the head should be had recourse to. This will, it is true, protract the time of bearing a year or two; but it is much better to submit to two, or even three, years' delay, than for a hundred years to have bad fruit.

Pears.

The Pear tree will grow, and produce great crops of fruit, on soils which are not favourable to Apple trees. For instance, on drier and lighter soils, consisting chiefly of sand. In Worcestershire, Herefordshire, and Gloucestershire, they are often planted in hedgerows; and from such trees the farmer frequently derives a large supply of excellent perry. The trees of the perry Pear are, some of them, so large that one will, in very favourable seasons, produce several hogs-heads. There are, however, some objections to the practice of planting fruit trees in hedgerows; they shade the land, are exposed to depredation, and require the exclusion of cattle during a considerable portion of the autumn. But we ought to set against these objections two countervailing advantages; the ditches of a field receive a great deal of nourishing matter from the drainage of the land, which readily finds its way to the roots of the trees; and the sun has freer access to the trees so situated than when they are crowded together in orchards. Pears trees are but little cultivated in the counties of Somerset and Devon, at least for the making of perry, which is the more remarkable as the soils of both counties must be equally favourable to their growth; but as the Pear tree is many years before it

comes into bearing, this neglect may have arisen from the nature of the tenures. A tree which requires twenty years to bring it into bearing should be planted by the person who is in possession of the fee of the land, or it is not likely to be planted at all. The best perry trees are generally very harsh and disagreeable to the taste, and, indeed, may be considered uneatable, so that even hogs are said to refuse them; and yet they produce, when ground, very sweet pulp and juice. The sweet eating Pears make a much inferior perry, which soon turns sour. The mode of raising Pear trees is precisely similar to that of Apples. Stocks may either be raised from the wild pear, or from the seed contained in the pulp after making perry; but there is so much reason to prefer the wild kind to the perry kind, that the Crab-stock to that raised from the Apple seed. A repetition of the process is, therefore, needless, and particularly as they are generally purchased from the nurserymen, to whose department the business of rearing more properly belongs, and by whom it can be better executed. It may be observed, however, that the Pears will succeed if grafted upon the Apple, Service, Medlar, or Quince stocks. Some Pears are said to be improved by being grafted upon the latter, but the hard sorts are rendered gritty. The kinds of Pears cultivated in the counties of Hereford, Worcester, and Gloucester for perry making, are, principally, the Longland, the Square, the Oldfield, the Barland, the Sach Pear, and the Red Pear. Before we quit the subject of rearing plants, it may be well to observe that it is a common practice, after the plants have been removed to wide rows, to cover the interval thickly with litter, when it is readily obtainable, which prevents the growth of weeds, keeps the ground moist, and, as it decays, yields manure to the plants. It would, perhaps, be a better practice to raise two or three successive crops of manured Potatoes.

Planting Out.

When the trees have shed their leaves is the most proper time for planting out. They should be taken up with their lateral roots at least 2 feet in length, and planted as soon after as possible. In planting orchards, the ground, for the space of at least 6 feet in diameter, should be trenched to the depth of 16 or 18 inches, and well broken by the spade or mattock, the turf being thrown to one side. It is of some importance that the tree, when planted, should stand in the same position, with regard to the points of the compass, as that in which it grew in the nursery; in order to ensure this, the south or north side of the trees should be marked before they are removed from the nursery, and this may be done when trees are purchased at the time of selection. The roots should be taken to surround the roots with the finest part of the soil, and to plant the trees at precisely the same depth as they stood in the nursery. The ragged or lacerated ends of the roots should be taken off with the knife; and the hole, after being prepared as above, opened wide enough to admit the longest of the roots. If the ground at the time of planting be dry, and water can be conveniently procured, two or three bucketsful, applied to each tree, will be of essential service in securing its growth. The tree being placed in the hole, and temporarily fixed in its position by a single stake, the hole should be nearly filled with soil, and the water poured upon it. After a few hours, the remaining mould may be added, and well trodden down. The ground of fencing must be suited to the kind of stock kept in the orchard. If sheep only are depastured, the tree should be closely surrounded by strong thorns stuck into the ground, enclosed and sustained by thick stakes driven into the firm ground beneath, and reaching nearly to the forks of the tree, and these firmly held together by strong bands or withes. As a further precaution against damage from the gnawing of sheep at any exposed place, the trees should be washed or smeared with a mixture of creamy lime and cow-dung, which should be renewed from time to time as occasion may require. If it be indispensable to stock the orchard occasionally with cattle, the tree must be fenced by two or three rough strong poles fixed firmly in the ground, and united by strong battens or rails nailed to each, and embracing thorns or furze closely rounding the tree. It is a miserable economy to perform this part of the business of planting imperfectly or scantily, as many orchards have been ruined by the neglect of proper and substantial fencing. In some situations, where flat slaty stones abound, the trees are sometimes surrounded by a circular wall. The trees should be planted at the distance of from 40 to 60 feet apart, according to the richness of the soil; for it should be always remembered that the roots extend far beyond the branches. At 42 feet distance, twenty trees will stand upon an acre, which may be generally considered the proper number. The rows should run north and south, in order that the trees may derive the greatest benefit from the sun. In the ensuing spring, a thick dressing of a well-mixed compost of manure and earth be laid over the whole space that has been opened

trees, and afterwards dug in, it will be highly beneficial to them; digging or forking round the trees should be repeated every year, for three or four years. If the ground be wet it should be thoroughly drained by deep covered trenches between each row of trees; and if, besides this, the whole ground were trench-dug, and the turf replaced as the work proceeds, if Grass-land or trench-dug if arable, the expense would be well repaid by the rapid growth of the trees, and the improvement of the land.

Best Soils for Apple Trees.

It has been observed before that the extensive culture of Apple trees is chiefly confined to certain districts, which abound with rich and heavy calcareous soils; and the probable and principal cause of this partial distribution has also been noticed, namely, that such soils contain, in greater abundance, those mineral substances which are essential to the growth of the tree, and more especially to the formation of the juices of the fruit. It has likewise been observed that the natural impediments in other soils to the successful cultivation of the Apple are removed by a liberal supply of ordinary manure, particularly the fallen leaves of trees, in all of which potash is very abundant. The soil of the London clay, though not naturally favourable to the growth of Apples, is, by trenching and manuring, able to produce not only plentiful crops of Apples, but also all other juicy fruits in great abundance and perfection; and this triumph of cultivation over the impediments of nature is manifested to the highest degree in the extensive gardens that surround and embellish the Metropolis. The extensive system of leaves of all fruit-bearing trees is probably quite adequate to the supply of all the organic or gaseous substances which both the tree and the fruit require, and, therefore, it is in the mechanical state and to the organic constitution of the soil that we must look for those conditions which are either favourable or unfavourable to the growth and productiveness of such trees. It is not enough that the soil be neither too open nor too retentive for the supply of the due degree of moisture; it must also contain those inorganic or mineral substances which the tree and the fruit require. When the defects are obvious, the remedies are obvious. By draining and trenching only, the soil may probably be rendered favourable to the production of Apples; and, if this mechanical operation (at all times beneficial in arable soils) fails to produce the desired effect, it is evident that other manures are wanting, which may be supplied by heavy dressings of lime or peat-ashes, or both. If the soil be too porous, a heavy dressing of marl is the best remedy; and, when this cannot be procured, clay, with lime and peat or other ashes, will supply its place. There are but few situations, however, where it would be proper, except on a very small scale, to render light those lands which are capable of bearing Apples. It has been observed, that marls, besides being rich in lime, contain also potash and sulphate and phosphate of lime. Lime and peat-ashes generally contain more or less of the same substances, and, in applying them to soils which do not contain them, or in which they are defective in quantity, we only supply the deficiency of Nature. Every cultivator knows that no soil can be productive without a plentiful supply of water; but those principles or substances which water conveys to plants, and which are equally essential to their existence, have hitherto, for the most part, been as separate substances, escaped his observation, obscured, as it were, in the general mass of manures which he conveys to his plants. The fertilising effect of certain salts, which constitute only a small part of this manure, and which, till lately, were never thought of as forming a necessary part of the food of plants, has awakened that spirit of inquiry which promises to lead, at no distant time, to a knowledge not only to the cause of the fertility and barrenness of soils, generally speaking, but also to a more exact knowledge of the peculiar adaptation of certain soils to particular plants; in other words, the true reason why any particular plant will thrive in one soil and not in another. That most ingenious and thoroughly practical people, the Chinese, have long since experimentally discovered the means of adapting their soils to the plants they wish to cultivate, and provide the proper manure for each particular plant. We have much, therefore, to learn in this particular, at least, from the Chinese, whom we have been accustomed to regard as semi-barbarians. Indeed, in some respects they are. Science has recently opened to Europeans a shorter and surer way of gaining knowledge of this, and at least affords them a guiding light by which to conduct their experiments, in the exact analyses which may now be obtained of soils, and of the soils upon which they grow and prosper. The observations upon the artificial adaptation of the soils to the growth of Apple trees are merely thrown out as suggestions. The young trees have been carefully planted and well-fenced, and will require but little attention, except that of keeping the fences and taking care that they be not shaken by the wind. As regards the latter, the tree should be well armed with

a firm bandage of straw at the part where it rises above the top rail, and there confined between two cross-pieces, passing from one rail to the other, or else so firmly fixed by withes-bands as effectually to prevent any rubbing, and consequent injury to the bark.

Pruning.

The bearing capabilities of Apple trees of considerable age may be much improved by judicious pruning, in removing decayed branches and old unprofitable boughs, where the head is much crowded. These should, in all cases, be taken off by a clean cut close to the branch from which they are separated, or, at least, to a lateral shoot, so that the part may heal over as soon as possible. By pursuing such a course of pruning, and by keeping the body of the tree only just sufficiently open to permit the sun to penetrate, the weight of the fruit will be increased, and it will, at the same time, ripen more regularly. Mr. Knight recommends most attention to be paid to the lateral branches, which, if unchecked by occasional pruning, are apt to load the tree too much at the extremities. In damp situations trees are often covered with Moss, and thievish Mistletoe takes root in their branches, and robs them of their juices. These parasitical ornaments should be perseveringly removed from the trees, though they are often suffered to grow with their growth, and strengthen with their strength; or, it might be more properly said, at the expense of their growth and strength. Sometimes trees, which at first were good bearers, become stag-headed and unfruitful. It is more than probable that this condition is owing to some defect in the soil. The proper remedy to be resorted to in this case is what is called heading-down—that is removing all the branches to within a foot or two of the main forks or the stem of the tree, in order to encourage the formation of a healthy and vigorous head. This operation should be accompanied with a heavy dressing of compost, formed of lime, ashes, and earth, extending for a considerable distance round the tree, which should be dug in with the marled turf. If the land be wet, draining must be resorted to, as in that case other trees are, no doubt, suffering in some degree from the same cause. If the tree be infected with canker, the same treatment should be adopted; but in this case there is but little hope of success, for, according to Knight, that disease is symptomatic of the declining age of the species, which no treatment can effectually cure, except in the case of trees which have been grafted in the head. Fresh grafting, if the stocks be young, will remedy the evil. In otherwise hopeless cases, such treatment of stunted trees is deserving of trial; for, if it succeed, a large and full-bearing tree is soon obtained; whereas, if it be removed and a young tree planted in its place—even if it succeeds, which would be doubtful—it would be a long time before it came into bearing. When the fences are no longer deemed necessary for the support and protection of the young trees, it is still proper to guard against the injury from cattle, by smearing the stems with lime and cow-dung.

Apple Trees in Arable Land.

In Herefordshire it is very common to plant Apple trees in arable land—a practice, the policy of which is very doubtful; though there can be no doubt that the trees must derive great benefit from the tillage and manuring of the land. I am not aware that any comparison has been made between the profits of an orchard under tillage and another in pasture, on the same kind of land. Indeed, it is hardly likely that any trial of the kind has ever been instituted, or could be with any chance of a satisfactory result. It is highly probable, however, that many soils which are not naturally adapted to the growth of Apples are rendered productive of them by means of the tillage and appliances which corn-crops require, and especially by the application of lime. Trees will grow luxuriantly on certain soils without bearing Apples; on the deep gravels of the grauwacké slate, for instance. On such a soil I have seen an orchard planted upon pasture, the trees of which thrived well, but produced no fruit. There can be but little doubt that this orchard would have produced Apples under an ordinary course of tillage and manuring. It cannot be for want of humus that such orchards are unproductive, for that accumulates in Grass-growing orchards; not can it be owing to a deficiency of either carbon or ammonia, or the elements of water, for, of these, the atmosphere affords an inexhaustible supply to plants which have large volumes of leaves and extensive roots for their absorption, and this supply is renewed by every breath of wind and every shower of rain. It must, therefore, be owing to a deficiency of mineral substances in the soil, which, perhaps, the ordinary manuring and liming bestowed upon arable land would have supplied; for the constant barrenness of an orchard cannot be attributed to the effect of spring frosts. Other fruit trees, besides Apples and Pears, may find a suitable place in an orchard such as has been described. Plums and Cherries may find a place on its southern side; and Walnuts and Spanish Chestnuts serve as a protection to the north and east.

Cherries and Plums are far less choice than Apples, as to the soil upon which they grow. Productive orchards of the former are found upon the new red sandstone of Worcestershire, as well as upon the slate rubble of the valleys of Devonshire and Cornwall. In the vicinity of, or at a moderate distance from, large towns the produce of such trees often sells for a large sum of money.

Management of Store Fruit.

Apples and Pears, which are intended for keeping, should be hand-gathered when they are as ripe as they will hang on the tree. If they are taken much earlier they will shrivel, notwithstanding all the pains that may afterwards be taken to preserve their plumpness. The gathering should be conducted with great care, so as to prevent bruising, as the least injury of that kind produces decay and rottenness in the injured Apple, which soon communicates it to others. The fruit should be gathered in dry weather, and spread out singly in an open apartment for about a week, and then carefully put away in a tolerably airy place. If it be desired to keep them very long, and in high perfection, before being stored they should be carefully wiped, and each wrapped in thin paper, like that used for Oranges. Recesses, fitted with shelves so as to prevent their pressing too heavily, are the best adapted for their storage. By the latter means, Apples and Pears of the keeping kinds may be preserved quite fresh and plump until the return of fruit in the following summer.—*Journal of the Royal Agricultural Society.*

THE HOUSEHOLD.

IMPROVED COOKING APPARATUS.

MRS. A. LEWIS has delivered a lecture, at the Inventors' Institute, on improved cooking and heating apparatus, and offered some suggestions for food reform. The chair was occupied by Dr. Hardwicke. Mrs. Lewis went through all the mysteries of cooking a working-man's dinner. The stove she used was of a larger size than those with which she prepared a meal in public some time ago, but it nevertheless proved as efficient as one could possibly desire. The principle upon which her new receptacle for holding fuel is based is that of the brazier, one of the simplest, and, at the same time, most efficacious that has perhaps ever been adopted. Her description of a brazier is, by a simple mechanical contrivance, made to turn upon a pivot, the object of which is to regulate the draft, and consequently the expenditure of fuel. A "roaring" fire may be obtained by this means; or the coal or peat which is used—for it will burn either—can be reduced almost to a spark—a great desideratum, not only in warm weather for the well-to-do; but one which will, no doubt, be highly prized by the poor on account of the saving thereby attained. The remarkable thing about Mrs. Lewis's system is, that she does not allow any portion of the food, whether animal or vegetable, to be immersed in water, except in the form of steam, and in order to do this she has several very ingeniously, but at the same time very simply, constructed vessels. Another thing worthy of commendation is the rapidity with which the aqueous element is converted into what one of our cousins across the Atlantic called a state of "perspiration." From the time the match was applied to the fuel not more than three minutes elapsed before the kettle was "singing," and after two more had passed the pot, or rather cylinder, was boiling. This cylinder was about 2 feet high and something like a foot in diameter, and the interior of this vessel is fitted with shelves, the object of which is to support a description of tin colander, and these in turn hold the various vegetables. Three of these apparatuses were placed over the others in the steamer, the first containing a Cauliflower, the next some Potatoes, and the third Turnips. Then, again, in a second pan were placed some fish, all of which turned out admirably, under the superintendence of the distinguished chef. The Cauliflower was beautifully white and the Potatoes were like "balls of flower," but the most delicious of all were the Turnips. These latter, by the mode in which they were treated, were neither watery or spongy, but firm, and what is more important retained all their saccharine matter. It may be a fact worthy of note that the whole cost of keeping a coal fire going in one of these patent stoves from seven in the morning until eleven at night costs but 2½d. This fact alone ought to be sufficient, even if there were no other advantages to be obtained by them, to ensure their success. Mrs. Lewis commenced by deploring the dense ignorance of the working classes respecting all matters connected with cooking. What they wanted was cheaper food and less expensive means of preparing it than they possessed at present. She then went on to say that her stoves were not intended for the rich, although they might be made as ornamental as any, but

they were for the working classes, and especially for the labourer. The stoves were adapted for either peat or coal, either of which would burn equally well; but for cheapness and cleanliness she much preferred the former description of fuel. By using that particular sort of stove the room was warmed equally in all parts—a most essential thing to health—and persons were not frozen upon one side and scorched upon the other. Another, among many advantages which it possessed was that it emitted no smoke. People now put their vegetables, their meats, and their fish into water, and boiled or stewed them until most of the nutritive portions of them had been absorbed in that element. The same thing might be said with regard to roasting and baking. These processes were equally deleterious for they only hardened the meat and destroyed its juices. The ordinary mode of cooking properly so as to obtain every particle of nourishment the various edibles contained was either by steaming or allowing the live flame in a covered pan to get near them. What was required in order to bring about a better state of things was for the School Board to take the question up theoretically, and for the other body practically. There was no good trying to cook properly without theory. Food and condiments from abroad she strongly recommended her face against, especially for ladies, as their use produced in many instances the number of pale faces they exhibited. Soup, too, taken before dinner was a barbarism that no enlightened person should be guilty of. In conclusion, she said that she had not so much to say with the higher classes as with the poor, although she had much to say to them. What she wanted to see was the working man's home made what it ought to be, comfortable, and she could assure them at present that once such a stove as the one she had used that evening was introduced into a man's home, it became quite a different dwelling.

The Rose Harvest in Turkey.—The Adrianople Rose crop for 1873 is reported to have been on the whole a good one, and, consequently, the manufacture of attar of roses, for which this district is so celebrated, has been fairly remunerative. Distillation, however, owing to the excessively wet weather, being impeded, the produce was not of the best quality. About 938,000 oz. was the result, and the price, which, of course, varies with the quality, ranges from 13s. 1d. to 16s. 10d. per oz., the whole is valued at about £700,000. The German merchants are the principal customers for this article of luxury, and annually purchase over 60,000 oz., the remainder generally going to the Eastern markets.

Vanilla Flavour obtained from Fir Trees.—There is, it appears, in the juice of Fir trees, between the wood and the bark, a crystalline substance called coniferin, a glucoside, as chemists call it, which, when acted upon by oxydising agencies, is easily converted into vanillin, the chemical principle of vanilla. As a few grains of this vanillin will flavour at least a dozen ice puddings, and the juice of an ordinary sized Fir tree contains enough coniferin to make five guineas' worth of vanillin, it is evident that Scotland can supply all our pastry cooks with this article without greatly diminishing the forests. Fir now about to clothe her hills with the most delicate of verdant green.

Cucumber Pickles.—Many complain that they cannot pickle Cucumbers successfully. As I have preserved several barrels, perhaps I can assist others by furnishing them with my way. It is best to pick them every day. In picking them, they should not be pulled off, but the stems should be cut about half-way between the Cucumbers and the main stalk. Be careful not to cut or bruise the Cucumbers, and, in washing them, rinse them carefully, rubbing them as little as possible. Do not rub off any more of the little black prickles than you can help, for, whatever causes the juice to run makes them incline to rot. Now put a layer of salt on the bottom of your barrel or jar, on this lay smoothly a layer of Cucumbers, and sprinkle on salt enough to cover them; then more Cucumbers, and so on. As soon as the salt melts into brine, which will be in a few days, the scum will begin to rise on it. Wherever this scum touches the pickle it causes it to rot; to prevent this, cover them with a cloth the size of the barrel, keeping it weighted down with stones. Every day, when you fill up with fresh Cucumbers, take off the cloth, and rinse the scum off from it in clear water. After your barrel is full the cloth will need to be rinsed once in two or three days for several weeks. If you find scum on any of the pickles, rinse them too; and if any of them are soft on one side, throw them away. Be sure the cloth covers the pickles, and that it is kept under the surface of the brine. When wanted for use, soak them several days in cold slightly warm water, changing the water once or twice a day. Then place them in a pan of water on the stove, and let them remain near the boiling point, but not quite boiling, for half a day. This makes them softer and more wholesome than when left without scalding. They are then ready for the vinegar.—*Hearth and Home.*

HINTS FOR AMATEURS.

THOSE who are fortunate enough to possess a little patch of garden in any suburban district should now be busy, morning and evening, sowing or planting. One of the most frequent of all questions asked by amateurs is, "How deep shall I sow my seed?" To this question we can only reply that it depends on the kind of seeds sown. The amateur must be guided, to some extent, by the size of his seeds; for example, Sunflowers, Sweet Peas, Convolvulus, and Nasturtiums, have large seeds, and these will find their way through nearly any depth of soil; but the best depth to sow these is, say, an inch to an inch-and-a-half deep. Now if we were to bury some of the smaller and more tender of flower-seeds an inch under the soil we should never see the young plants come through the surface, and it is possible that the seedsman would be blamed for supplying bad seeds, when in reality the fault was our own. All small dust-like seeds should be sown on the surface of finely raked ground, and then just enough finely-pulverised soil should be sprinkled over to cover them completely. Many seeds, as Mignonette, Larkspurs, Wall-flowers, and many annuals will grow well if simply thrown over the surface of newly-dug earth and then raked in with a small-toothed rake. The object in covering the seeds is two-fold, viz., to keep them moist and dark until germination takes place, and to hide them from the birds. Everywhere in Nature we see the seeds sown as soon as they are ripe, and the falling leaves cover them over and eventually supply the young plants with the best of all manure. For the generality of large seed half-an-inch deep is quite enough, and this depth is best for all except the smallest or dust-like seeds. If the flower garden and borders are to be gay with a variety of hardy annuals, now is the best time to sow them, and not a day must be lost. A dozen showy varieties will only cost a shilling, and these will add much interest to any little suburban or town garden, however small. Now it is, unfortunately, but too true that there are many amateurs who do not know the names of half the plants they admire in the market, or in the gardens of their neighbours, so we will just name a selection of plants which will bloom during the present summer if sown at the present time, and carefully watered every evening in dry weather. This latter operation will be an interesting one, as it will bring the amateur into close communion with his plants, and in this manner much will be learned as to their individual peculiarities and requirements. A garden is of little use to its possessor unless he takes a personal interest in its management, and in time this attention will grow into a pleasure, and no part of the day will be more pleasantly spent than an hour of two in the cool of the evening when, with a cigar in one hand and a watering-can in the other, the pet plants are duly attended to. One of the easiest of all plants to grow, and one of the most deliciously-fragrant of all plants, is the common Mignonette or "Little Darling," a name bestowed on it when first introduced into French gardens. We should like to see every bare inch of soil in all our parks, squares, and gardens covered with this "fragrant weed," and one way of obtaining this is to buy an ounce or two of seed at the cost of a few halfpence. This should be emptied into one of your pockets, and then, on passing any bare spot, a pinch of the seed might be sprinkled over it, and some are almost sure to grow, and they will perfume the evening air with their refreshing fragrance. Most people like flowers, but they neglect their culture for the want of definite information how to proceed. Sweet Peas are showy and fragrant, their flowers being borne on long slender stalks makes them suitable for cut flowers, and they, moreover, last remarkably well in water. Convolvulus major, or "Morning Glory," is a handsome and quick-growing climber, and a few seeds of this should be pricked in close to any bare wall or fence, as it makes an excellent trellis-plant, or it can be trained up strings beside the door or window—positions in which its rich ruby, or purple-tinted, flowers show to the best advantage. The common Canary Creeper is a general favourite, and grows well treated like the last. It has fresh green leaves, divided into about five lobes, its flowers being of a bright golden-yellow colour, not unlike little canary birds; hence its popular name. Growing up a string by the cottage porch, or scrambling over a low fence, this is one of the most beautiful of all climbing plants. Its botanical name is *Tropæolum peregrinum*, and it is nearly related to the common Nasturtium, another elegant and free-flowering climber, well known in nearly every cottage garden. Ten-week Stocks should now be sown in patches, and they will bloom in the course of a few months; while their flowers are nearly as sweet as Mignonette. Asters may be sown in the same manner, and hardly ever fail to produce their large richly-tinted double flowers. In addition to these, Larkspurs (purple and white), Snapdragons (*Antirrhinum*), Soapworts (*Saponaria*), and Clarkias should find a place along with *Collinsia bicolor*, Love lies Bleeding (*Amaranthus*), Candytuft (*Iberis*), *Eschscholtzia californica*, Lupins, *Nemophila*, and the rosy cushion Pinks (*Silene pendula*). The

above will grow and flower freely in any ordinary garden soil, and are quite as well worth growing as Geraniums, and other summer bedding plants; though, if possible, include both in your arrangement. As to the question of expense, any of the above seeds can be bought at any seed-shop in penny or twopenny packets; so that the cost is no serious obstacle to their culture. B.

WORK FOR THE WEEK.

The Flower Garden.

THERE are several kinds of evergreens that may now be transplanted, when the sap is in motion, with the greatest certainty; and, amongst them, we would particularly mention the Cedar of Lebanon, the planting of which during winter is attended with great danger; whereas, if planted now, the chances of failure are reduced to a minimum. Careful removal is necessary, however; and it should be done speedily, so as to expose the roots to the drying influence of the weather as little as possible. When the tree is in position, cover the roots with the finer portions of the soil, and tread it solidly down, giving a thorough soaking of water, which must be allowed to subside previously to filling up the pit. Mulch the ground above the roots, and little after attention will be necessary. Hollies may also be transplanted at any time during the spring months—a point worth knowing, for the best gold and silver kinds are unsurpassed by any other subjects for summer embellishment. The same remarks are applicable to Rhododendrons, and many other evergreen shrubs. Recently-planted trees and shrubs must have timely attention, in order to prevent their suffering from want of water and from wind-waving. In the case of large trees, indeed, staking is an important point. Re-plant *Cerastium* and other hardy edging plants. Violets, as they cease flowering, should be lifted, parted, and re-planted in ground that is in good condition. Fresh turfy loam and dung, forked into the soil where they are to grow, will be found to suit them perfectly. They delight in a situation shaded from direct sunshine, such as the north side of a wall, or in the shade of trees; but avoid inducing them to become drawn, by planting them under the spread of the branches. The best varieties for garden display are the Czar, the finest of all single Russian kinds; and the white sort, called compacta. Pansies and Violas may now be planted out into beds that are well enriched with manure, and to which fresh soil has been added; bearing in mind that perfect success is only attained by promoting continuity of growth. Sow seeds of hardy annuals, biennials, and perennials, and plant out Hollyhocks. In the case of *Oenothera macrocarpa*, part the roots. This showy sort may be propagated in heat by means of the young shoots. Among Oxalises, which should now be divided, *corniculata rubra* is a very pretty variety for carpet-bedding. The Striped Grass, *Dactylis glomerata variegata*, should now be propagated by parting the roots. Of the *Pyrethrum* well known as Golden Feather, a sowing should be made at once, upon a warm sheltered border. It will come in well for panels, where the plants cannot well be too small when planted out. Unoccupied beds should be treated in accordance to the crop they are to carry. In the case of Geraniums, a dressing of fresh soil will be more conducive to effect than one of rich manure, as over-luxuriant production of foliage proportionately diminishes the amount of flower; while, on the other hand, if an exuberance of leafage is desired, an abundant supply of nourishment must be given. Deep cultivation is important; for, except that is secured, no after management will compensate for its loss. Leaf-mould and thoroughly decomposed manure only should be used, avoiding rank dung. General ground-work must be proceeded with, and arrears of every description pushed forward. Cut Box-edgings; and, if any remain to be relaid, they must now be seen to. Mowing, rolling, and clipping the edgings of walks will now demand attention. Weeds must be kept under, and perfect neatness and order must be everywhere maintained.

Pits and Frames.

The majority of bedding-plants now occupying these may be placed under temporary protection, preparatory to being planted out. Attend to the pricking off of tender annuals, and push forward what potting off may yet remain to be done. Abundance of space and air should be afforded to the more tender bedding-plants, so as to ensure sturdy well-matured growth. Continue to make sowings of tender annuals.

The Fruit Garden.

Disbudding the shoots of Peaches and Nectarines, by only taking off a few at a time, till all danger from the influence of cold weather is over, must now, or soon, be proceeded with; and, where this is properly done, it adds to the beauty and health of the trees. Where the fruit has set thickly, timely attention to thinning must be observed. Apricot trees are often much infested with a grub, that

curls their leaves up and eats the young fruit. As this pest is safe from syringings or dressings of any kind, it must be searched for and crushed with the finger and thumb; and the more effectually this is done, the fewer grubs will appear next year. Peach and Nectarine trees on the walls, if infested with aphides, must be syringed with tobacco-water; and this, if done in time, will prevent them from injuring the foliage. Attend to the stopping of all fore-right shoots on Pears, Plums, and Cherries on the walls. In true orchard-houses—that is, where no artificial heat is employed—the temperature must be ruled by the weather. It is advisable, therefore, on bright sunny days, to close the lights early in the afternoon, to secure a higher temperature for the night. Disbudding and pinching all strong shoots, and thinning the fruit where set too thickly, will be the routine for this month. Green fly and red spider must be eradicated by fumigation, or syringing with tobacco-water. The Vines in the early houses will now be ripening, and some air left on at night will assist the colouring process. In the succession-houses, when the Vines are in flower, good fires must be kept up, and plenty of air given when the weather permits. Thinning the berries as soon as they are fit, stopping the laterals at a leaf or two above the bunches, and removing all superfluous shoots, will be the main points now to attend to in the latest Vineries. The coverings may now be removed from all the outside borders, and some liquid-manure applied to them when watering is necessary. The fruit in the earliest Peach-house will now be at its second swelling, and the border must be examined to see that the moisture is sufficient, especially where the roots are all inside the house. Abundance of air must be given when the fruit is colouring, and the watering at the roots gradually discontinued. The trees in the late succession-houses must be syringed every afternoon, and a moist atmosphere kept up to prevent red spider from injuring the foliage. Soft water, at a temperature as high as that of the house, should be used for this purpose, for hard water stains the foliage and fruit with carbonate of lime, and spoils the bloom on the fruit when ripe. The thinning of the fruit must be attended to, and the quantity left on be regulated by the health of the trees. I find the best soil for Peach and Nectarine borders, where such can be procured, is the turfy loam from old pastures or the sides of roads, and no manure or compost of any kind added to it. Peach trees grown in such soils never make too gross or unhealthy wood, and they can always be kept up to the desired vigour by an addition of fresh soil to the roots and liquid-manure during the time the fruit is swelling. All leaf-mould, old tan, or any compost or soil that is likely to bring Funguses into Peach-tree borders, should be strictly avoided when making them, for, when Fungus fastens on the roots of Peach trees, it soon renders them unhealthy and unproductive. As the first crop of Figs will be about ripening, the supply of water to the roots must be diminished, and only sufficient given to prevent the second crop from dropping off. The trees grown on walls after the winter coverings are removed will want their wood thinned, and all the shoots left nailed or tied in. As soon as the fruit in the Cherry-house is all gathered, the trees must get all the air possible by taking the lights off or opening them to their fullest extent. When grown in tubs or pots, the trees can be placed in the open air in some sheltered situation, and not neglected for water in dry weather. Syringe with tobacco-water or fumigate should the black aphid make its appearance on the trees. In the case of Cucumbers and Melons, a steady bottom-heat will still want keeping up, and by attention to syringing and a moist atmosphere the foliage will appear clean and healthy. The fruits on both Melon and Cucumber plants often set too many at a time, and require thinning, so as not to weaken the plants too much. Put pieces of slate or glass under Melons grown in frames, to prevent the damp soil from rotting the young fruit. When Melons are grown in pits and the plants trained on wires or trellises, the fruit, when getting heavy, must be supported on a square piece of wood with a piece of string fastened to each corner tied to the wires, leaving plenty of room for the fruit to swell to their full size. Plants in frames will still want covering up with mats at night, and continued till all danger from cold weather is over. The ridge Cucumbers sown in May will want planting out by the end of the month, and a suitable ridge or bed made with hot dung will want preparing for their reception. Vegetable Marrows will likewise want planting out at the same time, and in the same way. When the fruit is all gathered from forced Strawberries, the plants are often huddled together in some exposed corner and neglected; but such plants, if taken care of and planted out, will furnish fine fruiting plants next year in the open air. Some varieties, likewise, when planted out early, produce a good crop in the autumn, and notably Sir Charles Napier for one. If the ground cannot be got ready for planting them out till other crops come off, and the pots are wanted, the plants may be shaken out and packed closely together with a little mould sprinkled amongst them, when they will be safe till planting-

time, if supplied with water in dry weather. Take advantage of favourable weather to clean between the plants, and to mulch them properly in good time. Where the soil is light and open, tread it firmly previous to mulching. To make Pines swell off freely, now that the days are long and light, ought to be no difficulty. All that is required is method in the way of applying necessities, such as tepid manure-water, charging the atmosphere with ammonia and humidity, kindly airings occasionally, and never shading if well-swelled finely-coloured fruit is aimed at. Succession plants in every stage of growth should now get their full share of heat, humidity, and air, with a warm humid atmosphere. Air freely night and day, in order to get strong robust plants.

The Kitchen Garden.

In order that vegetation may make proper progress, stir the surface of the soil frequently and well amongst growing crops, by means of the hand-scarifier, Dutch and draw hoes. Unctuous, stiff, wet soils must be methodically trenched, exposing as much of them as possible to the influence of sun and air, in a rough ridged state. Forking, scarifying, hoeing, and otherwise loosening the soil, at all seasons amongst crops is the main point in good cultivation, giving neither vermin nor weeds a chance of existence. Make up vacancies by transplanting, or you tolerate a loss; everything can be transplanted by means of a trowel in each hand, one to open the hole and the other to take up the plant with a ball of earth attached to it. After-thinnings, when the plants are established, are made with crane-necked hoes, one in each hand, sharply looked after. Make the last sowing of some late Broccoli; prick off all previously sown plants as soon as they can be handled; also, those of Savoys, Brussels Sprouts, Borecole, and other Kales. Plant Cauliflowers out in succession now, on the coldest, dampest situations you can select, and make small sowings for succession. Thin early Carrots, and sow other early kinds in small quantities, in order to have always a succession of young roots. Plant Beans on stiff cold ground, and pinch the tops out of such as are coming into bloom. French Beans, transplanted or up and growing, dredge with dry dust, to prevent shanking or canker; shelter, where not under hand-glasses, with boards or boughs. Of Scarlet Runners, and other Runner Beans, plant a full crop, sheltering and dredging them as just recommended for French Beans. To early plants of Celery in frames give air freely, and water abundantly; earth carefully, remove the lights entirely now, and make use of them for sheltering and assisting the second crop for a short time, or for French Beans, Capsicums, Chillies, Sweet Basil, &c. Young Celery for succession, continue to prick out; never allow the plants to get large or drawn previously with large tap roots, if fine, crisp, and well-finished Celery is aimed at. The best situation for Celery at this season is in partial shade, that is, where tall late Peas have been sown in rows, 12 or 14 feet apart, as they always should be, in order to obtain a heavy, perfect crop, and where early crops of Spinach, Turnips, Cauliflowers, &c., have first been taken; between the Peas cast out a shallow trench, 6 feet wide, fork into it a good portion of good rotten manure, and plant seven or eight plants crossways in the trench, 18 inches apart. Thus treated, the result cannot fail to be a heavy crop of fine Celery, and that with less trouble, labour, and expense, than by any other method, and in this way all the winter crops can be conveniently sheltered and protected from severe frost. Sow Lettuces once a fortnight in drills, on well-prepared ground, to be thinned by hand or hoe; they will grow away much freer without "bolting" from seed, than when transplanted in hot dry weather. Of Peas continue to sow late varieties at good distances apart, in order to obtain good and perfect crops, and partial shade for intermediate cropping. Draw a ridge of earth up to within 9 or 10 inches of each side of all Peas up and ready for sticks, and place mulchings of decayed manure of some kind between the Peas, and the ridge on each side. It is astonishing how this benefits them by preventing evaporation, and it affords convenience for applications of water. Stop or pinch out the tops of all early-blooming Peas; and all late kinds and strong growers should be first stopped when 2 feet in height, and three or four times afterwards, in order to get heavy crops. Manure or fork the ground between crops of Seakale that have been cut; thin the crowns early to two or three shoots, according to strength, and apply dredgings of soot pretty freely in rainy, dark, cloudy weather. Seakale grows naturally in great abundance, and Asparagus may be found in many places on the Devonshire coast. Tomatoes should be planted out against walls, close fences, under hand-glasses at the bottom of steep sloping banks, or in warm valleys against stakes, &c.; they may be trained and led with one shoot up to any bare spots on walls between fruit trees, then stopped to till up. The Tomato is a wholesome fruit not grown or made use of in this country to the extent it should be. Radishes, Mustard and Cress, Chervil, and other salading, sow little and often.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWER AND FRUIT PICTURES
AT THE ACADEMY.

DIFFERENT classes of visitors to the Royal Academy Exhibition enjoy this annual display of British art from different, and more or less special and distinct, points of view. The opening day was, in our case, occupied with the great annual display from the garden point of view. A large class of highly accomplished artists devotes itself almost entirely to the painting of flowers and fruit, or to subjects in which they are made very prominent features; and from the methods which true masters of their art pursue in their selection of form, their adjustment of masses of colour, and the happy juxtaposition of suitable contrasts, the most skilful and highly-trained horticulturist may learn more than he expects if he has never carefully studied what one may fancifully term floriculture on canvas. The florist who works in a groove with a fixed idea, not always of a very elevated kind, will perceive, in the study of flowers treated as subjects for a picture, that mere formal regularity is abhorred by the accomplished artist. For instance, the florists' prize Pansies—flat as pancakes, and round as penny pieces, are no subject for his pencil, when seen "full face," as the exhibitor shows them on his perforated showboard, to display their perfection of flatness more emphatically. That such specimens are not triumphs of skill in floriculture no one will for a moment assert; nor will it be denied that the present mode of exhibiting is a convenient one for the display of their forms and colours. But, it will be well to note how the artist deals with that kind of formalism in the flower which has been the chief aim of the florist. He evades it—he glances above it—beneath it, shirks the "full face"—throws the splendid novelty into perspective, or shows a portion of the paler colours of the backs of the petals, and allows only a glimpse of the gorgeous hues of the front. Or, if one or more of the flowers are shown in a nearly (but never quite) front view; others are seen in profile, or with an entirely back view; and there is always a fair admixture of foliage, the several tones of green in the old, the young, and the already browning leaves forming an exquisite and contrastful background to the flowers, that, when well-managed, even the florist is charmed with, and the reason is that the laws of Nature are obeyed. Nature does not produce her flowers without leaves, nor do they all turn their faces in exactly the same direction, so that all may be seen in plump full face. The avoidance of the natural laws of plant growth is one of the chief causes of the Cauliflower-like aspect of some of the most costly Covent Garden bouquets. Even in the exhibition of Pansies, or Dahlias, it is by no means impossible that an artistically arranged bouquet, with a fitting portion of well-selected foliage would not prove more attractive to the spectator than a show tray with the decapitated Pansies or Dahlias, all in row, with which, however, it would always be useful to supplement the picturesque bouquet, like a tailor's card of waistcoat patterns, which, nevertheless, remains entirely subservient to the perfect suit. These remarks are intended merely to show that a good deal may be learnt from paintings of flowers, even by those who grow them. Miss A. F. Mutrie's "Poppies" form an eloquent illustration of the ideas that have just been touched upon. The work is a gloriously rich morsel of pure Nature, with its flowers, buds, foliage, and dewdrops *au grand complet*. The wild, informal, even unsymmetrical, luxuriance displayed is so elegant in its wildness, that the artist actually seems to have "snatched a grace beyond the reach of art." This group of cultivated varieties of the wild Corn Poppy, generally known as Carnation Poppies, are, in treatment and natural grouping, equal, if not superior, to the grandest compositions of Van Hysum himself; and, if superior, it is because the *ars celare artem* has been more skilfully and modestly observed by the English paintress. The great Dutch painter audaciously exhibits the art of his device, as a chief part of its merit; but, in Miss Mutrie's

"Poppies," there is no obtrusive display of the means by which her beautiful picture is produced. The grand flowers, heavy with the opulence of richly-tinted petals, reel in graceful carelessness to right or left, to or from the spectator, gently bowed by the weight of their own luxuriance, and seeming to revel in a nonchalant consciousness of their beauty. The charming varieties of colour which the different double varieties of Carnation Poppies assume, have rendered them great favourites. Sometimes a narrow band at the edges of the petals is milky-white, deepening to rosy-crimson at their bases, the profuse anthers and the markings on the green seed-vessel being of a soft sombre purple. In some varieties the whole petals are soft pearly-white, verging to grey, with a bright crimson band at the edges. The flowers of other varieties have the entire petals of dazzling scarlet, but deepening to intense purple-black at the centre. There is, in fact, no end to the varieties of and marking into which these Poppies capriciously sport; and Miss Mutrie has selected several of the most beautiful for her composition, the main character of which has evidently been founded on a real living and growing group. The treatment of the foliage is as fine as that of the flowers. The buds, especially, are wonderfully well studied; some are still small and green, and tightly closed; others, through a narrow opening from point to base, just reveal the colour of the still closely-folded and well-protected petals; while others, again, have just cast off their green night-cap, as Poppies do, and the petals are just beginning to expand. Some of the flowers have already lost their petals, which lie like butterflies' wings among the foliage; while the seed-vessels, graceful in form as a Grecian urn, and crowned with their radiated lids, are standing more erect, now that they are disencumbered from their heavy robing. One grand flower, over expanded, and truly glorious in its tinting but an instant since, has just shed the whole panoply of its beauty at the summons of a passing whiff of a June breeze; and the shreds of floral satin, such as no loom can match, lie a little heap of exquisite ruin on the gravel walk, a glimpse of which is shown. The border, roughly enclosed by low strips of wood, rain-stained and sun parched, and not a trimly kept one, is allowed to run half wild; and a group of wild Daisies nestles behind the wooden edging and forms a charming episode in the composition, which comes out clearly and sunnily from a back-ground of shrubs that are judiciously cast into a soft shadow. One more episode there is in this charming picture, which cannot be passed over. There are two gemlike objects gleaming brightly in the deep shade beneath the group of Poppies. Shakespeare, in one of the many passages in which he asserts that in all created things, even the most repulsive in general aspect, there is always some latent beauty, tells us that, "the toad, hath yet a jewel in his head"—alluding to the splendour of his eye. The two gemlike objects glistening in the partial darkness of Miss Mutrie's gorgeously luminous Poppies are the jewels in the head of a crouching toad, more truthfully painted, if possible, than the flowers themselves. It is a feature, however, so carefully subdued and kept out of prominence, that few who are not guided towards it by the small beacon light of those marvelous eyes will ever notice it, but a gardener would, at once, for he knows that his friend the toad is one of his chief slug destroyers. Miss M. D. Mutrie, a relative of the preceding artist, has a pretty study entitled "Camellias and Azaleas" (972), white and rose Camellias are placed in a shallow tazza with a spray of scarlet Geranium by way of contrast. The Azaleas are represented by a plant of a pink variety growing in a common red-clay pot. Its growth has not been trimmed, and its branches have made their natural growth, which is somewhat angular, and are well clothed, but not smothered with flowers. The picture is fresh and natural. Mr. Hardwick, under the title of "Spring Flowers" (795), has a pretty group of early blossoms from both field and garden. Here are Lilac from the shrubbery, Hawthorn from the roadside hedges, and Primroses from the banks and woods; a pretty group, placed naturally and without any painful attempt at symmetry, in a simple jar. The artist has four other subjects, Nos. 650, 778, 800, and 803, among which (800) "Roses and Nasturtiums, a study of colour," is very suggestive in regard to contrasts of tone, and light and shade. "Spring time" (861) has furnished Miss Chase with a pretty model in the form of a

deeply-sheltered meadow nook, in which Cowslips, Daisies, and Blue Bells are blooming together; and a pleasant little spring party they make; though the treatment is somewhat conventional, and the growth of the thick early Grasses has not been sufficiently studied. The artist has another subject (899)—“Sprays of ripe Blackberries,” which may remind us of what Americans have made of Bramble culture; but, one must recollect, at the same time, that the Blackberry, which American horticulture has made a delicious fruit, is, in appearance, much more tempting and luscious looking than the berries represented by Miss Chase. Mrs. Duffield has a charming drawing (892), entitled “Fallen petals.” The subject consists of two pale yellow Roses which deepen to rich orange in the heart of the centre. They are possibly flowers of that beautiful and favourite Rose, *Maréchal Niel*, or perhaps of some newer kind of the same group. They appear to have been laid carelessly upon a Mossy bank, and the petals of one have, apparently just fallen, a little shower of golden snow-flakes. Nothing can be more artist-like than the whole treatment of this simple theme. “A labour of love” (961) is a prettily treated flower subject. Surely nothing connected with the treatment of flowers, whether in the garden, or on paper, or canvas, can be other than a labour of love. The “labour of love” consists in this composition in the arrangement by a pair of delicate hands, guided by an evidently appreciative instinct, of a harvest of freshly-gathered Roses. The idea is pretty, and so is the picture. “My First Bouquet” (1,342) is another work of the gifted Miss A. F. Mutrie. It forms a sad and sorrowful contrast to the exquisite Poppy picture; not because it is worse painted, or that any one of the flowers is touched with a less skilfully-directed brush, but it is an absolute *fac simile* representation of one of the Covent Garden Cauliflower bouquets, even to the minutest detail of the lace-paper envelope. Surely this is a desecration of such talent as that of Miss A. F. Mutrie. But, perhaps, it was “a commission;” perhaps there really is a young lady who received the original of that painted bouquet—her first authorised present of the kind—from one of those irresistible languid Adonises with “sad eyes and beautiful gloves,” who are allowed to be such fascinating creatures; and she immediately rushed to Miss Mutrie’s to have its every flower reflected in undying colours by the magic touch of art before it had time to fade. Let us hope it may be so; for, if so, the sentiment was “sweet,” though the bouquet, despite the beauty of each individual flower thus lumped together, is odious. Cannot the Covent Garden bouquet-makers let us have a choice; cannot they exhibit a few, ever so few, gift bouquets, grouped in that grand free old nosegay and posey style, which our old flower painters loved to reproduce on their oak panels, and Grinling Gibbons delighted to carve out of the solid oak itself? There surely would be found a few customers who would prefer a freer style, in which a due proportion of the foliage of each plant should mingle, instead of endeavouring to make it appear that Maiden-hair Fern alone bore flowers of all kinds, from Camellias to white Lilacs, scarlet Geraniums and Lilies of the Valley. No. 872 is a fruit subject, painted by Mr. Sherrin. It is simply a sturdy branch thickly studded with magnificent Plums, ripe and luscious, with the velvet bloom so rich and full upon them, that one fears to approach too closely lest he might brush away some particle of that powdery beauty. The branch leans against a bank partially clothed with rich olive Moss, and the general treatment closely and successfully approaches the style of those well-remembered fruit subjects by Hunt which were for so many years the charm of the senior Water Colour Exhibition. This subject might suggest to growers of choice fruit for the table that it would be a far more elegant and refined method of displaying it, to place it on its plateau, still attached to its native branch, no finger ever having touched the fruit itself. There are several other flower and fruit subjects worthy of notice, but space scarcely remains for the brief description of a few figure subjects, which combine the prominent introduction of flowers. The most important of these is the “Pot Pourri,” (129), by Mr. G. D. Leslie, a very delightful picture. There is, perhaps, a little too much of mere prettiness in the charming pair of fresh young girls rejoicing in the very flush and bloom of youth. Yet, as their delicate fingers sprinkle the dried Rose leaves into the great

china jar, and one of them holds up a handful in a living cup, formed by rosy fingers, more delicately tinted than the crisp petals she is handling, in order to inhale and test the quality the perfume, the picture must certainly be pronounced a very attractive one. Let us hope that, seeing the interest which young ladies take in the manufacture of pot pourries, that our Rose growers will at once send out lists of the best kinds for the purpose, especially those whose dried petals preserve their perfume the longest. No. 1,385, entitled “5 o’clock,” that is to say, 5 o’clock tea, represents a comely lady, seated in a conservatory, full of long borderings of *Lycopodiums*, and richly elegant with feathery Ferns and half-hardy Palms, all fresh and dewy-looking, from recent waterings. There is scarcely in all the exhibition a picture, in any way connected with fruit and flowers, that does not afford some kind of hint more or less worthy of note to a horticulturist. No. 1,350 is called “A Venetian Fruit Seller.” A wiry young fellow has just driven his boat close up to the back door of one of the great palaces, opening in the rear to a narrow canal, by a dexterous stroke of his single oar. A Venetian servant girl is waiting for the arrival of the daily supply, which consists of Onions, Leeks, Grapes, and Garlic—and, piled high in the boat, is a great heap of mighty Italian Gourds, of every variety of strange shape—some elongated to a curious extent, some whole, and some cut, to sell by weight—showing their rich scarlet-orange flesh. There is a somewhat ambitious picture, called “Covent Garden in 1873,” representing the arrival of fruit and flowers in the early morning. The figures, nearly half life-size, are well drawn, and the colouring has the merit of sobriety; but the fruit and flowers displayed are scant in quantity to a poverty-stricken degree; and in quality so poor, shabby, and stunted, that, few as they seem to be to meet the greedy demand of each day, even their rarity would be of no advantage to them; “they wouldn’t sell!” not at any price. One would like to have spoken of Mr. Faed’s “Violets and Primroses,” Mr. Yeame’s “Flowers for Hall and Bower,” Mr. Poole’s “Grape-gatherer,” and many other works; but the allotted space is already over full, and there is scarcely room to tell gardeners that they have every reason to be proud of this section of the exhibition; for, with the exception of the wild flowers and the Blackberries, they have furnished both the flower and fruit models for all those charming pictures.

Levelling the Malvern Hills.—Digging down the Malvern hills, has, it seems, been seriously contemplated. The available agricultural land of England, in proportion to its population, has been long a subject full of the darkest doubts and forebodings to those who are always on the look-out for imaginary rocks ahead. Under the excitement of such reflections the idea of levelling the Malvern Hills, and so rendering the area which they cover amenable to the production of human food, made so strong an impression upon the brain of a certain Mr. Johnstone, of the hamlet of Colwall, situated near the foot of the Herefordshire Beacon, that he determined to devote his fortune, which was considerable, to this, as he deemed it, most sacred purpose. He commenced, and long persevered gallantly, in his self-imposed task. But death overtook him, the other day, “before he had completed the great work,” though he had succeeded in making a tolerably big hole in the beacon. He must one would think, at some time or other, have come across the remarks of the American traveller in Switzerland, who said that the tiny Republic indulged in very tall talk about its high mountains, and that all the people were a good deal stuck up themselves on that account—and that it was an “almighty pity” the said mountains were not rolled out flat, as by that means the tiny Republic might attain the dimensions of a respectable little State.

THE Duke of Devonshire, who has only recently completed the formation of an extensive recreation and cricket-ground at Eastbourne, has expressed his intention of executing further works for the benefit of the town at an estimated cost of £16,000. The want of a large assembly-room has long been felt, and his Grace intends erecting a spacious pavilion, 350 feet in length, on land near the new cricket-ground. While providing a large hall for meetings, space will also be afforded for a public library. Adjoining will be winter gardens and a skating-rink. The whole of the fittings and appointments will be of the newest and most complete description. The land recently devoted to the town of Eastbourne by his Grace comprises about thirteen acres, in the best part of the town, and would realise for building purposes £30,000.

NOTES OF THE WEEK.

— THE bitterly cold weather has cut short the supply of *Asparagus* to Covent Garden market in a marked degree, and prices have run up considerably in consequence.

— THE bunches of *Lily of the Valley*, seen in such profusion in the London streets during the past week, come to us mainly from the neighbourhood of Toulouse. Many thousand large bunches were received in Covent Garden during the past week. These were sub-divided into the small bunches seen in the streets. These *Lilies* come packed in boxes, with abundance of their own leaves, and travel well.

— APRICOTS from Spain are now selling in Covent Garden; they are the variety known as the *Kaisha*, and come from Valencia. What a pity it is that wars and revolutions make progress in cultivation and fruit growing almost impossible in this fine country; whereas, in parts of America, not yet settled twenty years, these arts are in a highly advanced state. The South of France sends large supplies to our markets; whereas Spain, though possessing a more favourable climate for early crops, sends, as yet, very little.

— LEICESTER Square is nearly finished, and it is, we regret to say, a failure as regards design. All the prettiest and best designed squares we know of, have an open Grassy centre, and the walks not more conspicuous than is necessary. Leicester Square has a large fountain and basin in the centre, and this, with the very conspicuous walks, cuts up the surface so much, that a poor, confused, and altogether too gravelly and stony effect is the result. An imposing fountain in the centre of a small garden, or a fountain of any kind, is always a mistake, and particularly in our wet climate, to the charms of which a dripping fountain is no addition at most times.

— LOVERS of hardy herbaceous plants will find now, at Kew, various plants in bloom not generally to be seen in private collections. Among these may be named *Anthemis Aizoon*, a silver-leaved dwarf species, of which there is a nice tuft on the rock-work studded with showy white flowers; *Ranunculus illyricus*, a species somewhat resembling *R. gramineus*, but having glaucous leaves and larger flowers; a good tuft of *Anemone vernalis* nicely in bloom; also *Silene maritima rosea*, a desirable variety of the well-known Sea Catchfly, with fleshy-rose-coloured flowers; several plants of *Viola palmata*; *Hedysarum obscurum*, with deep rose-coloured flowers; *Saxifraga corsicana*, a distinct kind of the mossy section of *Saxifraga*, studded with large white flowers; and the beautiful blue-flowered *Pulmonaria dahurica*. That beautiful shrub *Viburnum macrocephalum* is also just now producing large and fine heads of bloom in such abundance against a wall in the herbaceous department as to be conspicuous even at a distance.

— THE visit of the Emperor of Russia has led to the raking up of many anecdotes connected with the visits of former Russian potentates, the first having been Peter, the Isar of Muscovy, afterwards known as Peter the Great. In the "Diary of Evelyn," which contains so many memoranda of interest to gardeners and lovers of horticulture, it appears that the Isar, in order to pursue his studies connected with shipbuilding, had taken up his quarters at Sayes Court, close to Deptford Dockyard. Mr. Evelyn's butler, it is recorded, wrote to his master a very disparaging account of the inhabitants of Sayes Court, consisting of the Isar and his Russian attendants, to the effect that the house was full of people "right nasty;" and that the Isar himself had, as a short cut to the dockyard, wheeled his barrow right through his master's (Mr. Evelyn's) quickset hedge. On being reminded that such conduct was a transgression of the law, the Isar retorted we had a great deal too much law, and that he had only two lawyers in the whole of his dominions, and intended to hang one of them immediately on his return.

— COMPLAINTS reach us from all sides as to the grievous damage done by recent frosts. In the London districts and the home counties the destruction is appalling, even to those well accustomed to our too-often severe springs. Fruit trees, *Roses*, *Coniferous* trees, *Rhododendrons*, and other "American plants," even the *Ivy*, and numbers of our hardiest herbaceous plants and commonest trees, such as the *Oak*, the *Ash*, and the *Laburnum*, have been very much injured—too often killed back to the old wood. The poor *Lilac*-blossoms, and other flowers of the spring-trees have been in many cases burnt up, as if with fire. Oddly enough, while the nights have been clear enough to permit of severe and prolonged frosts, the days have mostly been overcast, and with winds of unusual bitterness, which seem to have worked with the frosts in producing such unexampled destruction. The frost has also been severe in Nottingham and elsewhere in the Midland counties. At Retford, the thermometer indicated 11° of frost; in the gardens at Thoresby there were 10°; at Ollerton equal severity; but at Budley, three miles northwest of Ollerton, there were 12° of frost, the ice in the shade remaining till the afternoon. Vines have suffered considerably at Auxerre, Chalon-

sur-Saone, Dijon, Clermond-Fer and, and in a portion of the Médoc district. In Jersey, Potato crops have been greatly injured, whole fields in some parts of the island having been destroyed.

— At the Royal Horticultural Society's meeting on Wednesday last, Mr. Terry of Peterborough House, Fulham, exhibited a specimen of *Medinilla magnifica*, bearing about eighty fine drooping spikes of bright rosy inflorescence.

— WE have received from Messrs. Sutton & Sons, of Reading, specimens of their Late Queen Broccoli, a sulphur-coloured kind just now in perfection, the heads of which measure 27 inches in circumference. It is the latest Broccoli in Messrs. Sutton's trial grounds, and, owing to the size of the heads, their closeness, and fine form it promises to be a great acquisition to late Broccolies.

— WE regret to announce the death of Mr. John Salter, the venerable and well-known Chrysanthemum grower, formerly of Versailles, and more recently of Hammersmith, which took place on the 18th inst., at the age of seventy-six. His nursery, one of the most interesting of those devoted to hardy plants in the neighbourhood of London, was broken up some years ago, in consequence of the District Railway requiring the grounds, since which time he has lived in retirement at Kensington.

— THE Board of Works have purchased the manorial interest in Clapham Common for £17,000; they do not, however, propose to make any alteration, but simply to secure it from the threatened innovations of speculating builders. Here, therefore, we shall have an open space "left to Nature," where the green hillock will be allowed to remain, and the Heather, Furze, and wild flowers allowed to grow undisturbed.

— WE have received from Mr. Samuel Gale, of 320, Oxford Street, specimens of indelible stamped zinc garden labels, suitable for *Roses* or fruit trees. The zinc of which they are made is oxydised, thus making it easier to read than the bright glittering surface of quite new metal. The best method of attaching these labels, which are of various forms, is by means of a piece of tarred string. They are cheap, durable, and neat in appearance, and, evidently, an improvement on many of the kinds of labels now in use.

— WE learn that Messrs. Weeks's decorations on the occasion of the opening of the Thames Embankment were of a very effective kind. Spanning the entire front were three arches tastefully draped, while baskets of choice flowers depended from the front of the building. Among other plants employed, were *Dracæna australis* and *terminalis*, *Yuccas*, *Callas*, *Clematises*, and a large collection of *Pelargoniums* and other flowering plants, the whole making a display at once interesting and striking.

— AT Messrs. Webber's stand in Covent Garden may have been seen some of the finest *Asparagus* yet observed in London. It is of English growth, being from the market garden of Mr. Dancer, of Little Sutton, and is of as good quality as the best French growths. It has been grown on the usual French plan of leaving a considerable space between the plants. The variety grown by Mr. Dancer is one called Conover's Colossal, which he supposes to be distinct from the common *Asparagus*. The produce from the French gardens has been very fine this year, excellent specimens being now seen in Covent Garden, and the fruiterer's shops elsewhere.

— NOTWITHSTANDING exceedingly bad weather, the opening of the International Flower Show at Florence, on Monday last, passed off in a most satisfactory manner. The ceremony, which took place at twelve o'clock, was performed by King Victor Emmanuel. His Majesty was accompanied by several of the ministers and by the members of the corps diplomatique. Nearly 300 botanists from all parts of the world were present, besides a large number of foreign visitors. The show took place in the new market, a splendid building, the architectural features of which are very striking. Professor Ancona read a discourse in which he traced the history of horticulture in Florence. The king expressed his gratification with the exhibition, and spoke with several of the principal botanists present. The floral decorations were especially effective.

— AN American botanist, Dr. H. G. Farlow, has made an interesting discovery in the reproduction of Ferns. He has observed the development of true Fern plants directly from the substance of the leafy body produced by the germination of the spores of a Fern (*Pteris serrulata*), and quite independent of any reproductive organs, and he states that the plants thus produced were quite undistinguishable from those which arise in the regular way by way of fertilisation. A few nearly similar cases have been recorded in flowering plants, the seeds of some female flowers having proved to be fertile when there appeared to have been no possibility of their having received the influence the pollen, and this observation of Dr. Farlow's is of importance as tending to confirm these supposed cases of parthenogenesis, as it is called, in plants which have hitherto been regarded as not thoroughly well established.

THE GARDEN IN THE HOUSE.

ANEMONES AS WINDOW PLANTS.

ANEMONES are fine plants for culture in boxes on the balcony, or in the open border. These, and all other hardy plants cultivated in pots for window decoration, should be plunged (after flowering) in a bed of sifted coal-ashes, or Cocoa-nut refuse. This keeps their roots cool, and in an equable state as regards moisture. When they show flowers, the pots can be washed, and then removed to the drawing-room to expand their richly-tinted flowers. The common *Hepatica* (*A. hepatica*) is one of the most beautiful of all spring flowers, and may be used in balcony-boxes with excellent effect along with *Arabis alpina* and its variegated variety, *Aubrietia purpurea*, or *A. græca* *Saxifraga umbrosa* (London Pride), *S. crustacea*, a small-growing species, the leaves of which look as if set with little pearls, and many others. Any of these may be used for edgings, and the centres filled in with *Snowdrops*, *Crocus*, *Tulips*, *Hyacinths*, *Winter Aconites*, *Scillas* (Squills), *Bellis aeneæfolia* (Red Daisy), any or all the numerous beautiful varieties of the common hardy *Primrose*, white *Lilac*, red, crimson, and purple; and last, but not least, scatter a few seeds of *Myosotis dissitiflora*, over the boxes in the autumn, or prick in a few plants, and your window-boxes will be a treat, both to yourself and neighbours, during the warm sunny days of spring. Anemone roots may be bought in the market any time during the autumn, and should be planted forthwith. The roots of some Anemones will grow after being stored in a dry place for two or three years, still they are considerably weakened thereby. The popular name Wind Flowers, also belongs to the genus *Zephyranthes*. *Anemone japonica*, *A. japonica alba*, *A. hortensis fulgens*, and *A. vitifolia*, make fine specimens, plunged in pots ready for removal to the window or balcony in autumn, when their flowers expand. All hardy plants should be kept cool, and have abundance of fresh air whilst flowering, after which they should be again plunged outside. *Anemone japonica*, and its varieties, is one of our best autumn-flowering hardy herbaceous plants, and its large pure white flowers are very useful in a cut state. When taken up out of the ground and potted, it is also very serviceable in the conservatory or window-garden. For this purpose it wants a good soaking of water, and should be put in the shade for a few days until thoroughly established. B.

ROOM PLANTS AND INSECTS.

THERE are insects that multiply by hundreds, and destroy the labour of months in a very short time, as we know they have often done in many places. Those who have glass-houses can control the various insects which destroy foliage and prevent plants from flowering, for they have only to close the sashes and doors, and to light a pile of tobacco refuse, and the insects forthwith depart. Ladies, however, who keep plants in windows during winter, and on balconies in summer, are not able to do this; but if they possess a tobacco-loving biped, they might devote his admiration at the shrine of tobacco to some practical purpose, by requesting him to so arrange his morning and evening devotions, that the smoke of his burnt-offerings might mingle with the leaves of their pet plants, and thus keep their branches and foliage free from those pests—green fly and red spider. If, however, their possessions do not include this species of humanity, they can brush away the aphids with a feather, by placing the pot upon paper, on a stand, and afterwards burning the paper. Red spider is not easily diverted from his destructive course; so it is often needful to immerse the whole plant in strong tobacco liquor for ten or fifteen minutes, to dislodge him from his winter and summer quarters. This minute insect is one of the most detestable pests which infest house plants, and many a stand of plants is ruined through his agency. His presence is known by plants not having a healthy appearance—when their leaves curl up, and their bright green hue is gradually assuming a dingy look; under such circumstances apply the smallest of microscopes to the under surface of the worst looking leaves, and the disastrous effects will soon be perceived. The leaf will be found covered with red tiny mites, sucking out its strength and vigour. Roses, Carnations, Geraniums, Heliotropes, Fuchsias, and similar plants, are the favourite haunts of these red marauders, and often they take up their abode in foliage for summer and winter, unmolested, because the owner of the plants know not of their peculiar habits. The flowers are not produced, but the reason is unknown. If badly infested, tie something over the top of the pot to keep the earth from falling out, and then immerse the whole plant in soap suds or tobacco-liquid. Then take it out and dip it into pure water, to rinse off the suds or tobacco thoroughly. Perhaps the tenderest shoots may be injured, but that is no matter, because the plants generally

need pruning to recover their vigour after having been the abiding place of insects. Ivies are often infested with slugs, which live on the under sides of the leaves, and cause white spots to appear upon the upper side. A sponge dipped in carbolic acid, soap-suds, or tobacco-water, and wiped over every leaf thus affected, will usually cause them to disappear. Pure water must be used to wash off the suds; make the latter quite strong. The tiny white worms which sometimes appear in the soil of house plants, and which feed upon their roots, are also most inimical to their health. Roses, Carnations, and Geraniums have been injured by scattering salt over the surface; but red pepper will destroy them, and yet will not injure the growth of the plant. Brown scale, when it occurs, must be picked off with the fingers, or brushed away with an old tooth-brush. This insect is very pernicious to all woody plants, as it clings to their stems and sucks the life-blood out of them. Repeated washings and showerings will not dislodge it, but a touch of the finger-nail will destroy it, and often a warm bath of tobacco liquor will make it loosen its hold. The effect of the tobacco liquor and other liquid destroyers should be tried first upon some plant of little value before such as are more costly are subjected to its influence. Plants infested with insects can never present a pleasing appearance, and if the bark and leaves be covered with dust and impurities, their peculiar functions are nearly destroyed, as the leaves are the lungs of plants; and, if the tubes be closed, the plant barely lives, and cannot blossom. DAISY EYEBRIGHT.

Dielytra spectabilis as an Indoor Plant.—The late frosts have in most places spoilt the beauty of this charming plant. It would be interesting to learn how much frost it will bear with impunity. I find from experience that it is safe with 5° of frost, but that 7° or 9° take nearly all the colour out of the flowers and leaves, while from 10° to 12° cripples it utterly. Pity it could not be induced to flower later, so as to be out of the reach of frost; most seasons of late years have been hard on this plant, marring, if not utterly ruining its beauty when in its prime. It is well worth a place in the conservatory, and in hanging baskets scarcely any plant has more grace and beauty. It is also well suited for a vase or stand, or for a window rest on a staircase. The white variety, too seldom seen, is also very beautiful when associated with the pink kind.—D. T. F.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Dwarf China Rose.—I have had a plant of this Rose in my window for the past month, and it is still flowering freely and most deliciously scented. I consider it one of the prettiest of all spring-flowering kinds for pot-culture.—Q.

Italians and Perfumes.—The modern Italians, especially those of the more southern parts of Italy have a peculiar horror of perfumes. They consider them remarkably unwholesome, and the Roman or Neapolitan lady requests her visitors not to use them. What is very strange, the nostril so susceptible to a perfume, is wonderfully obtuse to its reverse.—LORD LYTTON.

Mesembryanthemums the best Window Plants.—Few can know the value of this genus without seeing the plants growing in the open air, in a warm country, such as the South of Europe, where they fall down the walls and rocks in graceful curtains, and are now dotted over with rose and crimson stars. The important fact for the window-gardener to bear in mind is, that all *Mesembryanthemums* grown freely in sunny windows, and allowed to trail down from the pots, are, when in blossom, the most beautiful of window plants.—W. R.

German Ivy as a House Plant (*Senecio mikanooides*).—This is a rapid-growing Composite plant, and one of the best of all quick-growing climbers for window-culture. It strikes freely from cuttings, or it may be layered, as its roots freely from every joint, and plants so obtained soon develop themselves, and, if potted in a rich compost and liberally supplied with moisture at the root, run round a window-trellis in a few weeks. It has bright shining leaves, somewhat resembling those of Ivy, but it is a much quicker-growing plant than Ivy. It is grown by the thousand on the Continent as a window plant, but as yet it is rare in this country.—B. F.

The Lily of the Nile as a House Plant (*Richardia æthiopica*).—This does remarkably well in a room window. A plant which I have of it has bloomed every spring for these last five years, but this year better than I ever saw it, having on it four fully-developed flowers. I think this is owing to my having given it a liberal shift, potting it in a rich compost of fibrous loam and well-decayed manure in equal proportions. I keep up abundance of moisture at the root; indeed, the saucer in which the pot stands is generally half-full of water, and this the plant seems to enjoy, as it grows vigorously, each succeeding leaf being large and taller than its predecessor.—J. BIGGS, *Belgrave, Leicester*.

Virginian Creeper as a Town Plant.—This is peculiarly a town plant, growing, as it does everywhere, either in shade or in sunshine, and it is, moreover, by no means particular as to soil. For hiding bare walls, or for covering trellises, porches, or arbours speedily, it is one of the best of all climbers. Now is the time to plant it, and it should be regularly watered until it has become established. No plant looks prettier than this during the summer, when its green leaves and ruby-tinted shoots droop gracefully over a balcony, or trail round a window-trellis; while, in autumn, its gorgeous crimson colours last good for several weeks. If contrasted with other climbing plants, as Ivy or Wistaria, so much the better.—W.

THE INDOOR GARDEN.

JUBÆA SPECTABILIS.

THIS very handsome Palm, known, also, as the Coquito Palm of Chili, is the only species of the genus, and is one of the most southern of American Palms. It has a stout trunk, swollen in the middle, which, in its native country, sometimes attains a height of nearly 40 feet. The summit is surmounted by a crown of large, spreading, pinnate leaves, of a full deep green colour, and from 6 to 12 feet long, the leaflets being from 1 to 1½ feet long, and about an inch wide, springing in pairs from nearly the same spot, and standing out in different directions. The leaf-stalks are very thick at the base, where they are enclosed in a dense mass of rough brown fibres, which grow upon their lower edges. In the account of the Royal Gardens, at Lisbon, given at p. 292, Vol. IV., of THE GARDEN, mention is made of a specimen growing there in the open air, which has attained a height of 32 feet, and the trunk of which measures 13 feet 8 inches in circumference at its base. "In Chili," says the "Treasury of Botany," "a sweet syrup, called Miel de Palma, or Palm-honey, is prepared by boiling the sap of this tree to the consistence of treacle, and it forms a considerable article of trade, being much esteemed for domestic use as sugar. The sap is obtained by the very wasteful method of felling the trees, and cutting off the crown of leaves, when it immediately begins to flow, and continues to do so for several months, until the tree is exhausted, providing a thin slice is shaved off the top every morning, each tree yielding about 90 gallons. The nuts are used by the Chilian confectioners in the preparation of sweetmeats, and by the boys as marbles. A quantity of them was brought to this country a few years ago, and sold under the name of Little Coker-nuts." The soil for this plant should be a mixture of one-half rich loam, and one-half a compost of peat, leaf-mould, and sand. It withstands our winters in the open air near London, in a poor condition, but, if grown in tubs in the conservatory in winter, and placed in the open air in summer, it will prove an excellent subject for association with the hardier Palms.

Jubæa spectabilis.

TREE-FERNS.

(SUB-ARBORESCENT SPECIES.)

OWING to the differences of opinion which often exist as to what is or is not a tree-Fern in certain stages of growth, I have been induced to separate a number of species from my enumeration of tree-Ferns, and to include them in a section which I shall term sub-arborescent kinds. These, while they represent to a certain extent the noble character of the Tree-Ferns proper, are specially suitable to cultivators who have small houses.

Brainea.

This is rather an anomalous genus, which is characterised by an erect caudex; the fronds are pinnate, veins "flabellately forked; the lower venules angularly anastomosing, forming a costal row of oblique cuneiform areoles. Sporangia produced on the transverse-curved veins and bases of the free venules, constituting a broad continuous or sub-interrupted transverse naked sorus."

B. insignis.—This is the only species belonging to this genus hitherto discovered, and no other known Fern can be added to the genus on account of the great peculiarity of its habit, its venation, and its manner of fructification. It produces a stout stem, which is said to attain a height of 4 feet, the largest I have seen being about 2 feet, and this was evidently of considerable age. The fronds are pinnate, and from 1 to 3 feet or more in length; upper side light green, almost glaucous beneath, base of the stipes and crown of the plant furnished with light brown chaffy scales; habit very graceful, rendering the plant worthy of a place in every Fernery. It enjoys a liberal supply of water at its roots, but I have always found drip or sprinklings from the syringe to turn the fronds brown; therefore, this should be avoided. It is usually considered a stove species, but it thrives admirably in an intermediate house. The only recorded localities for this plant are Hong Kong and one place in Khasia.

Didymochlæna.

This genus consists of only one species. It is characterised by having both pinnae and pinnules jointed with the rachis or main stem, and by its terminal, oblong, punctiform sori, and oblong hippocrepiform indusium.

D. lunulata.—The stem of this distinct and handsome Fern is erect, stout, and sub-arborescent; the fronds are erect, from 3 to 6 feet long, bipinnate, and broadly lanceolate in shape; pinnules nearly an inch long, obliquely rhomboid, sub-sessile and articulated with the rachis; they are dark heavy green in colour when mature, but,

when young, tinged with dull reddish-brown. The stipes and rachis are densely clothed with large brown chaffy scales. This is a superb stove Fern, and is admirably adapted for planting near the margin of water in a Fernery arranged on the natural system; indeed, when this plant fails, the evil is chiefly owing to want of attention in keeping it duly supplied with water. I have already remarked that the pinnæ and pinnules are articulated with the rachis, and, if the plant is allowed to become dry, these fall out at the joints, leaving nothing but bare stems in place of broad rich deep green fronds. It should be potted in equal parts of loam and peat, with the addition of a small portion of sharp sand. As before remarked, keep it well supplied with water, and place it in the shade, when it will not fail to be a source of pleasure and attraction to all beholders. It seems to be widely distributed through tropical America, as well as South and Western Africa, and several of the East Indian islands.

Lomaria.

This genus contains many species and varieties, but only those which form an erect caudex will occupy attention in this place; they have distinct, dimorphous, barren, and fertile fronds; in the former the veins are forked and free, but, in the latter, there is a continuous line, running transversely with the veins upon which it is situated, and, in general, in such abundance as to spread over and entirely conceal the whole under-side of the contracted fertile pinnæ. They are mostly strong-growing plants, or, at least, plants of a robust constitution, and should be potted in two parts loam, one of peat, and sufficient sand should be added to make the whole feel gritty when taken in the hand.

L. gibba.—No more useful Fern is in cultivation for general purposes of decoration than this species, and, therefore, I place it at the head of the list. When well-grown, and with all its fronds perfect, it has a rounded vase-like appearance, which is truly beautiful. The fronds upon old specimens attain a length of from 18 inches to 2 feet; they are broadest at the upper end, spreading, deeply pinnatifid, and shining bright green in colour. At first, the plant does not form an erect stem, but has a tufted appearance; with age, however, it builds up a trunk some 2 or 3 feet high, which varies considerably in stoutness in different individuals. It grows naturally by the margins of streams, which is a sufficient indication that it enjoys an abundant supply of water. It grows most luxuriantly in the stove, but stands uninjured in the cool-house, and, whilst young, may be used with much effect for the decoration of apartments, the dinner-table, &c. Native of New Caledonia.

L. magellanica.—This species rejoices in upwards of a dozen synonyms, the true form, I believe, not being very plentiful in cultivation. The stem is stout, attaining a height of from 1 to 2 feet, the crown and stipes being clothed with a dense mass of long, narrow, dark brown bristle-like scales; the fronds are from 1 to 2 feet long, pinnate, the pinnæ being very coriaceous in texture, entire, linear-oblong, and obtuse, dark green on the upper side, inclining to rusty-brown below. It is a splendid cool-house Fern. Native of the Straits of Magellan, Falkland Islands, Chili, &c.

L. cycadifolia.—This, although distinct-looking, cannot, perhaps, claim specific rank, and will have to be looked upon as a variety of the preceding. The stem is stout and massive, attaining a height of 3 and 4 feet; the fronds are from 2 to 4 feet long, pinnate, the pinnæ being dark green above, inclining to bright tawny beneath, whilst the stipes and crown of the plant retain the peculiar narrow dark brown bristle-like scales of the species just described. It is a superb species for the cool-house, and will be found sufficiently hardy to stand in the entrance hall, or similar situations, without injury, when not in a growing state. Native of Brazil, Chili, &c.

L. discolor.—This fine species is a native of New Zealand, a country so rich in Ferns of distinct character and pleasing effect; the stem is stout, attaining a height of from 2 to 3 feet with age, the fronds are from 1 to 3 feet in length, coriaceous in texture, deeply pinnatifid, the pinnæ are variable in size, linear-oblong, dark shining green above, paler below, sometimes approaching to reddish-brown; the stipes are dark-coloured, and, together with the crown of the plant, furnished with dark reddish-brown hairs. It is an extremely handsome and desirable species for the cool Fernery.

L. L'Herminieri.—This is a miniature tree; indeed, we have never seen a stem more than 6 inches high, but it is, nevertheless, a stem, its size and peculiar beauty rendering it a veritable gem for the Wardian case. The fronds are from 6 to 10 inches in length, widest in the upper part, deeply indented at the edges, but more pinnatisect than pinnatifid; in a young state they are of a brilliant crimson, which changes with age to deep green. Native of Brazil, Caraccas, &c.

L. Fraseri.—A rare but most elegant species, rising upon a slender stem to the height of 2 and 3 feet, or even more. The crown of the plant is furnished with short brown scales; fronds from 1 to 2 and

even 3 feet in length, they are deeply and finely pinnatifid, brilliant shining green on the upper side. It is, undoubtedly, one of the most elegant cool-house Ferns in cultivation. Native of New Zealand.

L. cycadoides.—With this noble species (which has been introduced to commerce during the present season by Mr. Williams, of the Victoria Nursery) I shall conclude my enumeration of this genus; it is a bold-growing, handsome, and very distinct Fern; the stem is stout, both crown and stipes being densely clothed with very large and broad, almost black, chaffy scales; fronds, pinnate, very thick and leathery in texture, dark green above, pale below. Native of South Africa.

Blechnum.

There is really very little difference between this genus and the preceding, the shape of the indusium, and the fact that the fertile fronds are never contracted, forming the chief distinguishing characters. The general treatment necessary for the species here introduced is the same as before named for the various kinds of Lomaria.

B. brasiliense.—Stem from 1 to 2 feet high, stout, the crown of plant and base of stipes clothed with numerous long, black, and glossy chaffy scales; the fronds are supported upon very short stipes, they are somewhat erect in habit, from 2 to 4 or 5 feet long, and about 18 inches broad, deeply pinnatifid, and bright green in colour; when young the fronds are beautifully tinged with rosy-pink. It is usually considered a stove species, but when not growing, it will stand uninjured in the cool house. Native of Brazil.

B. orientale.—This is still a rare species; stem stout, base of stipes and crown of plant clothed with long, shining, chaffy scales; fronds from 1 to 3 feet long, ovate-lanceolate in shape, pinnate and coriaceous in texture; pinnæ linear-lanceolate, from 3 to 6 or 9 inches in length, and pale green in colour. It is a beautiful stove species from the East Indies.

Leptopteris.

The species here described are usually known as Todeas, but as some authorities have separated them from that genus, on account of their thin and membranaceous fronds, I have here followed their example; at the same time, I am not satisfied that it is a sufficiently good case for generic distinction. The kinds here enumerated are all greenhouse or cool-house kinds, which require a close moist atmosphere to keep their fronds perfect. We have before alluded to these plants in our remarks upon Filmy Ferns, and recommended them to the notice of our readers as gems for the Wardian case; and, as young plants, for this purpose, they are certainly unequalled; during the past year or two, however, importations which have reached this country have revealed to us the fact that with age they build up stout and massive stems, and they must therefore also take their place amongst the sub-arborescent kinds.

L. Wilkesiana.—This species is apparently a plant of slow growth, and it must take a long time to attain to a height of 4 to 6 feet, which travellers and collectors assure us it does in its native habitats. The stem is slender, seldom much exceeding the dimensions of an ordinary walking-stick; the fronds vary from 1 to 2 or more feet in length, according to the age of the plant; they are broadly lanceolate, the pinnules being oblong-obtuse, dark green, and pellucid, yet not to the extent of the other species. It is a truly beautiful plant. Native of the Fiji Islands.

L. superba.—The stems of this plant are stout, the tallest we have seen being about 20 inches in height, bearing upon its summit a lovely crown of ovate-lanceolate fronds, which are of a brilliant sea-green, with the edges beautifully curled up. It enjoys plenty of shade and a close moist atmosphere. Native of New Zealand.

L. hymenophylloides.—The fronds of this species are more triangular in outline than those of the last-named plant; but, like it, the stems are very stout; fronds, pellucid and deep green, but devoid of the peculiar and distinctive character of *L. superba*, viz., the curled and crisp appearance of the segments. Native of New Zealand.

L. intermedia, as its name implies, is intermediate in appearance between *L. superba* and *L. hymenophylloides*; for, whilst retaining the ovate-lanceolate-shaped fronds of the former, the texture of the pinnæ is that of the latter; it also builds up a stout stem with age, but hitherto very few examples have been introduced. Native of New Zealand.

Diplazium.

One species only of this genus can be admitted into this enumeration, but it is a very handsome bold-growing plant. As a genus, *Diplazium* has very little to distinguish it from *Asplenium*, the chief character being the double sori, which are placed back to back upon the veins; but this is not always constant; they are all, however, well deserving attention at the hands of Fern lovers, especially the species here named.

D. arborescens, is a massive bold-growing plant, attaining a height of about 4 feet in old and well-grown examples; fronds, broad,

dark green, bipinnatifid with finely divided pinnæ, the stipes and crown being abundantly furnished with large chaffy scales, rendering it very effective. It should be grown in equal parts peat and loam with some sand added; it enjoys an abundant supply of water, and thrives admirably in the cool Fernery. Native of St. Helena.

Angiopteris.

Although the plants belonging to this genus and *Marattia* are not considered true Ferns, they, nevertheless, are sufficiently akin to be introduced into this enumeration. They are characterised by their gigantic rachises, which rise from between two thick fleshy appendages, and which ultimately build up a short stout and fleshy sub-arborescent caudix; the veins are simple or forked, and free. Sporangia biserial, sessile, opening by a slit on the inner side. They, are for the most part, native of swampy places in the Islands of the Indian Archipelago, although some have been found upon the mainland. For compost, use good rich loam and sharp river-sand, drain the pots well, and supply water abundantly; where sufficient space can be given to *Angiopteris*, they form gigantic specimens, and produce a truly tropical appearance.

A. evecta.—The fronds of this species we have seen nearly 18 feet in length, but it assumes all its proportions and beauty when they are about 2 or 3 feet in length; they are bipinnate; the pinnules of a lively bright shining green in colour. For planting on the border, or upon an island in the stove Fernery, it is admirably adapted. Native of many of the East Indian and Pacific Islands.

A. assamica.—Whilst resembling the preceding in general appearance, it is narrower and smaller in all its proportions, and does not so rapidly attain a gigantic size, which will render it more suitable for the majority of amateurs. Native of Assam.

A. pruinosa.—A noble growing plant, resembling *A. evecta* generally, but differing in having the under-side of the pinnules beautifully glaucous. Native of Java.

A. Teysmanniana.—This is also a very handsome plant; when mature, it reaches 20 feet in the length of its fronds; as a young specimen, however, it forms a beautiful object in the Fernery on account of the vivid green of the pinnules. Native of Java. Of this genus we have other forms, but they are not specially amateur's Ferns, and, therefore, we imagine the above will be quite sufficient to introduce in this enumeration.

Marattia.

These are closely allied to the preceding, and indeed resemble them in general appearance, but are more adapted to the wants of Fern growers generally, inasmuch as they never assume such giant proportions, and, consequently do not require so much space. Soil and treatment should be the same as recommended above for *Angiopteris*.

M. laxa.—In this we have a large bold-growing kind, which will thrive in a warm greenhouse. The fronds attain a height of some 5 or 6 feet; they are bipinnate, having broadly-lanceolate, dark green pinnules. Native of temperate regions of Mexico.

M. elegans.—An extremely fine ornamental species, having bi-tripinnate fronds, which attain a height of some 5 or 6 feet, the pinnules are rich deep-green in colour. Native of New Zealand.

M. alata.—With this species I shall bid adieu to this genus. There is no question that it is the handsomest of all as yet introduced to our collections. The fronds are bi-tripinnate, the pinnules small, the rachis, in addition, being beautifully winged, and the colour a soft pale green. It succeeds admirably in the cool-house when not in a growing state. When the young fronds are about to unfold, however, I have found it much benefited by a little extra warmth. Native of the West Indies.

Eupodium.

One species only represents this genus amongst cultivated Ferns, and it is very rare. As a genus, it differs only in having its clusters of exannulate Sporangia (synangia) set upon little stems or foot-stalks. Treatment same as for *Marattia*, but it must be kept in a warm house.

E. Kaulfussii.—This plant attains a height of several feet, and, saving in the peculiarity of its fructification, it very much resembles *Marattia alata*. It is an exceedingly handsome plant, and those who love the curious forms of the order, will reap much pleasure from it. Native of Brazil. G.

Evergreen Walls for Moist Stoves.—The back walls of these structures, whether lean-to or half-span, often present a very unsightly appearance from the great amount of moisture in the atmosphere rendering it impossible to keep any sort of wall clean, for any length of time. Even the usual plan of covering with

creepers is not always effective. The mode of furnishing which we adopt is both simple and effective, and gives us at all seasons plenty of Fern fronds for cutting; the only preparation required is to have the wall "wired" over as if for training trees on, except that the staples for holding the wire should be fixed so that there is a clear space of about 3 inches, which should be firmly filled with partly decayed turf and peat. Into this compost we insert any spare roots of Ferns suitable for cutting, especially Maiden-hairs and the *Pteris* tribe, with a few *Fittonias*, *Isolepis*, *Foliage Begonias*, &c., finishing off with little patches of *Lycopodium denticulatum*, about 6 inches apart, to form a ground-work. Keep the soil constantly moist by syringing, and in about six weeks there will be a wall of living green on which the eye will never weary in dwelling, and a most agreeable contrast to the bright foliage and flowers usually found in houses of this description.—JAMES GROOM, *Henham Gardens*.

HOYAS AS BASKET PLANTS.

Hoyas generally, that is the free-flowering kinds, make interesting pot plants, and they are also useful for training along the back walls of stoves, but, as regards the smaller growing species I know of no position in which they show themselves off to better advantage than when planted in hanging baskets. For this purpose, one of the prettiest of all is *H. bella*, a dwarf-growing plant of shrubby habit, having short thick oblong leaves about half an inch in length, and clusters of pure white star-like flowers with purple five-lobed centres, set, as it were, in frosted silver. These clusters of blossoms suspended, as they are, from slender branches are best seen when looked at from below. *H. Paxtonii* somewhat resembles the last, but has longer leaves drawn out to a point at the ends, and somewhat wavy at their margins. This species also flowers freely and makes a nice ornamental-basket plant. *H. longifolia* is another species that answers well for this purpose, and even the Wax Plant, *H. carnosa* and its golden-variegated variety may be grown in large baskets and trained around their sides. A stove temperature suits them best, and frequent syringings with tepid water aids them in making robust growth. B.

ORCHIDS IN FLOWER AT KEW.

This collection is now very interesting, the following, amongst others, being in flower:—*Sobralia macrantha* is bearing seven or eight of its great lilac flowers at the apices of reed-like stems 2 to 3 feet high; this is a good variety with a deep purple lip, and has the additional advantage of flowering on stems about half the usual length. A healthy plant of the true *Odontoglossum læve* bears a fine branched spike, but the flowers are not yet fully expanded; this plant is quite distinct from *O. Reichenheimii*, to which, however, it is closely related. A plant of *Dendrobium Dalhousianum* bears a small spike of flowers on a pseudo-bulb only about 18 inches in length; this is one of the finest and strongest growers of the entire genus, often producing growths from 4 to 6 feet in length, and it flowers from the last year's, or old, growth; this is the largest-flowered of all the *Dendrobes*, and is one of the most striking of all Orchids when in flower, each being nearly 4 inches across, the broad segments being of a cream-colour suffused with rose, while the great concave lip is hairy on the disc and blotched with blackish-purple. A plant of *D. Farmerii* bears several spikes of pearly-white flowers, the lip having a blotch of yellow at the base; this is a free-flowering and very variable plant both in habit and flowers; a specimen which bloomed in Messrs. Veitch's collection a week or two ago had a dense spike of bright rosy flowers, with an orange blotch on the lip, and the flowers were much larger than in the Kew specimen. There is one plant always in bloom at Kew—we might instance several—but the one we now allude to is *Epidendrum cochleatum*, the shell-lipped *Epidendrum*, and one of the first of Orchidaceous epiphytes, introduced to the Royal gardens. It is a variable plant, but some of its varieties are well worth growing, if only for its ever-flowering character. Its sepals and petals are of a pea-green colour, the concave lip being striped or shaded with dark purple or chocolate colour, and this is of remarkable richness when seen between the eye and the sunlight. *Cœlogyne ocellata*, one of the prettiest species in the genus, is blooming freely, bearing spikes of white flowers an inch or an inch-and-a-half across, and having a large blotch of lemon-yellow on its tri-lobed lip. This blotch of yellow is margined with a red or vermilion-coloured line, and the flowers

themselves are delicately scented. The large-flowered form of *Phalænopsis grandiflora* is still in bloom, as is also *P. rosea*, a plant rarely out of flower wherever it is grown. *Odontoglossum Alexandræ*, *O. Pescatorei*, and *O. nebulosum* are in flower, as are also several species of Lady's-Slipper (*Cypripedium*), besides many curious small-flowered species of terrestrial habit, no less interesting to the botanist than the showy kinds, while the entire collection never looked in better condition than it does at the present time, notwithstanding the many drawbacks a cultivator has to contend with in a public establishment, where visitors are continually opening the doors, thus causing the cold or chilly draughts so detrimental to this class of plants. B.

DIEFFENBACHIA BOWMANI.

THIS beautiful tropical Aroid is a native of South Brazil, whence it was introduced by Messrs. Veitch & Sons, of Chelsea, who named it, in compliment to its discoverer, the late Mr. Bowman. It is one of the finest Dieffenbachias in cultivation, having leaves about $2\frac{1}{2}$ feet long and a foot wide, blotched and spotted with very dark green on a pale green ground. The value of this class of plants is very great; for, wherever a stove temperature can be commanded, they may be grown with the greatest facility. Any damp corner will do for them; but, in order to have the varied colours of the leaves well brought out, they should be kept near the glass. A good fibrous loam and some peat, enriched with decayed manure or leaf-soil, makes a good compost for them; and it should be open and spongy, for Dieffenbachias like plenty of water; but stagnant moisture is ruinous to them. They also enjoy a moist atmosphere while growing, and free use should be made of the syringe at that season. If they grow lanky, as they are sometimes apt to do, the remedy consists in decapitating them and using the heads as cuttings, still retaining the stumps in the pots, and plunging them in bottom heat. Under this treatment, every dormant eye will start into growth, the one nearest the summit taking the lead; all the shoots in their turn may be removed with a small heel and used as cuttings. No one, therefore, having the convenience of a stove, need be without plants of Dieffenbachias, all the varieties of which are useful, and very ornamental when intermixed with flowering plants, or others having brilliant leaves. For window-gardening and table-decoration, this class of plants is sometimes used with good effect; but their durability under such circumstances is so brief, that, after all, they are, perhaps, best when kept in the stove. W. F.

Agave Ellemeetiana.—This smooth-leaved, or unarmed species, belonging to the spicate group, is just now bearing a stout spike of greenish-yellow flowers in the succulent house at Kew. The spike is fully 5 feet high, and very thick in proportion, while the flowers are the smallest we have seen on any species of this genus, the anthers being, on the contrary, very large in proportion to the size of the flowers. The flowers are geminate, or borne in pairs, and at the base of each pair is a long narrow, almost hair-like, bract. The spike on the large plant of *A. americana* close beside it, has pushed its stout spike several feet above the roof of the house. When first produced, this spike lengthened at the rate of about 3 inches per day, but the growth now is less rapid, seldom exceeding an inch.—B. F.

Showy Cactuses.—These old-fashioned plants are too often neglected; still, they are well worth general culture, either as greenhouse or window plants. They are easily propagated by means of cuttings, a piece of a plant placed in a well-drained pot of sandy earth, and not over-watered, being sure to grow; and, when in flower, there are few other plants that can rival them in brilliancy of colouring. It is almost impossible to kill them by any amount of ill-treatment, unless they are over-watered during the dull cold days of winter, at which period they should be dust-dry, as they are apt to rot off at the crown. They are properly named *Phyllocactus*, or *Leafy Cactuses*, in contradistinction to *Echinocactus*, *Hedgehog*, or *Globe Cactus*, and other globular or cylindrical species. When not in bloom, they can be stored away on any shelf near the glass, where they should be duly attended to throughout the summer, so far as watering is concerned. As window plants they have few equals, and are very generally employed for that purpose in country districts.

The following are distinct and beautiful:—*P. Corderoyanus*.—A fine scarlet or crimson, suffused with bright metallic-purple. The flower is 4 or 5 inches across, and is one of the most striking of the scarlet varieties. *P. Jenkinsonii*.—This bears a smaller flower than the last, of a bright scarlet colour, and not fully expanded. *P. Gordonianus*.—A large variety, with bright rosy or flesh-tinted flowers. *P. crenatus*.—This is a creamy-white variety, with large flowers, and contrasts well with the other deeper-tinted varieties.—J. P.

Pachypodium succulentum.—This, one of the most interesting of all ornamental plants, is now blooming in the succulent house at Kew. It has a swollen or gouty stem, not unlike a Swedish Turnip in external appearance, and from this spring, numerous horizontal or deflexed spinose branches, varying in length from 18 inches to 2 feet. These are again divided into little branchlets, at the apex of each of which is a tuft of narrow glaucous leaves and a cluster of pearly-white star-shaped flowers, each about three-quarters of an inch in diameter. These, being borne very profusely, are very ornamental, apart from the singular habit of the plant. It is a native of the Cape of Good Hope.—Hortus.

Ipomœa (Quamoclit) coccinea.—It may interest some of your readers to know that this plant is now growing freely as a climber in one of the plant-stoves at Kew. It has slender twining stems, set rather closely with elegant pinnate leaves of a dark green colour, the divisions reminding one of the teeth of a fine comb. It bears a vivid scarlet flower, and is very ornamental either with or without flowers. It does not require any great heat, indeed, it is almost sure to be attacked by red spider when grown in a high temperature. In America it is extensively used as a window plant, and deserves a fair trial for similar purposes in this country during the summer months.—B.

Clerodendron Thomsonæ.—This, one of the showiest of all stove climbers, is now in flower; we have it here trained up the rafters, where it forms massive wreaths of deep green foliage and clusters of white crimson-tipped flowers. It likes a rich, open, and well-drained soil, and should be regularly syringed every day when making its growth. Unless duly attended to every day with regard to moisture both overhead and at the root, it is liable to become infested with nearly all the noxious insects that plants generally are heir to, notably to mealy bugs and thrips. If these should put in an appearance show them no mercy, but syringe at once with strong tobacco-water or Fowler's Insecticide nearly double the strength recommended on the printed directions. Give them two or three doses a week until they are *non est*, as they soon spoil the appearance of foliage and flowers alike. If there is no room to plant it out, it readily accommodates itself to pot culture, and soon makes a fine exhibition specimen if liberally treated. Occasional doses of clear liquid-manure are beneficial when the pot becomes filled with roots, and the plant should be neatly twined round a globe or balloon-shaped trellis so as to show off its clusters of flowers to the best advantage. I can scarcely conclude without alluding to another member of the genus, *C. fallax*, an old crimson-scarlet variety, which blooms the first year from cuttings. This should find a place in every plant-stove, however small.—J. H., Sydenham.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Convolvulus Cneorum.—This is a dwarf shrubby free-flowering species, well worth more general culture than it receives as a pot-plant, either for greenhouse or for window decoration. Its foliage is of a silvery or glaucous tint, and the flowers are each the size of half-a-crown, of pearly whiteness, with a pale lemon centre.—J. H. S.

Philodendron crinipes.—This species is admirably adapted either for covering rockwork in a tropical conservatory, or for training over the moist back wall of a warm plant-stove. It is a quick grower, having dark glossy lacinate foliage a foot-and-a-half long by a foot or more broad, borne on long stout petioles of a reddish-purple colour. The most peculiar part about this plant is the slender filiferous appendages (like those of a Moss Rose bud) by which these petioles are thickly covered, giving them just the same appearance as if covered with fresh green Moss.—C. H.

Arctotis grandiflora.—This is not so often seen in cultivation as it deserves to be, especially as it may be readily propagated, and grows freely, either in a cool greenhouse, or when treated as a window-plant. It is of a shrubby habit, about a foot or 18 inches high, and has silvery grey or glaucous-tinted pinnatifid foliage, and rich orange flowers, which are not unlike those of *Gazania splendens*, or the rare *Mutisia decurrens*. It is a native of the Cape of Good Hope, and is one of the most showy Composites we have, each flower being about 3 inches high, and nearly as much across, when fully expanded.—A. S.

Sarsaparilla.—The plant from which this well-known medicine is prepared, is, in itself, one of the finest of all climbers for a plant-stove or warm tropical conservatory. Its leaves are of a deep glossy green colour, with irregular silvery blotches or markings. Each leaf is 9 to 15 inches long, by about 8 to 10 inches wide, broadly heart-shaped in form, and they have a fine effect when the rambling shoots are trained up the rafters or tied to trellis work. There are several other species of *Smilax* very ornamental, but the present species (*S. officinalis*) is by far the finest I have yet seen. It is now growing vigorously in one of the stoves at Kew.—D. R.

THE FLOWER GARDEN.

AUBRIETIAS AND OTHER SPRING-BEDDING PLANTS.

THE floral display in the spring flower garden is seldom very effective, nor is the garden itself very enjoyable during most seasons until after the middle of the month of March, so that its season is necessarily of comparatively short duration, and the period is already rapidly approaching when the present occupants of the flower beds must give place to their summer successors. This season, up to the present time, on account of its great drought, can hardly be considered as having been favourable to the development of spring flowers. The rainfall of the month of March was little more than an inch, while that of April was considerably less (viz., 0.69 inch). The

producing a display at a distance than any of the *Myosotis* family, whose great beauty can be best appreciated on a closer inspection. *Aubrietia Campbellii* may be readily increased by cuttings; and *Græca*, *purpurea*, &c., by divisions or by seed, which should be sown under glass about the middle of March or beginning of April, and afterwards pricked out in beds in the open air about the middle of May, when they will be in a fit state to be planted in the beds of the parterre as soon as the summer bedders are removed. Marginal lines of *Echeveria secunda glauca* have suffered very considerably during the last winter, and can hardly be depended upon for spring bedding. Many succulents, however, are all that can be desired for this purpose, such as *Sempervivum californicum* or *calcaratum*, together with *S. globiferum*, *S. rubicundum*, &c., and the beautiful *Sedum acre aureum*, *elegans*, *Sieboldii*, &c.; also the well-known *Cerastium tomentosum*, *Santolina incana*, and

Dieffenbachia Bowmanni (see p. 414).

water-springs are now exceedingly low, and water, in many parts, is becoming scarce. During the last fortnight cold east winds have prevailed, accompanied by hot sunshine, which has caused the early Tulips, &c., to go out of flower earlier than usual, and has much impaired the beauty of beds of Pansies, Primroses, Polyanthuses, Violas, Wallflowers, &c.; and a severe frost on the night of April 29th—amounting to 8°—sadly blackened and nearly destroyed fine beds of the beautiful *Myosotis dissitiflora*, &c., as well as killing all the young shoots on Walnut trees, and severely injuring many early crops of culinary vegetables. Most of the varieties of *Aubrietias*, however, appear to have the power of resisting cold as well as drought in a great degree, and beds of such species as *Græca* and *Campbellii*, margined with the golden-feathered *Pyrethrum* and the golden-striped *Thyme*, are still exceedingly effective; indeed, the *Aubrietias* appear to be among the very best of spring-blooming bedding plants, and are much more effective in

Veronica incana, with many of the *Saxifrages*, such as *S. Andrewsii*, with its neatly serrated foliage, *Aizoon longifolia*, and *umbrosa*, with its various varieties, &c. P. GRIEVE.

CULTURE OF PRIMULA CORTUSOIDES AMCENA.

WHAT may be termed the original type (*Cortusoides amcena*), has rosy-magenta flowers with a white centre; then there are such varieties as *lilacina*, or, as it is sometimes called, *striata*, the flowers marbled white and lilac; *alba*, with pure white blossoms; and a large form of *amcena*, called *grandiflora*, with blossoms of greater size, deeper in hue, and not so white in the centre. Soon after this fine Primrose was introduced there was a large variety of it called *grandiflora*, the blossoms of which took a cupped shape, greyish-white in the face of the flower, the reverse of the petals being deep rose. As this is rarely if ever seen now, I suppose it has nearly gone out of cultivation. The large-flowering rosy-magenta form, the lilac or striped variety, and

the pure white one, are all distinct, and well merit cultivation. It will bloom well in the open ground, but the flowers are liable to be much injured by rain and winds, which soon detract from their beauty; when grown well in pots under glass it is capable of a high stage of development, and the flowers are numerous, large, and well-coloured. The plant is easily propagated or increased by root-divisions. It has the peculiar habit of throwing out creeping roots which form crowns, and so furnish plants; when the plants begin to go to rest at the end of the summer, these young plants should be removed and potted singly into small 60-sized pots, well-drained with crocks, in a free open compost of turfy loam and leaf-mould. These should be wintered in a cold frame and kept slightly moist during the winter. - The parent plant, after the crowns are removed, should be left in the pot till growth sets in, when it should be re-potted without shaking away much of the old soil. It is a plant that is fond of establishing itself and remaining undisturbed. When potted, the plants should be afforded pot-room according to their strength; the pots should be drained and a little Moss placed over the drainage to prevent the soil from getting down among the crocks, and preventing a free passage of the water. Good mellow loam, leaf-soil, and some well-decomposed manure, will form an excellent compost, and the crowns of the plants should be quite buried. Pot the plants moderately firm, and do not give them any water for two or three days; when the plants grow freely they should be watered abundantly. It is a good plan to allow the plants to remain in the same pots at least two seasons without shifting; they will flower much more freely in consequence. In the spring of the second year, some of the top soil should be removed, and some good rich soil added, and, as the plants begin to unfold their buds, a little weak manure-water should be given. What the cultivator should aim at is a vigorous healthy growth, or else the plants are liable to be infested with red spider. During summer the plants should be syringed daily, to keep this pest in check. If shaded from the effects of hot sunshine the bloom will be prolonged, and an excellent decorative effect will be maintained for many days.

R. D.

SAXIFRAGES.

By J. C. NIVEN, Botanic Gardens, Hull.

The Mossy Group. (Concluded from p. 371.)

S. obscura of Godron bears considerable resemblance to the *Cæspitosa* group; it is, however, more procumbent and lax in its general habit of growth, its leaves are not so compactly arranged, but distributed in a somewhat scattered manner along the barren shoots. They are pedatifid, seven-lobed, the lobes deeply divided and linear, pointed but not mucronate; the whole suffused with soft irregular hairs, which assume a dense interlacing character on the foot-stalks. The flowers are white, produced on short foot-stalks. In the petals we have, perhaps, one of the most marked peculiarities that this species possesses, each petal being distinctly incurved on the margin, as to the lower half; this character, though not alluded to by Engler, appears to me to be very constant. This species is only recorded as occurring in the Eastern Pyrenees, but may possibly have a much more extended range, as it might easily be passed over as one of the forms of *Cæspitosa*.

S. ajugæfolia.—This is by no means the happiest of Linnaeus's specific names, as the ordinary forms of the *Ajuga* or "Bugle" with which most people are familiar, have large entire leaves. There is however, a small section of annual plants, in the genus of which the *Chamæpitys* is the type, and this particular section he must have had in view when he gave the name; here we find the leaves trifid with linear segments in place of entire, and certainly bearing a fair resemblance to this species of Saxifrage. In habit of growth it is decidedly a rambling plant, producing long trailing shoots. The leaves are deeply divided into three lobes, each lobe being notched at the point, the divisions are wider apart than in the previous species, and the whole plant less hairy. The flowers are less profuse, and the petals narrower, with a short claw; the marginal incurvature being altogether absent. This also is a Pyrenean plant, on which range it appears to have a pretty extended distribution.

S. aquatica of Lapeyrouse and *adscendens* of Vahl are synonymous; both names are appropriate; the former, which I adopt, indicates the medium in which it grows, the latter the habit of its growth. The ascendent character is, however, more or less general through this section, whereas the aquatic one is almost peculiar to this species; hence the reason for its adoption. The marshy Saxifrage produces its leaves in large densely-arranged rosettes; individually, they are divided into three lobes; each lobe again has three somewhat broadish and blunt sub-divisions; these divisions, however, do not extend more than half the depth of the blade of the leaf, the foot-stalk becomes dilated or sheathing at its base, and the whole is covered with short downy hairs, slightly viscid in the early stages of

growth. The inflorescence is leafy, many-flowered, and, when growing vigorously, is said to attain a height of 15 or 18 inches. The cauline leaves are much more sharply cut than the radical ones just described. All the flower-stalks are thickly covered with a dense glandulous pubescence. The capsules are inflated, and said to present a very marked appearance after the blooming period is over. This plant, when growing in a favourable position, say at the margin of a water rill, is readily distinguished by its free, luxuriant, and rambling growth; if cultivated under the same conditions as the majority of the previous species in this section it becomes stunted and starved, its true character being altogether suppressed. It is a native of Corsica and Sardinia, where it affects the margins of the high mountain streamlets. Before completing my remarks on this species let me note that we have for years cultivated a plant under the name of *adscendens* which is nothing more than a form of *hypnoides*.

S. irrigua of Sternberg, and also of the "*Flora Taurica*," is removed from this section by Engler, for reasons which are of so technical a character, that I need not here state them. Suffice it to say, the general aspect of the plant claims a place among the major forms of the mossy group; and, seeing that it has been considered by some as a variety of the preceding, we must give it its true family position. As a species, it is perfectly distinct, were it in no other respect, in the fact that it is little more than biennial, and does not produce those creeping stems that form the succeeding year's rosettes. Grown from seed, the first season it develops a mass of much-divided long-stalked leaves, covered with long, soft, lax hairs; in the second year, an erect, much-branched, and leafy flower-stem rises to a height of 12 or 15 inches, remarkable, also, for the abundance of long hairs, and general upright habit of all the secondary branches. The petals are white, narrow, and supported on short stalks, thus giving the flower a stellate character. The capsules, as in the preceding, are inflated, and, on the maturity of the seed, the whole plant dies. It is a native of the Caucasus and Armenia. Though, in its young state, it is very sensitive of moisture and damp, and liable to rot off therefrom, when it is in bloom, it may be almost said to be aquatic, so happy and vigorous is it when abundantly supplied with root-moisture.

S. Schraderi of Sternberg is a species which, though wholly omitted by Engler, has good claims to recognition; most Saxifrage cultivators must have been familiar with the plant for years. It is of a somewhat slender wiry growth, producing its lateral stems (procumbent they can hardly be called) so freely that it soon forms a large patch on a rockery, conspicuous for the red-coloured flower-stalks, which are extremely beautiful, especially before flowering takes place. The lower leaves are divided into five or seven very narrow fleshy segments, each division terminated with a rigid mucro or point. The stems are branched from the base, about 12 inches high, the lower leaves thereon being trifurcate; the upper ones entire; the whole plant is devoid of hairs or glandular pubescence. The flowers are numerous, of a very pure white, which contrasts beautifully with the almost coral-red floral stems. It is recorded in Loudon as a native of Spain, but what part I cannot say. We have a form of it slightly more slender in growth, and which I recognise as a variety under the title of *leptophylla*.

S. ceratophylla of Dryander.—The Stag's-horn Saxifrage is such an appropriate descriptive name of the plant that I do not feel at all inclined to endorse Engler's substitution of *Schraderi* name trifurcata, which would in truth be a much more appropriate one for the preceding species, where the trifurcate stem leaves are very conspicuous. The Stag's-horn character is represented in the individual lobes of the leaves, which are somewhat broad, each one notched more or less deeply into five irregular divisions; the foot-stalks are between 1 and 2 inches long, dilated at the base, thus giving a large and lax character to the lower growth of the plant. The panicle is much branched from the bottom upwards, the lower secondary branches being long; the whole plant is glabrous. It is a free grower, with noble panicles of pure white flowers, which rise from an irregular cushion of notched and divided leaves. This species is sometimes grown under the name of *S. paniculata*; at one time I thought this had sufficient character to be considered a variety, but, after three years' culture I find it is nothing more than a synonym. Here I cannot resist adding another synonym I picked up at one of our grand national exhibitions a few years ago, viz., *S. stag's-horniana*! The exhibitor modestly withheld the authority for the name, but, judging by the general nomenclature of the group, I think I may safely consider it to have been original. The plant is a native of the central mountains of Spain.

S. Willkommiana of Bourgeau is the name under which this very distinct species of Saxifrage made its *entrée*, some three or four years ago, into cultivation in this country. I, therefore, prefer to retain it rather than Boissier's name, *Canaliculata*, though I admit, at once, that his name is most appropriate. To this plant the title

Stag's-horn Saxifrage would be equally appropriate as an English name, as *Stag's-horn* was to the preceding; here we have a plant of straggling slightly woody habit, with large leaves divided towards the margin into five or seven unequal oblique divisions, the great portion of the leaf being entire, narrowing gradually into a sheathing petiole, and deeply channelled through its upper surface, slightly viscid below, thick and leathery in substance, and altogether glabrous. The inflorescence does not possess the same magnitude in development as might be expected from the size of the foliage and the general appearance of the plant; moreover, the flowers are comparatively small, and supported on very short foot-stalks; in the bud they are prettily tipped with pink. It is a native of the mountains in the province of Leon and also the inland mountains of Southern Spain.

S. pentadactylis of Lapeyrouse is a dense, rigid, compact-growing plant, whose height, including blooming stem and all, rarely exceeds 6 or 7 inches. Its leaves, besides the three primary subdivisions, have each division again notched into three, the points of each being rigidly mucronate and slightly reflexed; hairs are absent, but the upper surface of the leaf is covered with glands that excrete a viscid fluid. In autumn and early spring the presence of these glands is indicated by tiny white dots, which give the plant a very pretty appearance, something of a fawned silvery character. The leaves and the divisions thereof are deeply channelled. The inflorescence is small, but the flowers themselves are of snow-white purity. The several distinctive features I have enumerated will at once indicate that it is a most desirable species to cultivate. It is a native of the Eastern Pyrenees, and has long been in cultivation, but is not so frequently met with as it ought to be.

S. geranioides of Linnaeus is a good distinct species, of slightly shrubby and rambling habit of growth. Its leaves are reniform in general outline, three-lobed, the centre one being the smallest, and divided into three terminal teeth. The lateral lobes are irregularly notched in a pedate manner; the foot-stalks are long and spatulate, and the whole covered with a dense arrangement of short hairs, which are glandular in the young state. The flowers, which are produced in simple panicles, with one or two secondary branches, are clustered together in a corymbose manner, owing to the shortness of the foot-stalks; the petals are narrow, gradually tapering to the base. At this season of the year, the whole plant yields a balsamic odour, very similar to some of the species of *Cistus*. So volatile is the essential oil given out by the glandular hairs, that, on passing a large patch after a shower of rain, the atmosphere appears to be laden with it. There is a variety to which the title *ladanifera* has been given by Lapeyrouse, in the description of which he alludes to the presence of numerous purple balsamic globules on the leaves. Were it not for the absence of colour, I should be disposed to refer our present plant to the variety, rather than the true *Geranium-leaved* species, as, in Linnaeus's description of it, no allusion whatever is made to the balsamic odour. Most probably his description was made from a dried specimen, in which case this special character would have vanished. The plant, however, is admirably adapted for overhanging a broad ledge of rock, which its free growth will soon cover, and where it will flourish far away from its original root-hold for years. It loves a bit of shade, and, in this respect, is exceptional in this section. It is a native of the Pyrenees. There is also some old tradition of its having been found in Britain, but to this statement we must append—doubtful.

S. Maweana, introduced from Tetuan, in Morocco, where it was discovered by our friend Mr. Maw, of Benthall Hall, and named after him, is of too modern date to claim a record in Engler's enumeration. It is, unquestionably, tolerably closely related to the previous species. The leaves are, however, more entire and less reniformly pedate, more fleshy, and devoid of the downy pubescence. One marked peculiarity consists in the presence of dense hard leaf-buds in the axil of each leaf. The flowers are large, nearly three-quarters of an inch across, not unlike the old *granulata*—but produced in lax panicles—the stalks being hairy, as also the calyx, and the whole flower-stem softened with a purple glandular dot. The buds, before expansion, are drooping. As I said before, it is a native of Morocco, where it grows on the Beni Hosmar range of mountains. It would appear that the solitary buds to which I have alluded, are an admirable provision of Nature—whereby, in an arid climate, under an almost tropical sun, the plant is enabled to retain its vitality through the hottest season of the year, when its foliage becomes completely withered up—but with a return of moisture, green leaves are developed from these fleshy buds, and soon flower-rosettes are formed; this peculiarity—to which I have before alluded under the title of summer hibernation—is peculiar to this species alone, but is likewise characteristic of the next one, and also of another charming little species, also introduced by Mr. Maw, which is just now coming into bloom; and which, though perhaps not so showy, will, I suspect, be found worthy of a name—to this I may, possibly,

have occasion to refer, before I bring my series of articles to a close.

S. globulifera of Desfontaines, is a dwarf, somewhat hard, prostrate plant. The leaves are cuneate, irregularly seven-lobed, with a scarious margin, of a light yellowish-green, springing from coral-red stems, and each one containing in its axil a hard compact bud, similar to those described in the preceding species. The flowers are small, produced in a lax corymbose panicle; the calyx is covered with short glandular hairs. It is a pretty and distinct species; both it and its variety *gibraltarica* are natives of the South of Spain and North Africa. I have for some years cultivated plants under the two names, and consider them both referable to the typical species *globulifera*.

TREATMENT OF ALTERNANTHERAS.

The *Alternantheras* are mostly indigenous to South America, and belong to the natural order *Amarantaceæ*. Many of them are now well known, and are found to be exceedingly useful as decorative plants in the parterre during the summer months. The delightfully ornamental-foliaged species known as *Alternanthera amoena*, is, perhaps, the most beautiful and delicate of the family. It is, nevertheless, of comparatively easy culture, although it is found to be somewhat difficult to induce it to grow, or to "make wood," sufficiently early in the season for the purpose of propagation. The following method of treatment has, however, been found to be generally successful. Early in the autumn, or before the plants have been injured by frost, a few plants are removed from the beds and planted, not too thickly, in store pots or pans, and, during the winter months are kept near to the glass, in a tolerably high temperature. About the middle of April (which is sufficiently early to commence the propagation of this plant), these store pots are placed in a close moist propagating-case or under hand-glasses, when the plants will soon begin to grow with considerable rapidity, and, by keeping the interior of the propagating cases saturated with moisture, they will emit abundance of aerial rootlets from the stems and at the base of each little shoot, and these, when taken off and inserted as cuttings, root into the soil in the course of a very few days. The soil used should be a mixture of river or silver-sand, and finely-sifted leaf-soil, and the cutting pots should be well drained. From a few store pots of this plant, treated in the manner described, it is found that a very considerable stock can be produced by the first week of June, which is quite early enough to plant them in the flower beds. Previous to being planted out, the plants should be, of course, gradually inured to the open air, but should never be potted off singly, nor removed from the store pots until they are about to be planted in the beds. When they are taken from the store or cutting pots, each plant is generally found to retain a little ball of the soil, held together by numerous fibry rootlets. The plants should be at once planted in the beds tolerably close together, in order to produce immediate effect, watering them well as the work proceeds, and if the weather is at all dry this should be frequently repeated. Wherever carpet-bedding is extensively practised, the various varieties of *Alternanthera* are found to be quite indispensable. A variety which promises to be an improvement upon even *A. amoena* has been recently introduced under the name of *A. amoena spectabilis*. It appears to be equally robust in its style of growth as *A. magnifica* and *A. paronychioides*, and attains to a similar height, while its beautiful magenta-rose leaf colouring is quite equal to that of the old variety, *A. amoena*.

P. GRIEVE.

CULTURE OF THE PETUNIA.

The *Petunia* may be raised from seed, and selected and named varieties may be propagated by cuttings. If the plants are required to be large and vigorous when planted out, so as to yield flowers at once, sow the seed in pans in August, and put them on a shelf in the cool shady side of a greenhouse, covering the pans with pieces of glass, and shading from hot sun. The soil must be kept moderately moist. As soon as the plants are large enough to handle with safety, let them be potted singly into thumb-pots, and kept close and shaded in a warm house till they make root, and then shift them into small 60-pots to winter there. If they are placed on a shelf near the glass in a greenhouse, and kept moderately dry, they will bear a little frost without injury. It is only those, however, who have but little convenience for raising seeds in early spring in

warmth that need trouble to raise Petunias at the end of the previous summer and preserve them through the winter. Those who have a brisk heat at command should sow the seed at the end of February, and pot off as directed, and grow on into nice strong bushy plants; use a soil made up of fine loam, leafy soil, and some silver-sand. In the flower garden Petunias can be employed during the summer with great advantage. A bed of mixed seedlings is a very attractive sight when in full bloom, presenting, as it does, such a number of varying hues of colour—from deep purple-crimson flowers, down to white flowers handsomely varied and striped with rose. Seedling Petunias are pretty certain to make vigorous growth, hence the necessity for planting them in rather poor soil. Petunias are often employed to form dense masses of colour, and beds of particular varieties are employed, the plants being raised from cuttings. In all cases of using Petunias in the flower garden it would be well to raise the plants from cuttings; they do not grow so strongly, nor do they seed freely, and thus the energies of the plants are directed to producing flowers. A purple-crimson self Petunia forms a fine mass of colour, and a silvery-leaved plant is generally used as an edging. If a deep-coloured Petunia and the old variegated Mangle's bedding Pelargonium be mixed together in a bed, the effect is very charming indeed. In damp situations it will often happen that during wet weather in late summer the plants will damp off and decay. But Petunias are also excellent plants for the decoration of the greenhouse and conservatory when grown in pots; and then there is scarcely a horticultural exhibition held now, large or small, at which prizes are not offered for Petunias in pots. In some parts of the west of England, wonderful examples of Petunias are grown for show purposes. They are put into large pots, and the plants tied out to sloping oval wire frames, by which means the flowers face all one way, and quite a dense surface of flowers is thereby obtained. If some plants are grown on into 48 and 32-sized pots, and pinched back for a time, to form nice pyramid-shaped plants, they soon become covered with flowers, and remain in bloom for a long period. They should be kept well watered, for they speedily suffer if allowed to become dry at the roots. Petunias are also well adapted for growing in stone vases and baskets, as they hang down over the sides, and have a charming effect. Fine strains of striped and blotched Petunias are now so general, owing to the improvement that has been effected in this charming flower of late years, that seed can be had from any seedsman. The earlier flowers nearly always come self-coloured, then they break into pretty striped forms that are most effective when mingled in beds. I have always regretted the banishment of the pleasant Phlox Drummondii from our gardens. In some old-fashioned places, it is never absent during the summer months, and it is always a welcome guest in the floral circle. The seed should be sown about the first week in March in shallow pans or boxes, using a light rich soil, and placing the seeds in a nice warm and rather moist temperature. As soon as the plants can be handled without injury, it is a good plan to prick them off into boxes, or on a bed in a warm house, in a temperature of from 50° to 60°. They soon make growth, and, as the weather gets warm out of doors, the boxes should be placed out in the shade to harden the plants. Those growing in a bed should be again transplanted to a prepared bed in a cold frame, and kept covered for a few days, and hardened gradually. When the plants are from 3 to 4 inches high they should have the main shoot pinched out; this induces them to make a lateral and bushy growth, and greatly assists the prolongation of the period of flowering. The soil in which the plants are to grow should be rich; an abundance of decayed leaves suits the Phlox well. The bed should be in a position fully exposed to the sun; as long as there is a good moist soil at the roots they will not be injured in the hottest bright weather. Quo.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Daffodils.—It may not be generally known that Daffodils do well planted in fields, which are not broken up, and to which cattle have access. I am acquainted with batches of them (and they look well every year) where cattle are constantly grazing, and yet they do not even tread upon them. On lawns, too, they have a pretty effect.—H. M.

Arabis rosea.—Although this novel form of a well-known *Arabis* was introduced into this country from Calabria in 1832, it is yet most rare. I have inspected hundreds of gardens of late years, and never met with it until a few days ago. It has a less robust habit than *Arabis albida*, but is a stronger grower than the *Aubrietias*. It blooms from March onwards, the blossoms being rosy-pink in colour, and it will, doubtless, make a capital carpet plant for early beds.—D.

Collinsia violacea.—This variety, introduced a few years ago by Mr. Thompson, of Ipswich, is not yet generally known. It is much dwarfer than the old *C. bicolor*, is comparatively hardy, and blooms after standing the winter in the open ground, about the third week in April. This *Collinsia* may be recognised by the colour of its flowers, which have white upper petals, the lower ones being bluish-violet. It makes a capital spring bedding plant, and Mr. Thompson considers it to be the best of all the family.—Q.

GARDENS OF LE PETIT TRIANON, VERSAILLES.

BEFORE the completion of the vast Palace of Versailles, Louis XIV. was already becoming tired of its monotonous splendour, and determined upon the creation of a lesser palace (since known as the Le Grand Trianon) in which he could escape from the irksome and *quasi* public magnificence of the greater structure. His project was imparted to Mansaart, the court architect, who undertook to create both palace and gardens with the least possible delay, and who made use of fully as much stone in the creation of the garden as in the erection of the palace, which, though consisting only of a ground-floor, or *rez-de-chaussée*, is yet, after a fashion, a repetition of the uninteresting style of the greater structure. Neither the palace of the Grand Trianon nor the gardens, so called by a somewhat inappropriate figure of speech, would have been mentioned in this article but that they form such a singular contrast to those of Le Petit Trianon, which were laid out and planted in a happier period of French taste in garden making.

Le Petit Trianon, constructed at a somewhat later period than its greater neighbour, was intended to be much smaller and less pretentious than Le Grand Trianon, and more calculated to afford the means of greater privacy; as a *regal casino*, it is in no way remarkable for beauty of any kind; but the gardens, which were planned and planted at a later period, in the style of a romantic kind of landscape gardening, at the suggestion of the unfortunate Marie Antoinette, instead of exhibiting the stone formalisms of the gardens of the greater Trianon, in which vegetation, either arboreal or floral, played a very secondary part, were, and are still, as we shall see, extremely pretty. Louis XV., at the instigation of the Duke of Aven, had caused a botanical garden to be laid out between the two Trianons, which subsequently became the scene of the important studies of Bernard Jussieu, whose system of botany, known as the natural system, for many purposes has superseded the artificial arrangement of Linnæus; and the trees then planted formed a kind of foundation for the laying-out of the pleasure-garden as it now appears. To carry out her special views, the young queen employed M. Mique, an artist whom she had appointed her special architect, and also the clever painter, Robert. She combined the talent of the two, in order that the hard lines of architecture should not predominate; and we find that this mingling of the two arts was highly advantageous; M. Robert insisting with the queen that, in a "garden," foliage, water, and paths undulating with the play of the soil, or the contour of the lake, combined with appropriate rustic buildings, should be the leading features. The architectural adjuncts, of a necessarily formal kind, were to be few, and grouped with foliage in such a way as to soften the hardness of their lines, as is seen in the pretty Temple of Cupid, figured in a former number of THE GARDEN.

A pet idea of the young queen was, not only the creation of a partially wild landscape-garden, but also the introduction of many of the ordinary features of humble country life, such as a rural village, a dairy, and a mill. These were accordingly constructed from the painter's, rather than the architect's, point of view, being pictures made with real trees, sketch-book cottages, a fanciful mill, a dairy, and a rude bridge, all designed by the painter Robert, and carried into execution by M. Mique; the cottages being, at the suggestion of the queen, in the style of Swiss *châlets*. Here it was that the beautiful young Austrian princess, habited as a shepherdess, or, at all events, in silk and lace attire, imitating, in general form, a rustic costume of more homely materials, assisted in milking the cows, carrying the milk to the dairy, superintending the churning; fancying that she had discovered the true secret of rustic simplicity and happiness, and enjoying her discovery accordingly. When we call to mind that this pretty little queen was the personage who wondered how it was that people could be starving in Paris while they could buy delicious Raspberry tarts at the pastrycooks, for two *sous*, it is not difficult to imagine that the graceful mock rusticity she had created should appear to be almost the very reality itself, especially as she felt so happy in throwing off the shackles of royalty while playing at rustic life among the bosquets of Trianon. Another of the enjoyments of Trianon, not quite so consistent with rural life as milking and churning, was the performance of private

GARDENS OF LE PETIT TRIANON, VERSAILLES.

theatricals in the palace-casino, as was the custom in French country houses at that time; the *comédie de château* being one of the favourite amusements of the *vie de province*. Here, in fact, was enacted—the Queen and the Comte D'Artois, afterwards Charles X., taking leading parts—Beaumarchais' celebrated comedy, "The Barber of Seville," with the author himself for the stage-manager. One cannot wonder that Charles X., when driven from his throne by the revolution of a single day, lingered a few hours in the gardens of the Petit Trianon, recalling sweet and bitter memories, before hastening to the frontier and quitting France for ever.

The young trees planted by Marie Antoinette, and those previously established during the reign of Louis XV., are now venerable with age, and, during the summer and autumn, throw the greater part of this exquisitely-pretty pleasure garden into a soft and pleasing half-light, which greatly adds to its charm. The annexed illustration represents the dairy, with its latticed windows and thatched roof, and its irregular walls, more than half concealed by a heavy mantle of Ivy and other climbing plants. The lofty trees, towering high above it, give it somewhat the air of a woodman's hut nestling deep in the bosom of a forest, the partial gleam of sunlight which the artist has thrown upon it adding to the sylvan effect. As it stands at present, the dairy and its surroundings offer a good model to a landscape gardener about to erect labourers' cottages on a large estate, with instructions from a tasteful proprietor not to allow them to become spots or disagreeable excrescences in the domain, but to blend with the surrounding scenery in a natural and artistic manner. Of course it is not recommended to make literal and slavish copies of the scenery of the Petit Trianon, but merely to study it and take in the general character of its beauties, as a young painter, after gazing steadfastly upon a work of Raphael, might instinctively infuse into his next picture somewhat of the ineffable grace that distinguishes the work of that great master.

Jussieu has left his footprints in the charming garden of the Petit Trianon, in the rare and beautiful trees that still flourish there, most of them (planted in 1764) being now in their prime, and some of them the finest specimens known of their kind. The Cypress of Louisiana (*Cupressus* or *Taxodium distichum*), with its remarkable roots which exhibit their singular forms partially above the ground, often rising, in their native marshes of Louisiana, to the height of 6 feet, is one of the fine trees alluded to. Many of them are very interesting now on account of the splendid growth to which they have attained. The Weymouth Pine, for instance, and a great variety of American Oaks; while a Willow-leaved Oak (*Quercus salicifolia*), has attained a height of above 90 feet.

Many trees, of recent introduction, have since been added to the woods and gardens of Trianon, such as the Wellingtonia, the Araucarias, the Himalayan Cypress, and others. The flower-garden, established, in 1850, by M. Charpentier, has much interest for botanists and all lovers of horticulture; the collection of Rhododendrons and Azaleas being magnificent, as well as that of other bog shrubs, and also the most remarkable novelties in herbaceous plants; which are invariably procured with the least possible delay, and, in most cases, cultivated with unusual success. There are also some remarkable trees in this part of the grounds, especially a magnificent pyramidal Oak, a Montezuma Pine, and a *Pinus Lambertiana*, which last is so vigorous that it promises rapidly to attain its native growth of 100 feet or upwards.

H. N. H.

THIS year the budding of the Oak is far in advance of that of the Ash. The tradition is, if the Oak gets into leaf before the Ash we may expect a fine and productive year; if the Ash precedes the Oak in foliage we may anticipate a cold summer and unproductive autumn. Referring to "Cassell's Dictionary of Phrase and Fable" we find that in the years 1816, 1817, 1821, 1823, 1828, 1829, 1830, 1838, 1840, 1845, and 1850 the Ash was in leaf a full month before the Oak, and the autumns were unfavourable. In 1831, 1833, 1839, 1853, 1860 the two trees came into leaf about the same time, and the years were not remarkable either for plenty or the reverse; whereas, in 1818, 1819, 1820, 1822, 1824, 1825, 1826, 1827, 1833, 1834, 1835, 1836, 1837, 1842, 1846, 1854, 1868, and 1869 the Oak displayed its foliage several weeks before the Ash, and the summers of those years were dry and warm, and the harvests abundant.—*Daily Paper*.

THE ARBORETUM.

TREES AND SHRUBS WITH VARIEGATED LEAVES.

At the present day, in gardens, large and small, we make groups (regular or irregular in form) of trees and shrubs with variegated foliage, arranged in straight lines, or in zones, and in positions suited to the height of each subject. In all the plantations which we have superintended for some years past, we have introduced one or more groups of this kind even in gardens of small extent, and always with great success, as this mode of arrangement accommodates itself to grounds of all varieties of size and form. In order to succeed well in plantings of this kind, it is important to have a knowledge of the materials employed, and to take into account the effect that will be produced by the different modifications of which trees and shrubs are susceptible in their height, shape, and even colour, according to the mode of culture and training to which they are subjected. In order to be complete in our instructions on this important question, it will be necessary to describe the trees and shrubs which may be used in compositions of this sort, and to make some remarks on the mode of training and propagating them, as both these operations modify the use of this or that tree or shrub. Lastly, we shall have to point out what positions, relatively to each other, these shrubs can, or ought to, occupy, in order to produce the desired effect. These practical instructions will be found more useful than a general dissertation, from which the reader would have to draw his own inferences, at the risk of deceiving himself, or arriving at imperfect conclusions. We have no intention of putting forward here a complete catalogue, or a treatise on culture, but simply a few notes which we have abridged as much as is consistent with an intelligible exposition of the subject. We shall conclude the article by giving some examples of combinations or groupings, which may suggest to our readers other arrangements, varied according to individual taste.

Descriptive List of Subjects.

Acer Negundo foliis albo-variegatis.—This handsome tree is pretty generally known. It may be employed in various ways; grown in bush form on its own roots, or grafted close to the ground on a stock of the plain-leaved variety, it forms handsome bushy specimens which may be used in combinations of all kinds. It may also be used to form the outside margin of groups which have been already planted in the ordinary way, with variegated or plain-leaved trees or shrubs. Grafted as a half-standard at various heights, it can be employed in groups planted with regularity, and consisting of trees or shrubs arranged in an order graduated according to the stature of each. If a rather tall half-standard is required, it should be grafted on a stock of *Acer californicum*. A group formed exclusively of this variegated Maple, grafted as tall standards and half-standards, with purple-leaved or deep green-leaved shrubs planted among them as underwood, presents a most splendid effect. Upon the whole, we shall not exaggerate in saying that, for our present purpose, the white-variegated Maple is, indeed, one of the most valuable subjects—we would say, the *pièce de résistance*, if this fine tree were not too handsome, airy, and graceful to merit the epithet.

Acer platanoides fol. aur. marginatis.—A handsome, new, and, as yet, rare variety, with fine large leaves, the margin of which is edged with a broad border of a handsome yellow. When it becomes more plentiful, it will do good service in forming contrasts of colour. It may be grown either as a bush or as a standard. When cut back to the ground it speedily sends up a fresh young growth.

Acer polymorphum var.—We are somewhat shy of mentioning this handsome Japanese species, with its numerous varieties, *atropurpureum*, *palmatum*, *palmatifidum*, *rubrum*, &c., because they are not within the reach of everyone's means. We hardly know anyone, except the honourable President of our Circle, M. Edm. de Ghellinck de Walle, who (in view of the expense) has not withstood the desire of possession which tempts all true amateurs at the sight of these magnificent trees. In his large and splendid park we have seen a superb group, single young specimens of which cost as much as £8 each. One great merit of these trees is that, contrary to what might have been expected, they stand our winters very well.

Acer Pseudo-platanus fol. aur. et arg. var., &c.—Of the Sycamore there are several varieties with richly variegated leaves, which well deserve to be introduced into plantations, arranged in zones

of large extent.* What would not be the effect of these trees in an avenue, planted as tall standards, alternately with subjects of the variety with leaves purple underneath, and powdered with white, streaked and mottled with yellow, all mingling in a tri-coloured shade! The effect would be less imposing, less majestic, less severely dignified, than that of the stiff quincunx formed of a single species of forest tree. Granted! At the same time, let no one contend that our combination, although not exhibiting such a patrician appearance, would be less beautiful.

Berberis vulgaris atropurpurea.—This is a variety of the common Barberry, with leaves, which, in spring, are of a vinous red colour, afterwards becoming brown by degrees, until, in autumn, they change to a purplish-green. When the plant reaches a certain age, it undergoes the common lot of mortals, loses its charms, and becomes ugly. The branches droop and become warped, and the leaves grow small and wan-coloured. Fortunately, it is easy to preserve this handsome shrub in a condition of perpetual youth, beauty, and freshness, by cutting it back, close to the ground, every second year. When cut back in this way, the plants seldom bear their yellow flowers and their red little berries; but what does that matter? Does anyone complain that the Coleuses, the Alternantheras, the Achyranthes, the Perillas, the Amarantuses (tricolor and melancholicus), do not flower? And are not the sometimes very handsome flowers of variegated-leaved Pelargoniums, and the button-like flower-buds of *Pyrethrum Golden Feather* carefully removed?

Catalpa syringæfolia aurea.—This tree, a recent acquisition, which made its appearance simultaneously among seedlings of the type, in the nurseries of M. Gaujard, at Wetteren (Belgium), and of M. Vander Bom, at Oudenbosch (Holland), is distinguished by its large leaves of a fine golden colour. They present the remarkable phenomenon of becoming green in the summer, and resuming their fine golden spring-colour again in autumn. It is an excellent subject, either for the centre of a regular group of shrubs with variegated foliage, or for the margin of a large irregular group of such subjects. *Catalpa Bungei*, *C. Kämpferi*, and the plain-leaved form of *C. syringæfolia*, are also highly ornamental green-leaved plants.

Cerasus Mahaleb fol. arg. marg.—A valuable plant, recently raised, and a great acquisition to gardens in general, but more especially for the mode of planting which forms the subject of the present notice. It is grafted as a half-standard on the Wild Cherry, or close to the ground on the ordinary Mahaleb. The last-named mode of propagation is, as yet, little practised, although it is much to be recommended. So far as we can judge from our experience up to this time, we believe we may assert that the grafts on the Mahaleb are more lasting. Plants of the variegated Mahaleb, grown in bush form, make excellent edgings to groups, on account of their moderate growth, and the facility with which they may be pruned and trimmed. Grown as half-standards, they do well for the centres of regular groups of small size, or as the principal subjects among dwarf shrubs planted as underwood, and in irregular groups. The tree grows well in dry soils, whether chalky or schistose.

Cornus mascula fol. var.—A shrub with finely-variegated leaves, and of moderate growth, in fact, rather poor unless it is planted in fertile and, especially, in moist soil. It is grafted either as a half-standard or close to the ground on the common *Cornus mascula*, and is employed much in the same way as the *Cerasus Mahaleb*, but the soil in which it is planted must be of an entirely opposite character to that which suits the *Cerasus*.

Cornus sibirica albo-marg.—This pretty shrub presents a contrast in itself, its light green white-margined leaves standing out in bold relief from the shining blood-red bark of the stem and branches.

Cornus sanguinea fol. var.—A shrub with green leaves splashed with white; bark of stem and branches brownish-red. It may be used for the same purposes as the preceding variety. Both delight in very moist positions.

Corylus Avellana atropurpurea.—This is the king of shrubs with variegated leaves! Hitherto, people were satisfied to throw away these Nut trees, by placing them at random, here and there in front of, or in, a group of other shrubs, where they look like spots of ink on a sheet of paper. When planted in zones, or in full groups with an inter-plantation of white-foliaged subjects, this shrub has a marvellous effect, and we can say that, with the white-variegated Maple, it forms the basis of the finest combinations. As yet, it is chiefly grown as a half-standard, being grafted by approach on the common Hazel, and is employed as an ordinary isolated subject, or as a central tall tree in groups of dwarf white-leaved shrubs. When grown in the bush form, it should be completely cut back to the ground every third year, after which, it sends up a fresh young

growth. This variety produces excellent Nuts when it is allowed to develop itself freely.

Eleagnus angustifolia.—All the parts of this plant—stem, branches, spines, and leaves—are covered with a greyish-white down, forming a good ground-work for relieving and contrasting all the shades of other variegated trees and shrubs. It is a valuable subject for high and dry grounds, and is sometimes even seen flourishing on certain parts of the sea-coast. In favourable positions, it attains large dimensions, and forms dense impenetrable bushes.

Eleagnus (Shepherdia) argentea.—This is a very hardy shrub in dry soils. In itself, it is nothing very remarkable, but its silvery-grey colour affords some singular contrasts to the foliage of other shrubs.

Fagus sylvatica atropurpurea.—Most people are familiar with and appreciate this fine variety of the common Beech, which it equals in hardiness. It also appears now to be almost as permanently established, as the “mast” or seed of the Purple Beech (not grafted), when sown, produces scarcely 5 per cent. of plants whose leaves are green or simply tinged with copper-colour. It is not sufficiently remembered how well this tree submits to be trimmed with the pruning-knife, or even to be clipped with the shears, and that it allows itself, without difficulty, to be confined within the narrowest limits. It may be grown as a pyramid for the centre of a group. Arbours and verandahs formed of Purple Beeches, shaped by the gardener’s shears, have a very fine effect, as also have hedges and palisades, or curtains, formed exclusively of this tree, and divided into panels or compartments by the insertion of plants of the common Beech or of the Hornbeam. We imagine that it is possible to arrive at combinations of more cheerful aspect than the stiff old Hornbeam hedges. At a country-seat at Melle, near Ghent, we once saw a covered way or tunnel formed of Purple Beeches. This is a very characteristic mode of employing it for ornamental purposes. There is a variety of the Purple Beech which has pendent or weeping branches, and very broad and dark-coloured leaves.

Hibiscus syriacus fol. var.—It is the variety with double purple flowers, and large white-margined leaves, which we mean to recommend here. This plant affords another example of leaf-variegation, which is a disease, or evidently a sign of weakness, in the individual, accompanied with doubleness in the flowers, which is a mark of plethora or surplus of vigour. This plant is cleft-grafted close to the ground, on the common *Hibiscus syriacus*. It may be objected against the *Hibiscus* that it comes late into leaf, and it is, in fact, very disagreeable to see its branches in a group of other shrubs, remaining leafless up to the end of April. On this account, we recommend that entire groups should be made of the *Hibiscus* alone, without the admixture of any other kinds of shrubs. Such groups will be very pleasing from the fine contrast of the flowers (which are amongst the latest in autumn) with the neat variegation of the foliage. They should be planted in positions fully exposed to the sun.

Hippophae rhamnoides.—This is a very hardy spiny shrub, and may be employed in any position or aspect. It is a particularly good subject for sea-side gardens or grounds. The whole plant is of a silvery-white colour.

Hydrangea japonica fol. arg. var.—We cannot too much recommend this fine plant as a subject either for the centre or the margin of groups consisting of one or more of the following handsome varieties:—*H. hortensis*, *H. J. Otaksa*, *H. paniculata grandiflora*, *H. rosalba*, &c. Such groups are particularly remarkable for beauty and vigour, when grown in moist soil, on the bank of a piece of water, with a little leaf-mould laid about the roots.

Kerria (Corchorus) japonica fol. arg. marg.—This is a handsome little shrub, of the family of the Tiliaceæ, with slender green branches, and small white-margined leaves. In early spring it is covered with a multitude of yellow flowers. On account of its dwarf stature, it should always be planted on the margin of a group.

Lonicera brachypoda reticulata.—Although this is a sarmentous shrub and more properly adapted for vases, hanging baskets, flower-stands, and rock-work, it is also an admirable subject for pegging down close to the soil as an edging to flower-beds or groups of small shrubs. Its foliage is of a delicate green, overspread with a fine-meshed golden net-work, and contrasts well with all other colours, even the commonest green.

Quercus pedunculata Concordia.—This is a superior variety of the old *Q. pedunculata aurea*, and is a most ornamental tree, its leaves and branches being of a fine golden colour. What a pity it is that the purple-leaved variety of *Quercus robur* has not a handsome habit of growth! Had it this, it would form a fine and fitting contrast to the present variety. The golden-leaved Oak is easily multiplied by cleft-grafting, at any height, on saplings of the common Oak.

Salix caprea tricolor.—This is an excellent subject for forming

* *Acer Leopoldi*, amongst others, is one of those varieties of which we should recommend the universal employment, were it more vigorous. It is especially distinguished in early spring, when the leaves first appear, by a coppery-yellow tinge of incomparable richness and effect.

contrasts, both on account of its handsome variegation, and its property of thriving in wet ground. It is advisable to cut it down close to the ground every second year, as it will then send up numerous fresh young shoots. It may be grafted at different heights on the common *Salix caprea*, or Goat-Willow.

***Salix regalis* and *S. rosmarinifolia*.**—These are two very valuable species, both on account of their easy growth and the peculiar shade of their foliage. They may be introduced into combinations for the sake of contrast, and for the purpose of forming backgrounds and vistas. Like the preceding species, it is all the better for being cut down from time to time. *S. rosmarinifolia*, when crown-grafted on *S. caprea*, or on *S. viminalis*, is a handsome tree to plant out as an isolated subject. It forms a rounded head of foliage of the most graceful aspect.

***Salix sericea*.**—A pretty miniature shrub, with slender, white, and very downy leaves. It may be grown in ball-like clumps, or, if grafted on larger-growing kinds, will form pretty little heads. There is one very ornamental variety of this plant with pendent or weeping branches.

***Sambucus nigra* fol. arg. variegatis.**—All the varieties of Elder which have variegated-leaves are most useful in plantations for filling up the spaces under the larger trees, as underwood. The golden-leaved Elder turns brown if exposed to the sun, and the mealy-leaved variety is very dwarf. These plants may always be maintained in full vigour, if they are cut back to the ground every four or five years.

***Symphoricarpus parviflorus* fol. var.**—This shrub, which is of extremely easy growth, remains naturally dwarf and preserves the shape of a small regularly-shaped ball, after being trimmed up in spring. It is valuable for small regular groups in gardens of limited extent.

***Tilia argentea*.**—A very handsome tree, of well-formed and majestic habit, great vigour of growth, and perfect hardiness. Plants of it grafted on the common Lime, have the disadvantage of growing thicker than the stock, and thus produce a very unsightly swelling or nodosity at the point of junction of the graft. As it is impossible to graft it in any other way except by approach, it may be grafted low so that ultimately it may come on its own roots. We recommend that it should be multiplied either from seed or by layering. The leaves, which are of a pale green on the upper surface and greyish-white underneath, form a pleasing contrast to any foliage of a dark-green or other colour. In some nurseries there is a variety which has leaves variegated with yellow; this has not yet been distributed to any great extent. If the variegation proves permanent, it will be a very great acquisition as a subject for isolating on lawns, or for planting in groups.

***Ulmus campestris aurea*.**—This valuable tree, for which we are indebted to M. Rosseels, of Louvain, is not only remarkable for its brilliant golden foliage, which remains unchanged under the hottest sun (unlike the golden-leaved Elder, *Ribes*, &c.), but it is also interesting on account of the characteristic form of its leaves, and its squat habit, which leads us to anticipate that it will eventually prove to be of dwarf stature.

***Ulmus campestris* fol. argenteo-variegatis.**—This is one of the oldest variegated trees that we know of. Sometimes, as the tree advances in age, the variegation diminishes; but, in other cases, age appears to make no difference. There is a gigantic specimen of this tree in the Parc St. Georges, at Courtrai. At a distance, and seen from the side on which it appears over a curtain of green foliage of other trees, the effect is that of a tree the upper part of which is covered with snow. The leaves do not turn red when exposed to the sun, like those of the variegated Weeping Elm. Although this Elm attains great dimensions, it is possible, by the use of the pruning-knife or shears, so to curtail both it and the yellow-variegated sub-variety, that both may be advantageously employed in combinations of subjects with coloured or variegated foliage. We may here, also, mention *Ulmus campestris punctata*, *U. c. purpurea tricolor*, *U. c. viminalis marginata*, and *U. montana aurea*, as very suitable for the same purpose.

***Vitis heterophylla* fol. albo-var.**—The use of this handsome little climbing Vine in suspended baskets and vases, and on trellis-work, is common enough; but few persons have any idea of the charming effect which it produces when used as an edging around large flower-beds, and groups of dark-leaved plants and shrubs. Trained on a suitably-shaped trellis, it forms an admirable centre-piece for a group or small parterre.

***Weigela rosea nana* fol. var.**—As will be seen further on, when we come to describe a few combinations, this charming little bush enters into groups of all sizes. It serves as an edging to plantations of all sorts, as well the screen-plantations of gardens (which consist of an assemblage of promiscuous subjects), as the most regular groups. Entire groups are also composed of it alone,

on the margin of which a space is left, in which, during the summer, a border of *Iresine acuminata*, *Perilla*, or the red-leaved *Amaranth* is planted. The varieties *W. amabilis* fol. var. and *W. Kosteriana* fol. var. are in every respect inferior to that which we have just described. Japan has also furnished us with the handsome *W. hortensis*, which has produced here a variety variegated with yellow, and not without merit.

Arrangement.

The foregoing enumeration comprises most, if not all, of the best subjects with variegated or coloured leaves. Other varieties, less remarkable, have been passed over in silence. Neither have we mentioned any of the novelties which have been lately announced with great *éclat*, such as the Purple-leaved Birch and the Purple-leaved Peach, which certainly are valuable acquisitions, if they correspond to the eulogistic descriptions which have been given of them. We now come to the question of how to dispose our plants in an artistic, tasteful, and judicious manner, fine effects being produced not only by these trees themselves, but also when they are used in combination with other trees and shrubs which have green leaves. The shape or outline of the group is altogether an arbitrary matter. Here the little details of design and subdivision, which please so much in beds of herbaceous plants, are worse than useless. The extent of the group is also a matter depending on circumstances, but any pleasure-ground, of the most modest size, whether it be round, elliptical, or, in fact, any shape whatever, may be embellished with pretty and suitable combinations. For small groups, it is well not to vary the species or varieties too much, and not to allow them to attain a high stature. This last advice does not, as some might think, render the forming and keeping of small groups more difficult. All that is required is a judicious use of the shears, which will also serve to increase the beauty of the groups. For all small groups, whether regular or irregular in outline, we recommend one or other of the following combinations, the first-named subject in each being for the centre, and so passing through the rest to the margin.

A.	C.
<i>Corylus Avellana</i> purpurea.	<i>Weigela rosea nana</i> eleg. var.
<i>Acer Negundo</i> fol. alb. var.	<i>Leycesteria formosa</i> (leaves, dark green).
<i>Berberis vulgaris</i> atropurpurea.	<i>Kerria japonica</i> fol. var.
<i>Lonicera brachypoda</i> reticulata.	<i>Vitis heterophylla</i> fol. arg. var.
B.	D.
<i>Hippophaë rhamnoides</i> .	<i>Acer Negundo</i> fol. arg. var.
<i>Berberis vulgaris</i> atropurpurea.	<i>Corylus Avellana</i> atropurpurea.
<i>Eleagnus argentea</i> .	<i>Symphoricarpus parvifl.</i> fol. var.
<i>Symphoricarpus parvifl.</i> fol. var.	<i>Spiræa callosa</i> alba nana.

These four examples may be varied *ad infinitum*, either by transposing the plants named in them, or by substituting others. Small groups are very much improved in appearance, if margined by a border of perennial herbaceous plants. For instance, *Campanula carpatica*, which has blue flowers, forms a pleasing contrast to any light-coloured foliage, and *Spiræa* (*Hoteia*) *japonica* is equally effective when opposed to purple or dark green. We employ these two plants very largely for this purpose. We also, sometimes, use an edging of variegated Ivy or *Euonymus radicans*, whose leaves are marbled with white and tinged with rose, for these little groups. In groups of large size, our resources are more extensive. In them we can have a large tree in the centre surrounded by other trees trained as pyramids or half-standards, passing on in succession to zones of shrubs with variegated or coloured leaves.

We have already spoken, in the course of this article, of plantations of shrubs with white, grey, or purple leaves, in a single or double line (each formed of one kind of shrub) before groups of miscellaneous subjects. We again call attention to this subject in remarking that dark-coloured foliage is best suited for margining groups which fall directly under the eye, white foliage for the most distant parts, while grey-leaved plants, such as *Eleagnus*, *Hippophaë*, *Shepherdia*, *Salix rosmarinifolia* and *regalis*, *Hydrangea glauca*, &c., are best adapted for the background. In plantations of this sort, advantage may also be taken of the colour of the bark of the various subjects. For instance, a tasteful combination of *Cornus sanguinea* and *C. sibirica* (which have red bark), *Kerria* and *Leycesteria* (fine green bark), *Salix daphnoides* (nearly glaucous bark), *Salix vitellina* (yellow bark), and *S. purpurea* (purple bark), produces one of the finest effects imaginable.

What we have just said will suffice to give an idea of the immense resources which trees and shrubs afford us for producing charming effects in our gardens. In pointing out the course to follow in making these artistic combinations, we by no means require that all the plantations in a garden should be made in this manner, and we should be the first to condemn any such abuse, knowing well that a distinction must be drawn between landscape-gardening properly so-called, and such artificial embellishments as we have

described. These will only contribute favourably to the general effect when not too lavishly indulged in.

The preceding notes on trees and shrubs with variegated foliage, and the most effective ways of grouping them, contributed by M. Fr. Burvenich to the *Bulletin d'Arboriculture*, contain much useful and interesting information. W. M.

CUPRESSUS CORNUTA.

THIS Californian Cypress is described by some authors as a variety of *C. californica gracilis*, while others make it a distinct species. It forms a small bushy tree, from 16 to 20 feet high, with numerous spreading branches, and small scale-like leaves, closely set together, broad at the base, and pointed at the apex. It is particularly distinguished by the shape of its cones, of which we give an illustration. These are of a dark brownish colour, streaked with lighter lines, each of the four scales bearing, near its apex, a horn-like projection, nearly half-an-inch long, whence it derives the specific name *cornuta*. These horns are generally curved at the point, as shown in our engraving, which represents the cones in their natural size. The tree is a native of the mountains of California, and is a hardy and tolerably ornamental subject.

Half-Hardy Shrubs.—The following shrubs have stood out all the winter on the Orchid-house walls at Kew, viz.:—*Fabiana imbricata*, a plant closely resembling an *Erica* in habit and flower, and, though a native of South America, generally hardy. It is a first-rate free-blooming window plant grown in a pot, and bears tubular flowers, of snowy whiteness, about an inch long. It is now blooming outside as above. *Coronilla glauca*, another old-fashioned greenhouse or window shrub, having pinnate glaucous leaves and clusters of golden-yellow Pea-like flowers, also appears to do well planted out. In the Isle of Wight, Devonshire, and the Channel Islands, most of our cool greenhouse plants grow planted outside far more vigorously than when grown in pots. *Aloysia citriodora*, or Lemon-scented Verbena of our cottage windows, is now growing freely, and, if possible, its perfume is intensified by outdoor culture. The last plant to which we shall allude, is *Phygelius capensis*, a scarlet-flowered shrub well adapted for open air culture as a wall plant in warm sheltered localities. Last summer this plant was 5 or 6 feet high, and bore a fine display of its drooping scarlet flowers in terminal panicles. It makes a good plant for the herbaceous border when in a small state, and used to grow and flower very freely at Chiswick when only about a foot in height. Anyone possessing old greenhouse or half-hardy plants that are no longer suitable for pot-culture, cannot do better than give them a trial outside on any bare bit of wall not already covered. They should be planted out as soon as possible after all danger from spring frosts is over, and induced to grow freely and establish themselves as early as possible by careful watering, so that they may be better able to resist the sudden fluctuations of our uncertain climate.—B.

A Giant of the Forest.—A noble Pine tree has recently been felled in the forest near Erlisbach, the property of the Canton of Aargau, Switzerland. Its diameter, according to a continental paper, was 5½ feet at the base, and its cubic contents 800 feet. It sold for 500 francs (£20.)

Judas Tree (*Cercis Siliquastrum*).—This may be found in many gardens round London, where its branches are just now laden with clusters of rosy-purple flowers. There is a good specimen of it near the entrance to the herbarium at Kew. It is ornamental when in leaf, and deserves planting, if only as a spring-flowering tree.—B.

GARDEN DESTROYERS.

THE LACKEY MOTH.

(BOMBYX NEUSTRIA).

WALKING in the garden the other day, I came upon a veritable garden destroyer, and one which plays terrible havoc amongst fruit trees. The upper branches of an espalier Apple tree were already denuded of their leaves, and, though the remaining portion of the tree was as yet unharmed, it would not have remained so long, had the caterpillars not been discovered and captured, for they would soon have devoured every leaf. They were the larvæ of one of our commonest and most destructive of moths, the lackey (*Bombyx neustria*). In a fork of the tree was their closely woven web, not easily seen by an unpractised eye, as its light and airy texture took the form of the branches upon which it was constructed. However, it was seen, and 121 caterpillars were soon taken. For the benefit of those who may not know this larva by sight, I will describe its appearance. It is decidedly remarkable for its beauty, being many-coloured, and the various tints and shades and markings are so exquisitely arranged that they are nearly certain to excite the wonder and surprise of the beholder. The dorsal line is brilliant white, with a narrow black velvety stripe on either side of it. Next to this is an orange stripe, then a broad black one, spotted with blue; then a narrow orange stripe, then a narrow black one; next to this there is a light blue stripe, speckled with very small black dots, and, below it, two scalloped lines, one black and the other orange; next to this is a blue line, speckled with black, and a few orange markings beneath. The head is blue, and has two black patches, like eyes, on the forehead. The eggs are laid on the branches of the tree in a ring round the bark, and the moth flies in July and August.

OWEN WILSON.

Cones of *Cupressus cornuta*.

Now is the Time to Attack Wire-worms.—Wherever the temperature of the soil has risen to 54° Fahr., there will wire-worms be found in a pupa state, and that is the time to wage war against them. They lay about 1½ or 2 inches below the surface. Flat-hoe between all crops, whether there are weeds or not. The hoeing will, in many instances, disturb the helpless pupæ, and bring them to the surface, where birds will find those that have not been crushed. I have also found that treading the ground between the rows crushes many. In fields, roll

wherever the roller can go without injury to the crops, especially in the case of old pastures. This will destroy more wire-worms than at any other season of the year. They remain in the pupa state about thirty days, so that every one destroyed now prevents the breeding of hundreds. The beetle only remains in sight a few hours. —W. PRESTOE.

Destruction of Crickets.—Some two years ago my Vineries were over-run with these, and being large houses they could be counted by thousands, I may say, indeed, tens of thousands, and they eat the young foliage of the Vines to such an extent that it became a serious matter how to prevent the mischief. I consulted Mr. Chase as to whether his blackbeetle destroyer would kill crickets; he said he thought not. However, I placed the contents of six boxes about the haunts and runs of the crickets, and at the foot of each Vine; they disappeared like magic.—J. PERRETT, *Herne Hill, Dulwich*.

THE FRUIT GARDEN.

PEACHES AND APRICOTS ON OPEN WALLS.

THESE have set well and have begun to swell; the young wood will, therefore, soon require thinning, an operation which must be performed with care, as, when a wood bud is roughly pulled off, the bark of the shoot adheres to it, inflicting a wound from which sap soon exudes. Where three fruits have set in one cluster, or in such close proximity that one would injure the others if allowed to remain, two must be removed, taking care to leave the largest and best formed of the three. Disbudding the shoots should not be done all at once; on the contrary, they should be removed at three or four different times; first, when the flowers have fallen off, and, subsequently, at intervals of two or three weeks. The shoots intended for the following year should not, I consider, be stopped at all, but should be allowed to grow at will, with the exception of any gross strong-growing shoot, which should be wholly removed, serving all deformed and badly placed shoots in the same manner. In this way, those that remain get more air and light, than they otherwise would get. Tying in those intended for future working is more a disadvantage than otherwise, and should not be practised except where they appear to be unsightly. A good washing with the garden engine, at least twice a week, will be found beneficial; even twice a day is not too often, if time can be spared for the purpose. I have, however, seen excellent Peaches and Apricots gathered which have never been operated on either by engine or syringe. The weather has been favourable to aphides, and, if undisturbed, they will soon overrun everything. Various antidotes for their extermination have been recommended, but I have found nothing more efficient than a good syringing with tobacco-water. This should be given in the evening, and, if too strong, any ill effects can be counteracted by a thorough syringing with clean water in the morning. This season I have seen Pooley's tobacco powder used with good effect, and, if put on with a distributor, a very small quantity suffices to destroy all such insect pests on a large tree. Before this is used, the trees should receive a good syringing, say about three o'clock in the afternoon, and, before they have become dry, apply the powder, which may remain on all night, and be syringed off in the morning. I have also seen soap suds used to destroy aphides, but they leave an unsightly sediment, and it is doubtful if they kill the aphides. Watering at the root in dry weather, when the trees are in a good growing state, is of great benefit to them, both as regards health and the production of good fruit, but, unless given often, and in large quantities, it is of little value. Where the soil is light, of course, more water is required than where it is a heavy clay. As a general rule, water well both at top and root, thin liberally, keep insects in check, and good crops, in all favourable seasons, may be confidently expected.

JAMES MORRISON.

Wotton Gardens, Aylesbury.

WATERING PINES.

I HAVE read Mr. Muir's remarks on this subject (see p. 402), wherein he incidentally refers to my practice in watering Pines as not being in accordance with his and that of other Pine growers, which may be the case; but that abundant watering up till the ripening of the fruit is attended with the disastrous results which he describes is, according to my constant experience, not by any means the case. I quite agree with Mr. Muir that "excessive watering" is decidedly wrong, but I am not aware that anyone has ever recommended such irrational practice. I leave $2\frac{1}{2}$ inches of space in my fruiting-pots to ensure copious watering when watering is done, and I water just as copiously when the fruit is ripe as at any other time. My object in doing this is to ensure well-finished fruit and healthy suckers, and I have always succeeded in securing both. The following facts will probably be a sufficient reply for Mr. Muir. The fruit which I have sent to table has always been pronounced to be excellent. No black cores have been found, but they have been so exceedingly rich as to fill the plate with juice whenever they were cut up. So much for home experience, but I have other facts. At the

Royal Society's Show at Nottingham, a few years ago, I exhibited six or eight Pines, all of which had been watered well till the day before the show. They were Queen's, which ran from 4 to 5 lbs. apiece, and all received first or second prizes, the only important opposition being from Mr. Miles, of Wycombe Abbey, who told me that he had never seen better-finished fruit than mine, and Mr. Muir will find them described in the horticultural papers of that date to the same effect, *i.e.*, as being "very perfectly ripened." A noted fruit dealer, from Glasgow, offered at the time to give me the highest price for them and take his chance with them at the end of the six days' show, but I declined. In 1871 I entered three Pines in the class for "two or more kinds" at the Manchester "Rose and Fruit Show," and they were awarded the first prize solely on account of their finely-swelled and finished appearance, though much larger fruit was opposed to them. In two collections of fruit, which I exhibited at the same show, the Pines were largely instrumental in securing me the first prize in both cases. At the Royal Society's show at Manchester, also, I exhibited six Pines which received a prize; and one fruit, in a collection of mine which received a first prize, was reported on by the press as being one of the finest Queen Pines in the show. At York and Leeds I have won first prizes on several occasions for Pines, and also at other places. Further, I can always get the highest prices for our Pines, and a fruiterer, with whom I deal, informed me that his customers said the Pines from this place were the best they had ever eaten. So much for facts. Now all these Pines, above noted, exhibited that peculiarly plump and glistening appearance which indicates, not only a well-swelled fruit, but one sound to the core, and the plants from which they were cut were treated exactly as I have described at page 217 of THE GARDEN. I would ask Mr. Muir if he knows under what conditions the Pine grows and fruits in its own native habitat? I am informed that it makes its growth during the rainy season, and fruits at the same time, or immediately afterwards; but in the steaming climate, of which it is a native, the soil is at no time dry, let alone parched, like the soil in a pot above hot-water pipes. Moreover, the finest fruits which have been produced have, as a rule, been grown on the planting out system, and it is a well-known fact that a bed of soil does not soon get dry. I have grown the Pine both ways, and I know that the bed will retain its moisture for months, though no water is given during the time; and, no doubt, this equable condition of the soil, as regards moisture, has much to do with the excellence of the fruit produced under such conditions. I am sorry to hear from Mr. Muir that in "very many instances" certain dates are put down and strictly adhered to in watering, irrespective of weather and other matters, *i.e.*, whether the plants want water or not. Let us hope that such practices are confined to those out-of-the-way regions which THE GARDEN, and similar instructors, have not yet reached, but towards which they may be travelling like the light from the sun to those far away planets that have been waiting so long for rays which have not yet reached them.

J. SIMPSON.

Wortley.

WIRING GARDEN-WALLS.

I HAVE deferred answering Mr. Grieve's courteous critique upon my views on this subject, to see what response would be made to his request for the opinions of those who have fully proved the system; for mere conjecture on this, as upon hundreds of other matters that at first sight seem to be all that could be desired, are often, in practice, found wanting. When I first had a wall wired, I was delighted with its appearance. The wire, one-eighth of an inch thick (if stronger, and fixed close to the wall, tightened up, as necessarily it must be, there is difficulty in getting the tying material behind it; if thinner, and strained, even until it breaks, the branches that require any pressure to bring them to the wall will spring it away further than the distance I mentioned), seemed to say, "No more nails and shreds!" But I soon found that, unless the bast was crossed once or twice betwixt the wire and the shoots, so as to keep the wood from contact with the wire, I had any amount of gumming; then, again, unless the young wood was allowed, at the time of tying, double its thickness for after expansion, the shoots were half cut off and injured before

the end of the season. As the trees grow up and get stronger, unless the wire is so thick as in itself to remove the shoots too far from the protecting influence of the bricks, they will spring it away, in many places, quite as far as the distance I name. Again, to make the system complete, the wire should run on every joint, instead of, as is usually done, every third course of the bricks, which would make an expensive job still more costly. In the three-course intervals the shoots, in innumerable places, will bulge up between the wires an inch or more away from the bricks. From this, Mr. Grieve will see that the distance the shoots lay from actual contact with the wall (their great protection) when tied to wires, as compared with being nailed is not so little as he supposes, and I need not remind anyone possessing Mr. Greive's experience and observation, that it is in small—infinitesimal, if you like—differences, that success or failure depend in matters horticultural. To name wired walls along with wired fruit trellises, as improvements in gardening, is simply to couple a mistake along with a system of fruit culture that is admirable, the only drawback being first cost. In reference to nails not entering the bricks I never yet met with any bricks that ordinary cast-iron nails would not enter without one in fifty breaking. The injury they do to the bricks, if the work is done with care, is a great deal more imaginary than real, not so in respect to nailing into the mortar. In reply to "Fair Play," who asserts that I have not given a single valid argument against wired walls, may I remind him that what I have advanced are amply sufficient and valid, and that mere assertion to the contrary, neither proves nor disproves anything. I can assure him that I have tried the system fairly, and without prejudice. Why speak of it as a new French system, when it has been in the country, to my knowledge, over twenty years. If it deserved such unqualified praise, fruit-growers in this country must be awfully dull in not more generally adopting it.

T. BAINES.

Peach and Nectarine Trees Dropping their Buds.—In the spring of last year I planted a new house with Peaches and Nectarines, and some of the branches of the trees did not break well. This year they bloomed pretty well and bear a fair quantity of fruit for the first year; but, on many of the fruit-bearing branches the buds have all dropped, leaving the fruit naked, which, I suppose, will not come to perfection; the trees will, also, have a deformed appearance by the failure in growth of the branches. I do not think the valuable observations which you have lately published on watering Peaches will help me in this case, as I believe the trees in question have had sufficient water.—KENT. [The dropping of the buds on the fruit-bearing branches of the Peach and Nectarine trees in "Kent's" newly-planted Peach house may, perhaps, be owing to insects. Early this year I had some manure brought from a farm-yard to top-dress the inside of a Peach-house border, and this brought into the house a beetle, or "bracken clock," as it is called here. As soon as the Peaches and some young Vines began to get into leaf these beetles began to eat the young shoots, and destroyed many of them before they were found out. These beetles feed at night and are easily detected by searching for them with a candle; they drop down as if dead when touched. If they have been the cause of eating your correspondent's Peach and Nectarine tree buds, it will be seen by the nibbled state of the foliage. If there is reason to fear that the soil of the border is the cause, and not insects, I should re-plant the trees in the autumn in fresh soil, and see that the drainage is perfect.—WILLIAM TILLERY.]

Our Fruit Crops.—We never had such a promise of a bountiful fruit year as we have this season. Peaches have set by the score, and Plums by the thousand. The earliest varieties of Pears set well, while the late ones are one sheet of beautiful snow-white blossoms. Apples also promise, so far as bloom goes, to be the best we have had for years past; while Cherries (our most precarious fruit here) have all set well. Currants and Gooseberries, the latter of which are ready for tarts, are quite ten days in advance of former years, and are both literally laden with fruit.—R. GILBERT, *Stamford*.

Tobacco-Water.—At what strength should tobacco solution be used when syringing Peach trees?—H. S. [We have found that steeping about half-a-pound of shag tobacco in a large watering can is sufficient. The tobacco must be tied in a calico or canvas bag, to prevent the pieces from choking up the syringe when using the solution. After the first day's solution is used the water will not be so strong, and a little more tobacco may be added to the bag to keep up the strength for four or five steepings of the same tobacco. If the strong tobacco liquor from the tobaccoists is used, about a quart of it to a large pailful of water will destroy all the aphids on Peach trees with two or three applications.—W. TILLERY.]

THE KITCHEN GARDEN.

THE SEASON AND KITCHEN GARDEN CROPS.

THE late winter has been throughout one of the most favourable to the horticulturist on record for performing both outdoor and indoor operations; and the spring months, so far, have been quite as favourable as their predecessors. There have been ample opportunities for pruning and nailing, for preparing and pulverising every kind of soil, and for securing seed-beds. Thus a good foundation has been laid for luxuriant and healthy crops of all kinds of vegetables, provided succeeding operations are duly attended to. The season is also, judging from the progress of vegetation, a tolerably early one; a circumstance which, however, gives none the better prospect of a general crop of early vegetables or heavy crops of fruit, judging from previous experience. Notwithstanding the atmosphere has been dry, north-east and easterly winds and many frosty mornings and nights, have cut down the early foliage of Potatoes in places shaded from the evening and subject to the first rays of the morning sun; also in some low-lying, damp, imperfectly-drained spots, the Potatoes are also cut rather badly; but, on dry sheltered borders, exposed and well-pulverised quarters, fields, and dry spots, open to the full sun and wind, the Potatoes are strong, sturdy, and free from frost-bite. In this locality the Lilac, in variety, was in full bloom by the 10th of April. The White Thorn was likewise to be seen in full bloom, in warm sheltered spots. Also the Laburnum, Horse Chestnut, and other spring-flowering trees, shrubs, and flowers, were in about the same condition by the middle of April. I called on Mr. John Westcott, market gardener, at Topsom, the last week in April, and found his crop of Strawberries, as usual, something wonderful. No matter what structure they were placed in, whether in low or high pits, Vineries or Peach-house, on shelves near or far from the glass, on the brick kerbs of pits, or on tan or dung-beds in the pits, or whether they were placed in a north, east, west, or south aspect—all were alike remarkable for a wonderfully heavy set for swelling, ripening, and the finishing of a perfect crop, bearing, in some cases, from 100 to 150 swelling fruits on one little plant growing in a small pot? The fruit ground, too, I was pleased to see in a fine healthy prosperous condition. Small fruit abundant, a large quantity of fine Gooseberries being gathered for the London market on April 20th. Cherries, Plums, and Pears, in general, well set; indeed, as to Plums, on some varieties, every blossom was set, and the size of Hazel Nuts, all in clusters. Apples showed strongly for a heavy blossom, and were beginning to open some of the bloom. A good strong open foliage was fast unfolding, which will be the means of much shelter. This, I observe, is pretty general in the orchards in various localities, and is owing, no doubt, to the few warm days which occurred in April. In all the gardens I have seen, there seems to be a good crop set of Apricots, Peaches, and Nectarines, and, in reply to several inquiries I have had the opportunity of making, I am informed that these fruits, in general, are pretty well set; indeed, at present, there is a good prospect of fair crops.

JAMES BARNES.

Exmouth, Devon, May 6th.

EARLY CABBAGE.

CABBAGES, in a suitable condition for the table, are more esteemed in April and May than later in the season; therefore, any system or mode of culture that tends to hasten their maturity is worthy of consideration. From the 18th to the 25th of July has hitherto been generally considered the right time to sow the seed of the earliest crop for spring use, making, of course, some allowance for the degree of latitude in its relation to climate, a point to which I will refer more fully presently. During the last few years I have tested various varieties of Cabbage, with the object of ascertaining the variety most suitable for early sowing. I need scarcely say that early sowing has much to do with early maturity; but most varieties, if sown too early, will, most assuredly, "bolt;" that is, they will run up into flower instead of forming hearts, especially if the winter is mild. For early sowing to stand the

winter, the Enfield Market, according to my experience, is the most trustworthy. It rarely bolts prematurely, turns in quickly, is of fair size; and is in all respects a first-rate Cabbage. Now, as regards sowing for early crops, I have no sympathy with the cultivator who fixes a certain day for the annual performance of a particular operation, and then sticks to it through thick and thin, without any regard to local conditions. On the other hand, however, much may be said in favour of punctuality, especially in sowing or planting crops that are required at a particular time. We usually make the first sowing of the Enfield Market from the 8th to the 12th of July, and by sowing a week or ten days earlier than is customary we gain frequently three or four weeks in spring, but then every variety will not stand it. The second sowing, which may include other varieties, should be made from the 18th to the 22nd; and a third sowing about the end of the month, to stand in the seed-bed till spring, as, if the weather is unusually severe, they are less affected by it, and may be easily sheltered. Although I have thus specified three periods for sowing, it does not follow that any large quantity of seed need be sown; every one will easily understand that this is a matter that must be entirely governed by the demand. In sowing the seeds, if the weather is dry in July, let the bed be thoroughly soaked with water previous to sowing. Cover with fine soil, and shade with netting, or something similar, till the plants appear. A sufficient number of the first sown should be pricked out as soon as they are large enough. Transplanting has a tendency to prevent over-luxuriance, and its influence will be felt, as the season advances, in preventing undue growth or premature bolting. Plants, so treated, will be ready to plant out finally about the third week in September, and may appropriately follow the Onion crop. If the land is in good heart, there is no necessity for digging or manuring. Simply hoe the surface over, draw rather deep drills 18 inches apart, and put the plants out in the drills, from 15 to 18 inches apart, with a dibble, planting firmly. The late crops may have more room allotted them. If the plants are strong, which in all probability they will be when put out, there is no occasion to water them, even if the weather is dry. A slight check from this cause at that season will do them no harm. An old market-garden friend, who was a successful early Cabbage grower, frequently left his plants exposed on the surface of the ground several hours before planting them, his theory being that a check at that time was beneficial in preventing premature bolting. The plants from the second sowing may be put out in October; and the third sowing, as I have previously stated, may remain in the seed-bed till spring, as a precautionary measure. Wheeler's Cocoa-nut Cabbage is a capital one for sowing in spring for late summer use. It is not large, but very mild in flavour. One word more as to latitude, and its influence upon climates, in reference to seed-sowing. The dates I have given are such as I have found applicable to the midland districts. In the south, sow a few days later; and, in the north, five or six days earlier.

E. HOBDAV.

* NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Best Four Broccoli.—Four kinds of Broccoli which everybody should grow are Walcheren, for autumn; Snow's White, for winter; Watts's Excelsior, for mid-season; and last, but not least, Cattel's Eclipse. Excelsior here, this season, is simply perfection.—STAMFORD.

Kitchen Garden Crops.—Here Peas are in full flower, William the First being the earliest to bloom. Cabbages have been cut for a month past. Hardy Hammersmith Lettuce is plentiful, and Potatoes are looking well.—R. GILBERT, Stamford, May 6.

A Good Edging for a Kitchen Garden.—Sow in a small bed best Moss-curved Parsley in August, and, about April 10th, prick it out along the edges of the walk 1 foot apart, and two rows instead of one. Behind it sow a drill, or better, sow in boxes Dell's Beet, and plant it out as soon as it is ready. These two common but all-important plants give the vegetable quarters a nice downy appearance.—BURGHLEY.

Road Scrapings as Manure.—Will you kindly inform me as to the properties of road scrapings, i.e., how they will act in the way of manure on garden ground?—A CONSTANT READER. [The manurial properties of road scrapings are various, according to the character of the materials used in making and mending the roads. On strong soils road scrapings are beneficial in disintegrating them, and rendering them more fertile for the growth of vegetables or fruit trees. If the scrapings are collected from roads on which calcareous materials are used, they are best suited to soils deficient in lime. There are some manurial properties in scrapings taken from roads on which much horse traffic occurs, owing to the quantity of droppings in it.—W. T.]

WORK FOR THE WEEK.

Flower Garden.

SHRUBBERIES are now gay with early Rhododendrons, Ghent Azaleas, Berberises of different kinds, scarlet and common May; masses of blue Iris, and other herbaceous plants, also set them off to advantage. Spring flower gardens are yet brilliant with Heartsease, Trolliuses, Daisies, Alyssums, Iberises, Wallflowers, Saxifrages, Tulips, and various other plants. Preparation should now be made for bedding plants. Although many persons are reluctant to remove the fading beauty of spring for the more gaudy display of summer, unless this is now done, summer droughts may overtake late-planted beds before their occupants get established. Indeed, in sheltered warm situations, Pelargoniums have already been planted out. Flower-beds should now be edged with Gazania, variegated Arabis, Japan Honeysuckle, and dwarf variegated Grasses; Violas should be divided and planted, and likewise such plants as were divided and transplanted into nursery lines in February and March. Polyanthuses should be divided and planted in lines, the soil for their reception having previously been enriched with fresh loam. Early spring flowering Violets should be lifted, the offsets separated from the parents, and transplanted in lines 12 inches apart, a handful of sandy soil being placed around each root. Sweet Peas, Tropæolums, and other annuals raised from seed in beds, wall-borders, or in boxes in frames, should now be planted out permanently.

Greenhouses and Stoves.

Conservatories are now gay with Azaleas, which are coming into flower without the aid of fire-heat. In order to prolong their beauty, they should be carefully shaded from bright sunshine. New Zealand plants, such as Boronias, Eriostemons, Pimeleas, Tremandras, Everlastings, &c., now coming into flower, should be neatly staked. These, as well as Heaths, occupy the coolest and most airy part of the conservatory. All plants in active growth should receive plenty of water; and those done flowering should be freely syringed, and have the benefit of a little artificial heat and shade. Azaleas, Rhododendrons, &c., done flowering, should be re-potted, pressing the soil rather firmly in the pots. Soft-wooded plants, such as Celosias and Balsams, should not be allowed to receive any check from under-potting, but should have plenty of root room whilst growing; a little bottom-heat and air being given them at the same time, also a little manure-water. When it is desired to retard the flowering of Balsams, the flower-buds should be picked off as they appear, until say a short time before they are required for use. A few Balsam seeds should also be sown in pans in gentle heat; as soon as the young plants appear, they should be placed near the glass, and when fit to handle should be potted off singly. Humeas required for conservatory decoration should have now received their last shift, using for the purpose a compost of loam and well-decomposed manure. Stove plants, which are now making good progress, should have plenty of light, heat, and moisture; but shaded from strong sunshine. Stephanotis, Allamandas, and Dipladenias should have their shoots regularly trained as desired. Orchids making growth should have plenty of water, and such as are in flower should be removed into a drier house than that in which they have been growing. Ferns should be kept well shaded; paths, stages, and walls being kept moist by means of frequent sprinklings with water.

Warm Orchids.

Keep a careful look out for insect pests, when hot weather sets in, and do all that is possible to prevent their appearance by frequent syringings, and occasionally sponging every plant with clean tepid water. Gradually increase the temperature, and take advantage of every opportunity to give an abundant supply of fresh air without causing cold draughts; the bottom ventilators may be left open night and day, taking the precaution to cover the openings with tiffany, or, what is still more durable and better, perforated sheets of zinc or fine wire gauze netting. Care must now be taken not to let the internal temperature be influenced by the rapid and sudden fluctuations which are now taking place outside more than can possibly be avoided, for the young growth is easily checked, and when this happens the plant is often ruined for a season at least. Keep up humidity by sprinkling the floors and benches; and, if the houses are inclined to become very dry, a layer of Sphagnum Moss may be laid over the staging, and kept wet by constant sprinklings. Any bare spaces under the central stage or side benches may be covered with a layer of soil, and then planted with Selaginella Kraussiana, Tradescantia zebrina, and other creeping plants. This not only adds to the attractions of the houses, but assists materially in maintaining that uniform and genial state of moisture in which Orchids, above all other plants, luxuriate. If other plants are admitted into the Orchid houses, carefully exclude all weakly or unhealthy specimens that are liable to be infested with thrips, red spider, or other insect pests.

The best of all plants for associating with Orchids in bloom are Palms, Dracenas, and other hard-leaved foliage plants. The following are now in flower, viz., *Dendrobium nobile*, *D. Infundibulum*, *D. Jamesianum*, *D. transparens*, *D. densiflorum*, *D. fimbriatum*, *D. Wardianum*, *D. devonianum*, *D. bicolor*, and *D. albo-sanguineum*, *Vanda suavis*, *V. tricolor*, *V. Cathcartii*, *V. cærulescens*, *Cypripedium nævium*, *C. villosum*, *C. hirsutissimum*, *C. concolor*, *C. Roezlii*, *C. caudatum*, *C. Stonei*, *C. lævigatum*, and *C. barbatum*. The wax-like *Lycaste Skinneri*, *Anguloa Clowesii*, *Cattleya Mossiæ*, and *Lælia purpurata* are now at their best.

Pits and Frames.

Polyanthuses, Pansies, and Auriculas should now be raised from seed in cold frames, in boxes or pans. Cinerarias and Primulas should also be raised from seed sown in gentle heat. Auriculas done blooming and kept in frames should have the sashes removed; some may also be placed out on sheltered situations. The seed vessels of all, if seeds are not wanted, should be removed. Seedling Cyclamens should be kept near the glass in a moderately warm temperature; old plants producing seed should be placed on shelves close to the glass in cool houses; some of the others should be placed in cool, shady frames, or on a bed covered with ashes behind a north wall. Stocks should be re-potted; the best of the single ones being kept for seed.

Indoor Fruit Department.

Pines in active growth should now be abundantly supplied with light, heat, and moisture, but, as soon as they begin to ripen, watering should be to some extent discontinued. Successions should receive a little weak manure-water, and the walls and the tan beds should be syringed with the same. In the case of Vines, the fruit on which has done colouring, the temperature should be reduced a little and the atmosphere kept rather dry. Pinching, thinning, &c., should be attended to in the case of later crops. Peaches and Nectarines passed the stoning period should have the temperature increased to 65° at night, and from 80° to 85° during the daytime. The borders should be well watered before the fruit begins to ripen; for, if done afterwards, the flavour is often deficient. Figs growing should receive plenty of water at the roots and overhead; those ripening should have the supply diminished a little; but not too much, as that would destroy the second crop. Cherry trees ripening off their crops should be kept rather drier than usual, and when the fruit is gathered they should be gradually hardened off, and after a time completely exposed.

Hardy Flowers.

A mild and genial April has been succeeded by extremely cold weather—so cold, in fact, as to more resemble winter than May—and hardy flowers, many of which looked so promising last month, have received a severe check, and, in many cases, the bloom has been completely destroyed. Several large tufts of *Dielytra* (*Dicentra*) *spectabilis*, which a fortnight ago looked flourishing, have been completely denuded of both flowers and foliage by the recent severe frosts and cutting winds. To have this plant in fine condition, indeed, it is desirable to plant it in a warm sheltered spot, such as at the foot of a wall. The flowers of that favourite old plant *Gentiana acaulis* have also suffered much, and so have those of many varieties of *Iris*. Notwithstanding the inclemency of the weather, however, there are a good number of attractive hardy plants at present in flower, conspicuous among them being the *Trolliuses*, *Ranunculuses*, *Alyssums*, and the pretty *Lithospermum prostratum*, which is now in its best condition. In the case of this latter plant a charming combination may be made by the use of it and a variegated form of *Helianthemum* planted alternately with each other as an edging, the effect of which is excellent, the variegation of the one appearing to show forth the lovely blue of the other to the fullest extent. Various kinds of *Squills* are now finely in flower; and a form of *Scilla nutans*, called *Violacea*, appears to be an improvement on the many varieties of this species now in cultivation. Its flowers are of a deeper blue than those of any other form with which we are acquainted. *Pæonies*, too, are just coming into bloom, but the fine double variety of *P. tenuifolia* has suffered much from the severity of the weather. The poet's *Narcissus* is still finely in flower, and so is the lovely *N. triandrus*, which has withstood the weather better, perhaps, than any other species. Absence of rain and cutting winds have, in many cases, prevented the planting out of annuals and biennials raised in pots; also the division of scarce perennials. Hardy perennials requiring stakes should be attended to, and the stock of spring-flowering plants, such as *Aubrietias*, *Alyssums*, &c., should, if necessary, be increased by means of cuttings, which root readily at this season. Sowings of annuals for successional blooming should also be made, and those already up should be thinned if necessary. Any rare plant which may be seeding should have the seeds gathered as soon as ready.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

MAY 13TH.

THE chief attraction at this exhibition was the pot Roses, especially those shown by Mr. George Paul and Mr. Charles Turner, whose collections were so equal in point of merit that many present considered that equal prizes here, as at the Palace, should have been awarded them. They were, however, placed first and second in the order in which the names stand. Celine Forestier, a sulphur-coloured Noisette in Mr. Paul's group, was a rare example of good culture, and was very skilfully contrasted with Madame Victor Verdier, a vivid crimson-rose of good form and substance on the one hand, and Charles Lawson, a bright rose variety, on the other. This arrangement set off the group to excellent advantage. Its weak point was a plant of *Souvenir d'un Ami*, a lovely flesh-tinted Tea Rose of rare excellence, but hardly at its best on this occasion. Other varieties were Juno, rose edged with white; Camille Bernardin, a deep crimson-purple; Madame Villermoz, a beautiful pale Tea-scented variety; John Hopper, a well-known old favourite; President, flesh; Vicomte Vigier, rich crimson-purple; and Elie Morel, of a bright silvery rosy-hue, and very effective. In Mr. Turner's group the finest specimen was, undoubtedly, La France, one of the very best of light Roses, and, in this case, it was a profusion of splendid blooms of good substance, their freshness and beauty being further enhanced by juxtaposition with the brightest and greenest of foliage. The same group included fine plants of General Jacqueminot, Juno, Charles Lawson, Paul Perras, a rich rosy-lilac, beautifully flowered; Paul Verdier, a crimson-purple; Victor Verdier, rather lighter in colour than the last, but a fine Rose; *Souvenir d'un Ami*; Beauty of Waltham, similar to, but better in the present instance, than Paul Verdier; Madame Levet, a fine full incurved flower, and one of the best specimens in the group, together with *Souvenir de la Malmaison* and Anna Alexieff, both fine old-established varieties, either as specimens or cut blooms. In the class for twenty plants in 8-inch pots, the judgment was reversed, Mr. C. Turner and Mr. G. Paul being first and second respectively, both having nice little specimens, that is to say, little in comparison with the plants just named. Messrs. Veitch & Sons also showed some well-grown plants in this class. In the amateur's class there were also some good plants.

Orchids.—Mr. Denning staged a fine group from Lord Londesborough's collection, including a blooming plant of the Cow's-horn Orchid (*Schomburgkia tibicinis*), a common plant; but one that rarely flowers in our collections. Sir R. Schomburgk found large masses of this fine plant in Honduras; but its large horn-shaped pseudo-bulbs were infested with ferocious ants, in such quantities as to render obtaining specimens a matter of considerable difficulty. It bears rosy-lilac flowers on the apex of a scape 3 to 4 feet high. A plant of *Odontoglossum retusum* bore a fine branched spike of deep orange flowers, very distinct, and not unlike a *Mesospinidium* in habit and general appearance. A good specimen of *Lælia majalis* (the Flor de Mai, or May Flower of the Mexicans) bore three very fine flowers. This plant is common; but rarely flowers, except in one or two collections. This group also included well-bloomed plants of *Dendrobium Parishii*, *D. Jamesianum*, contrasted with its nearest relative, *D. Infundibulum*; *Epidendrum Ibaguense*, bearing numerous spikes of bright rosy-lilac flowers; *Leptotes bicolor*, a pretty little Orchid when well-grown; and *Masdevallia Harryana*, very richly coloured. An extra prize was also awarded to Messrs. Veitch & Son for another fine group, including a fine specimen of *Odontoglossum nævium*, *Cypripedium lævigatum*, a splendid specimen, with four spikes, bearing in all fifteen flowers. The flowers are smaller and darker than in the case of *C. Stonei*, which, in general habit, it closely resembles, and further differs in its scapes, ovaries, and sepals being densely set with short hairs. A fine variety of *C. caudatum* bore three fine flowers with remarkably long tails; and a plant of *Aërides Fieldingii* bore five fine branched spikes. Mr. Williams and Messrs. Rollisson also had fine plants in their collections.

Azaleas.—These were rather small, the best collections coming from Mr. Charles Turner and Messrs. Ivery & Sons, of Dorking. The first-named exhibitor had naturally trained half-specimens, well-flowered, of *Grandis*, a fine rosy-scarlet; Madame A. Verschaffelt, a fine mottled flower; Duc de Nassau, rich purple-lilac, and others. Messrs. Ivery had closely-trained plants, compact and well-flowered, the best plants being Donna Maria, salmon, white edge; Flower of the Play, white; Reine des Pays-Bas, a fine rosy-lilac; and Roi des Doubles, a fine deep rosy variety. Messrs. Jackson & Son had a neat group of well-flowered plants. In the Amateur Class for Azaleas, in 12-inch pots, Mr. G. Wheeler staged a nice group, the best being *Concinna*, a fine lilac-purple; *Modèle*, bright rose; Duc de Nassau and Magnet; and, in the Open Class, Mr. Charles Turner had some well-bloomed specimens trained as standards. Messrs. Ivery & Son also staged a miscellaneous group of small plants, remarkably well flowered. Messrs. Veitch & Son sent a new bright rosy variety, named Mrs. Scorer.

Florists' Flowers.—These were well represented, especially in the case of collections of *Calceolarias*, staged by Messrs. Dobson & Son and Mr. James; the collection of the latter exhibitor, however, looked rather dull on account of an absence of light-coloured varieties. Mr. Rapley also had a fine group. The best plants exhibited were remarkable for their dwarf compact character, the flowers and foliage being extremely fine and well-coloured. Messrs. Jackman and Sons staged some fine examples of some of their best hybrid *Clematis*, and these were much admired. Auriculas were not so good, as their season is now past, the

best, however, came from Mr. Charles Turner, who had Colonel Champney, one of the best green-edged varieties, Fletcher's Ne Plus Ultra, and others. In the class for Alpines, Mr. Turner and Mr. R. Dean had nice collections. Messrs. E. G. Henderson staged two baskets of the finest *Mimulus* we have ever seen, the flowers being extra large, of good substance and richly coloured.

Table Plants.—These constituted one of the most interesting features of the show, and some excellent groups were staged by Mr. Wimssett, Mr. Bull, and Mr. Hudson, the prizes being awarded in the order named. The first named exhibitor had *Aralia Veitchii*, *Pandanus Veitchii*, *Croton undulatum*, *Adiantum Farleyense*, *Cocos Weddelliana*, *Dracenas*, *Thrinax gracilis*, and others equally elegant. In the second group we noted *Aralia leptophylla*, *Dracæna Gemma*, a dwarf plant with curious hairy foliage of a bronzy-green and rich deep crimson, *Croton Wisemannii*, *Curculigo recurvata variegata*, *Dracæna Guilfoylei*, and *Dæmonorops plumosus*, one of the most elegant of all table Palms when in a small state. Mr. Hudson's group comprised elegant examples of *Cocos Weddelliana*, *Casuarina sumatrana*, a graceful feathery plant of the freshest green imaginable, *Dæmonorops fissus*, *Euterpe edulis*, and others equally graceful.

Miscellaneous Subjects.—Fine groups of decorative plants, Ferns, and Orchids came from Messrs. Veitch, Bull, Williams, Cutbush, Rollisson, Parker, Aldous, and others; and fine collections of hardy herbaceous plants came from Mr. R. Parker, of Tooting, and Mr. R. Dean, of Ealing.

Fruit.—Splendid Strawberries came from Mr. E. Bennett and Messrs. Munro and Wilkinson, of Potter's Bar; and Mr. Miller, of Clumber, sent a box of British Queen. Mr. Clayton sent a fine box of Hepper's Goliath Tomato, a fine smooth fruit, of large size. A dish of the Chinese Kumquat (*Citrus japonica*) came from Knypersley, and was much admired.

First-class Certificates were awarded to the following:—

Hæmanthus Cooperii (Henderson).—This is a tall-growing species, fully a yard high, having glossy foliage, and dense heads of deep orange-coloured flowers, the most conspicuous portion of the latter being the anthers.

Pelargonium Duchess of Edinburgh (Braid).—A dwarf compact habited plant, belonging to the fancy or show groups, having dense clusters of crisp-petalled white flowers, the segments blotched with purple. It is a most profuse bloomer, and promises to be extremely useful for market work.

Adiantum gracillimum (Williams).—This is an extremely elegant form of the common wedge-leaved Maiden-hair, and is very useful for bouquets and other cut floral decorations, as well as for general cultivation as an ornamental Fern.

Aquilegia leptoceras lutea (Douglas).—The plant shown closely resembles the figure in the "*Botanical Magazine*" [6,073] and is, in all probability, the same plant. It has rich yellow flowers sweetly perfumed, and is one of the finest plants in the genus, and should be planted as a worthy companion to the blue-flowered *A. glandulosa*. It was introduced by Messrs. Backhouse from California.

Viola White Swan (Dean).—This is a fine creamy-white flower and will doubtless prove servicable for spring bedding.

Tea Rose Duchess of Edinburgh (Veitch).—This is an anomaly in its class, its flowers being of a deep rich lilac-purple, while the odour which is generally marked feature in Roses of this class, is in this instance scarcely perceptible. It has a good habit, and is to be recommended on account of its rich colour.

Gymnogramma triangularis (Williams).—This is an elegant little Fern, and has previously been alluded to in our columns.

Clematis Robert Hambury (Jackman).—Another good addition to this fine group of decorative plants.

Mammillaria Roezlii longispina (Croucher).—This is a strong-growing globular species, having white spines and rich crimson flowers.

Agave filifera superba (Croucher).—This is a dense-growing plant and a nice addition to its class.

Azalea Mollis v. Alphonse Lavelle (Lane & Son).—A fine sweetly-perfumed variety belonging to the hardy section.

Hypolepis Bergiana (Rollisson).—This fine Fern has been previously described in our columns.

Hybrid *Mimulus* (E. G. Henderson).—This is a fine strain, the flowers being of large size, and richly spotted with bright crimson on a yellow ground.

CRYSTAL PALACE.

MAY 9TH.

Owing to a change of date on account of the Czar's projected visit to the Palace, and the unavoidable absence of one or two of the principal exhibitors, this show was scarcely so good as usual, although some classes, as, for example, those in which the Roses and stove and greenhouse plants were placed, were well represented, the former being, perhaps, the most attractive feature of the exhibition.

Stove and Greenhouse Plants.—The best collections were staged by Messrs. Jackson & Son, of Kingston, and Mr. J. Ward, of Leyton, who represented the nurserymen and amateurs respectfully. The first-named collection consisted of twelve well-grown and, what is of equal importance to an exhibitor, well-shown plants. They consisted of *Pimelea Hendersonii*, an old favourite, and, in this case, a remarkably effective one, forming a dense mass of bright rosy flowers, fully 3 feet through. The specimen of *Erica Cavendishii* in this group, although by no means the largest plant in the show, was by far the best, its foliage being of a rich deep green, and its golden flowers remarkably fine and well-coloured. *Imantophyllum miniatum*, one of the best of all Amaryllidaceous plants for exhibition purposes, was represented by a fine plant, bearing at least twenty-five trusses of orange-scarlet or vermilion-coloured flowers; and a plant of *Aphelaxis macrantha purpurea* was a perfect picture of health and floral beauty. There were, too, *Draco-*

phyllum gracile, a good plant, either for show purposes or cut bloom, and a fine *Erica Victoria*, well bloomed, in addition to good plants of *Clerodendron Balfourii*, *Genethyllis tulipifera*, and one or two good *Azaleas*. Mr. Ward's group also consisted of well-finished plants, including a good *Boronia pinnata*, an old, but effective, plant, which, when well-grown, bears numerous deep rosy-lilac flowers, set off by elegant finely-cut foliage. *Genethyllis* (*Darwinia*) *Hookeri*, in this group, was a nice plant, its flowers being numerous and richly-coloured, a sure indication that it had been well treated and accustomed to plenty of light and air. Two fine *Ericas* graced this collection, one being *E. Cavendishii*, about 4 feet by 4, and the other a fine *E. depressa*, about 3 feet by 3. The last-named plant was a picture of health and vigour, its characteristic sombre-tinted foliage hanging over the sides of the pot, both examples being well flowered. *Genethyllis tulipifera* in this group was also well flowered, as was likewise a large specimen of *Statice profusa*, about 4 feet high, and 3 feet through. This is, when well finished, one of the best of all blue-flowered exhibition plants, yet it belongs to a genus rarely represented at exhibitions, although several of its members are well adapted for such purposes. A specimen of the scarlet *Anthurium* bore at least twenty of its brilliant spathes. Mr. B. S. Williams, of the Holloway Nurseries, showed a nice group in the nurserymen's class, in which was a splendid specimen of *Acrophyllum venosum*, a fine plant, both as regards foliage and flower, and one that few but the very best plantmen succeed in growing into a presentable specimen. Mr. Williams had also a good *Genethyllis tulipifera* remarkably well flowered; also *Aphelaxis macrantha purpurea*, well coloured, *Erica Victoria*, and a fine specimen of *Anthurium Scherzerianum*, bearing thirty fine richly-coloured scarlet spathes. This plant is a broad-leaved variety, and closely resembles the one which Mr. Baines used to show so well. Mr. W. Kemp showed a nice group from the Duke of Northumberland's collection at Guildford. The most conspicuous plant in it was *Adenandra fragrans*, a fine old exhibition plant; it had fresh green foliage, and a profusion of pink flowers, each as large as a shilling. The same collection also included a good plant of *Chorozeum Henchmannii*, covered with its deep rosy-scarlet flowers. Mr. Peed's collection contained well-grown plants of *Erica Cavendishii*, *Allamanda grandiflora*, well flowered, but it, together with several other specimens appeared to have suffered from cold during transit, and *Clerodendron Balfourii*. In the amateur class were also some good plants.

Pot Roses.—These were very good, some of them being fully 5 feet high and as much in diameter, and profusely covered with fine flowers. Mr. G. Paul, of Cheshunt, and Mr. Charles Turner, of Slough, were equal first. The latter had Victor Verdier, deep rose; Madame V. Verdier, crimson; Souvenir de la Malmaison, fine blush; Juno, rose; Charles Lawson, deep rose; Duke of Edinburgh, crimson-purple; Souvenir d'un Ami, fine flesh; and the old favourite Anna Alexieff. Mr. G. Paul had Dr. Andry, crimson-purple; Charles Lawson, Anna Alexieff, Princess Mary of Cambridge, blush; Horace Vernet, deep crimson-purple; Celine Forestier, lemon-yellow, very fine Noisette; Theresa Levet, fine deep rose; John Hopper and Madame de St. Joseph, fine flesh-coloured Tea. In the amateur's class Mr. Moorman and Mr. E. Ellis both staged fresh well-bloomed specimens. One of the great attractions of the show was the magnificent collection of cut blooms staged by Mr. W. Paul, of Waltham Cross. These consisted of Maréchal Niel and other fine varieties, and, throughout the day, were surrounded by a throng of admiring visitors, thus affording a pleasing assurance that the charms of the Floral Queen are yet unrivalled.

Florists' Flowers.—*Pelargoniums* were well shown by Messrs. Dobson & Sons, and also by Mr. James, both growers staging dwarf fresh, and well-bloomed plants. *Calceolarias* were also well represented by a good strain from Messrs. Dobson's collection. Mr. Hooper, of the Vine Nursery, Bath, had a group of *Ranunculus*, and some fine *Pansies* belonging to the show and bedding sections, were staged by Messrs. Dowrie, Laird, & Laing, and Mr. James, of Isleworth. Messrs. Jackman staged three or four dozen of their new hybrid *Clematis*, very profusely flowered, and they formed a striking and effective feature in the show.

Orchids.—These, on the whole, were very poorly represented, the best collections coming from Mr. B. S. Williams and Mr. J. Ward, of Leyton. The former had good specimens of *Vanda tricolor*, *Cypripedium villosum*, *Cattleya Mossiae*, still one of the best of all Orchids; *Cypripedium caudatum*, with very long petals; and a fine plant of *Aëride Fieldingii*. In Mr. Ward's collection, we noted one of the best plants of the delicate little *Odontoglossum Phalaenopsis* that we have ever seen. It was fresh and vigorous, bearing about fifty of its white and rosy-purple flowers. In addition were *O. Pescatorei*, with three or four good spikes. *Cypripedium villosum*, a free-growing species, with glossy-brown flowers. *Dendrobium nobile*, and *Lycaste Skinneri*. The other exhibitors were Mr. Reed, Mr. J. Wheeler, Messrs. Jackson & Son, and Mr. Edward Morse.

Miscellaneous Subjects.—Three fine specimens of *Echinocactus visnago* were staged by Mr. J. Croucher from the collection of J. T. Peacock, Esq., of Hammersmith. Mr. W. Paul had a dozen *pyramidalis* specimen *Ivies*, both green and variegated. These were very effective and much admired. Messrs. W. Cutbush & Sons staged a very effective group of ornamental stove and greenhouse plants, as did also Mr. B. S. Williams, the latter collection including new and rare kinds. Messrs. Dick Radclyffe & Co. exhibited half-a-dozen Fern cases for window or drawing-room, these being very tastefully filled with Ferns, Palms, and other decorative plants; and Mr. Vote exhibited several of his patent garden frames, remarkable for their ingenuity and useful alike to the professional and amateur cultivator.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

GARDEN FERTILISERS.

By THOMAS BAINES.

THERE are few matters connected with a garden, whether large or small, of greater importance than manure; and there is nothing in which gardeners are so often reduced to severe straits, as they are, through an insufficiency in the supply of this all-important element to success in the cultivation of vegetable crops. This does not so much apply to small or moderate-sized places, as it does to those of greater extent. In many large establishments, where the gardener has every load of dung meted out to him, with a grudging hand, through the farm bailiff or agent, he stands much in the same position as the Israelites found themselves in the Egyptian captivity, of being required to burn bricks without stubble, and yet he is held responsible for the accomplishment of an equal impossibility. The man who cultivates his broad acres on the farm has the advantage over the gardener that his opportunities for change of crops are much greater, and the elements they extract from the soil, in the process of development, are so different in the cereals, grasses, and roots, that, through skilful rotation, he is enabled to make shift with much less manure per acre over a series of years than the gardener can possibly do with. The greater number of the crops which the gardener has to grow, in many instances from ground that has produced the same things for scores of years, vary little except in degree as to the elements they require for their sustenance; the difference laying principally betwixt deep-rooting and surface-rooting plants. Strawberries and bush fruits may be held as some exception, but the breadths they occupy in private establishments are comparatively small, and, with the exception of Strawberries, cannot, with advantage, be often changed. During the present century the chemical researches and experiments, with respect to manures, of Liebig, Lawes, and others have done much to enlighten the world upon this subject, and have also pointed out to us how ruinously wasteful our practice, as a nation, has been, not alone in the matter of the sewage with which we have polluted almost every river and stream in the kingdom, but also in the case of our wasteful proceedings in the preparation of manure; in this latter, gardeners have, in many instances, either unwittingly, or, in some measure, through necessity, been accessory to the general waste. Before hot-water was extensively introduced as a heating medium to plant and fruit structures, more especially pits and frames, hot dung was the principal material employed, and then, as now, the preparation was highly destructive to the essential constituents of the manure, more especially as regards its richest element—ammonia, which, as is known by nearly every gardener, is dispelled by the heat in the process of fermentation. Through the preparation it has undergone, old hot-bed manure often holds, relatively as to strength, a similar value that brewers grains holds to good malt, most of the best fertilising elements being gone from it through violent heating; this, to some extent, will occur under the best of management, but when the manure is not allowed to lay too thick, sufficiently often stirred, and mixed with half-rotten leaves, the loss which it sustains is reduced to a minimum. When guano was first introduced the prejudice against it was so great, not only amongst the farmers, but also amongst gardeners, that many were slow to either try it or admit its fertilising properties; this was, in some measure, attributable to the frauds perpetrated through its adulteration; and, even, at the present day, after some forty years' trial, this, the richest of all ammonical manures, is insufficiently known or appreciated by many gardeners. Great numbers of plants, like ourselves, thrive best upon a mixed diet; and I never yet met with a quick-growing plant, from a Rhubarb root to a Raspberry cane, that was not benefited by the judicious use of guano. As an experiment, I once gave a liberal dressing of this manure to a Raspberry plantation that had stood for thirty-seven years from the time of its formation, and which was in

a very weak state, the canes not running more than 4 feet in height, and correspondingly thin. With nothing but the guano applied in the beginning of April, and a light surface dressing of leaf-mould, the canes grew from 7 to 8 feet in height, and proportionately thick, bearing an enormous crop the following year. By an alternate yearly dressing of guano and farm-yard manure, they have, for some years, kept on doing as well as any plantation I ever saw, of only a few years standing. Even Strawberries, when not sufficiently strong, are benefited by a moderate application after the fruit is gathered, but, with these, care must be taken not to overdo the dressing, or the plants will make too much growth to ever ripen the crowns properly. Currants and Gooseberries, where at all poor, are much improved by it. There is one thing that I scarcely expected to find, and that is, they have no tendency to wear out, or become exhausted, by its use. All the Brassicas, Carrots, Turnips, Peas, Beans, and, more especially, Lettuce and small salads, are greatly benefited by it. This, to some, may look like the repetition of a very old story, but we meet with numbers of gardeners who are at their wits ends for an adequate supply of manure, and yet who have never used this or any other description of what may be called light fertilisers, except in, perhaps, some experiment that was insufficient to determine their value. I do not mean to say that farm-yard manures can be done without, quite the contrary, but, to all who labour under a short supply of these, I would say, make up the deficiency with guano, nitrate of soda, or sulphate of ammonia, changed according to the character of the soil, or the particular element in which it is found deficient, for the particular crop it is under. For old gardens that have been manured continuously with farm-yard dung, heavy dressings of leaf-mould and other vegetable soil, I much prefer the use of a portion of some light manure to that which is of a heavy nature. One great advantage which these concentrated manures possess is their immediate action. Where a scarcity of dung existed at the time of preparing the land or putting in the seed, assistance can be given, in this way, to the crop in its after stages, as occasion may require. In the case of culinary vegetables on strong retentive soils, there is no better way of applying these light manures than that of sowing them broadcast over the land before digging, and working in with, whatever portion of dung is used. By this means the manure is dispersed through the body of the soil, in which the roots ramify, meeting with food in whatever direction they extend. On light surface soils, or where the sub-soil is of a sandy or gravelly character, light ammonial manures should be applied on the surface, when the crops are in active growth, for the obvious reason that they are soluble in water, and unless the roots are in a state to at once absorb the essence of the manure held in suspension, the descending rains carry it deep down into the hungry substratum out of their reach, and so it gets lost. On all such soils as these, heavy dressings of manure, of whatever description, are a mistake, for the land is not of a nature to hold it longer than the requirements of a season's growth; and when the autumn and winter rains descend it is carried away. All experience leads to the conclusion, that manure, of whatever description, is the quickest in its action when applied in a liquid state, consequently, when any crop gives evidence of an insufficiency of support, there is nothing so effectual as liquid manure, this in particular applies to kitchen-garden crops, where the necessary application is practicable. In fact, there are some vegetables that, in their more advanced stages of growth, can be brought to a perfection by the use of liquid-manure, that could not have been arrived at by any application of manure previous to planting, without inducing plethora. The French summer salads that are held in equal estimation with those they produce in winter, owe their excellence largely to the rich liquid with which they are unstintingly supplied. Lettuces, Radishes, and even Mustard and Cress, that are grown quickly by the use of liquid-manure, are as different as can well be imagined from the tough, flavourless, undigestible stuff of which an English salad is too often composed. The comparatively large plants in the smallest of pots, unsurpassed in their way, which the growers for Covent Garden Market turn out, are telling examples of what may be accomplished by means of liquid-manure alone.

NOTES OF THE WEEK.

— THE dismal character of May, up to the present time, has not made Covent Garden much less attractive than usual at this time of year, though the supplies have been considerably affected by the cold. Good samples of English Peas are now in the market, the produce of Somersetshire. Tomatoes are visible on many stands, forced, and from Algiers; Cherries have come in considerable quantity from Algeria and the south of France; a small cargo of excellent Pine-apples arrived from the Azores during the week. Peaches (forced) are plentiful and have been obtainable since the middle of April. In the case of Grapes our forcing-gardeners now produce them all the year round; Melons, English grown, are to be had of good quality; and also Figs and Nectarines, both the produce of hot-houses. New Potatoes arrive in large quantities from the Channel Islands, and some of good quality have come from Lisbon of late.

— GAILY decorated as was the Crystal Palace on Saturday last, it contained nothing of more interest, even to royalty itself, than Mr. W. Paul's exhibition of Roses, including, as it did, not only a formidable array of old and well tried favourites, but also many new varieties, worthy additions to the court of the Queen of flowers, raised at Waltham Cross. These were all skilfully and effectively grouped along with specimen Ivies, Acers, variegated Oaks, and other hardy trees and shrubs of a highly decorative character.

— THE council of the Royal Horticultural Society telegraphed on Tuesday last to the President of the Tuscan Royal Horticultural Society, to propose that an international show be held in 1876. In the event of the proposition proving acceptable, the council will at once take steps to organise a joint committee representing the society, the Royal Botanic Society, and other leading horticultural bodies, should they be willing to lend their assistance. The council also propose that the Royal Horticultural Society should hold a dinner this year in the latter part of June. The prices of tickets and other details will be notified as soon as possible, and, if practicable, the dinner will take place at Chiswick.

— SEVERAL interesting herbaceous plants have recently been in flower at the Exotic Nursery, Tooting. Among them may be mentioned the beautiful *Omphalodes Luciliae*, a glaucous-leaved species, with pale-blue flowers; *Aquilegia cærulea*; nice plants of *Cheiranthus Dillenii*, which bears brownish-yellow blossoms in profusion; and *Anthyllis erinacea*, a quaint-looking spiny shrubby species, about 6 inches high, with purplish-blue pea-like flowers, produced in tolerable abundance. We also noticed a good plant of the double variety of the Cuckoo Flower (*Cardamine pratensis*), an old, but somewhat seldom-seen, plant. This was growing on a moist bank—a position that fully answers its requirements.

— ALTHOUGH many plants are suffering from the inclemency of the weather, a considerable number of highly attractive subjects is now in flower at the Hale Farm Nursery, Tottenham. Foremost among these are the American Cowslips (*Dodecatheons*), of which great numbers are in full flower, particularly the dwarf deep rose-coloured *D. integrifolium* and the distinct-looking *D. Jeffreyanum*. The double variety of the scarlet-blossomed *Geum chilense* is very conspicuous in one of the borders, as are also fine specimens of the yellow-flowered *G. montanum*. The pretty dwarf light rose-coloured *Iberis jucunda* is in bloom, and a large tuft of *Onosma taurica*, has an abundance of pale yellow flowers. *Scabiosa montana*, just beginning to produce its purplish flowers, promises to become an attractive plant; large masses of our well-known spring-flowering plants are in bloom here.

— MR. BAILEY DENTON, in a letter to the *Times*, remarks that in the winter just passed the rainfall has been very considerably below the average, though not so much less, as the previous winter had been more than the average. In the eastern counties—the driest part of the country—for instance, the quantity of rain that fell in the six months from October, 1872, to March, 1873, inclusive, was 21½ inches, while the amount due to the same period last winter, 1873-4, has barely reached nine inches. The mean of many years is somewhat above 13 inches. Comparing this mean with the rainfalls of the last six winters (in the eastern counties) we shall see (proceeds Mr. Denton) that although we have had within that period two singularly dry years, the fall of this last winter (nine inches) was less than any.

— THE English edition of the *Illustration Horticole*, for April, contains excellent figures of the following choice plants, viz.:—*Carludovica imperialis*, an elegant plant, closely resembling in general appearance some of the *Geonomas*, but, in reality, belonging to the *Cyclanthaceæ*. It has dark green bifid foliage elegantly recurved, and will prove an ornamental addition to stove plants. Of *Oncidium sarcodes* there is a good figure, evidently made, however, from a pale-flowered variety. It is probably only a good variety of *O. amictum*—and in habit is identical with that species, *O. pubes*, *O. cruci-*

gerum, and one or two other species. We have seen this plant with 100 flowers on a spike 4 feet long. *Dieffenbachia lancifolia* is a narrow-leaved plant blotched with pale green on a darker ground. It is an elegant addition to a useful genus of foliage plants.

— THE old-established firm of Osborn and Son is, we find, turning its attention to matters of decoration. Those at the Foreign Office, when it was visited by the Czar, were, we are informed, done by Messrs. Osborn.

— ON the rock-work at Kew, which has been rebuilt, and the planting just finished, several plants are conspicuously in bloom, and among them may be named *Erodium petraeum*, *Anthyllis montanus*, a pretty dwarf species, admirably adapted for such positions, and a vigorous composite called *Craspedia Richea*, a plant which bears a large round head of yellow flowers.

— THE Americans have introduced a Silver Occidental Arbor-vitæ (*Thuja occidentalis argentea*), which they name Victoria, and which is described as a curious and beautiful dwarf plant, wholly unlike any hitherto described, being of a fresh green colour, with the branchlets distinctly tipped with white, entirely hardy, and most attractive and pleasing in appearance.

— A FINE hybrid *Phyllocactus*, is in flower just now in Mr. Peacock's collection of succulents at Sudbury House, Hammersmith. It somewhat resembles *P. Corderoyi*, but differs from that kind in colour, which is a delicate satiny-rose. Even in the case of a small plant the flowers are so large and showy as to clearly indicate that, when better grown, it will stand in the first rank amongst what are termed tall Cacti.

— CHRYSANTHEMUM CATANANCHE, a plant brought, we believe, from Morocco, has lately been in flower in a frame at Kew. Its foliage somewhat resembles that of some dwarf *Artemisia*, and the flowers are about the size of those of *Catananche cærulea*, but of a white or sulphur colour, with a dark ring outside the disk. We also noticed in a frame in these gardens *Phlox bifida* a plant resembling *P. divaricata*, but with narrower foliage, and petals narrower and more distinctly two-parted than those of that variety.

— AMONG recent additions to the floral attractions of Covent Garden, we may direct attention to the beautiful specimens of *Ixias* now being exhibited by Messrs. Hooper in the Central Row. These vary in colour from faint rose and white to rich crimson-purple, while one form has flowers of a peculiar metallic green. The blossoms are borne on slender spikes and are well adapted for purposes of indoor decoration. These *Ixias* are imported from the Channel Islands.

— AT the exhibition of the Royal Botanic Society on Wednesday last, a plant of *Dendrobium Falconeri* was exhibited from the collection of D. Hanbury, Esq., The Poles, Ware, bearing some fifty large richly-coloured flowers. The plant, which was not a large one, was the best-bloomed specimen, for its size, which we have ever seen. It is a plant which, during the growing season, likes a good supply of water; but after it has finished growth, which is by autumn, it should be kept rather dry till it begins to show flower, but it must never be allowed to suffer from want of water, as it frequently grows during the winter months. Under this treatment it well repays the trouble that is taken to induce it to produce its charming white and purple flowers.

— M. LINDEN has received, says the *Illustration Horticole*, three new species of *Masdevallia* from M. Roezl, who discovered them in northern Peru. They are, *M. melanopus*, having white flower-tubes, and very dark ovaries and tails; *M. caloptera* having larger, probably white, flowers, with dark purplish or violet longitudinal stripes on the sepals—two on the upper sepal and three on each lateral one; and the highly curious *M. polysticta*, bearing spikes of seven or eight pale or white flowers, with numerous dark brown spots. M. Roezl found tufts of this species bearing twenty flower-spikes at the same time. These additions to this peculiar and interesting genus will give a fresh impetus to the favour in which these plants have been held during these last few years, both in this country and on the Continent.

— NOT only are the directors of the Alexandra Palace Company fortunate in possessing a fine building and a beautiful park, but the internal arrangements of the palace promise to be on an equally grand scale. Flower and fruit shows will be occasionally given, and certain portions of the building are to form a perennial horticultural exhibition of a high character. In conservatories and under glass domes, of great beauty and lofty elevation, hundreds of magnificent greenhouse plants will find a home. Palms of great size, and other tropical plants, have been given to the company by many distinguished lovers of horticulture. Mr. Peacock, of Hammersmith, has arranged to transfer to the palace a duplicate collection of his Agaves and Cacti, in the formation of which he has spared neither time nor money; and this example will, no doubt, be followed by other liberal gifts of choice collections, making this department of the palace equal to anything of the kind in the country.

THE GARDEN IN THE HOUSE.

FLORAL DECORATIONS AT THE CRYSTAL PALACE.

THE decorations on Saturday last (the 16th inst.) in honour of the Czar's visit to the Crystal Palace, were of a very tasteful character, the saloons being carpeted with crimson baize, and fringed with banks of the choicest flowering and foliage plants. Among these were Palms, Cycads, Ferns, Azaleas, Clematis, Roses, and other plants, while hanging baskets overhead were decorated with the gracefully pendant branches of the Golden Cobæa, Ferns, Selaginella, and other exotics. The staircase leading to the royal saloon and private box was divided in the centre by means of a ribbon design, composed of Golden Feather Pyrethrum and purple Iresine, the column at the top being gracefully wreathed with Clematis profusely covered with great lilac and satiny white flowers. The semi-circular front of the royal box was fringed with fresh green Selaginella growing in small pots, the latter, of course, being concealed, and on the Selaginella were laid clusters of Spiræa, Lily of the Valley, double pink Pelargoniums, and Eucharis flowers, the whole forming a charming contrast with the heavily gilt and crimson-velvet lined furniture. The chief point of attraction, however, was the saloon immediately behind the box itself, the decoration of which was entrusted to Miss Annie Hassard, whose taste in such matters is well known. The main features consisted of three handsome vases of parian and porcelain ware beautifully modelled, and the medallions at the base were very gracefully designed. These Miss Hassard rendered still more beautiful by using them as receptacles for the choicest of flowers and the most graceful of foliage, the bright glowing colours of the one being toned down and artistically blended by the judicious contrast of the other. The largest of these vases was about 2 feet high, and its rim and pedestal were gracefully draped with fresh green fronds of *Pteris serrulata*, and the still more elegant spray-like drapery of *Lygodium scandens*. Above this, and resting on the rim of the vase itself, were choice Rose blooms, consisting of *Maréchal Niel* (golden-yellow) and the exquisitely-tinted roseate-hued *La France*, the two alternating with each other, the line being broken here and there by the introduction of flowers of the *Æthiopian Lily*. These were the largest blooms used, and formed a foundation for smaller and still more elegant blossoms. These consisted of sprays of rosy and white *Rhodanthe*, the flowers of the latter glistening like frosted silver or the richest of satin fabrics. Mingled with these, and rising as naturally from the vase, as if growing, were feathery sprays of the white *Spiræa japonica*, common wedge-leaved *Maiden's-hair*, and a stem or two of the gracefully-arching *Solomon's Seal* (one of the most attractive of all hardy plants, so far as form is concerned)—these were added with excellent effect, the whole forming a very beautiful group. In addition to the above, two smaller vases were tastefully filled with the fresh green fronds of *Pteris cretica albo-lineata* and *Adiantum cuneatum*, among which were grouped clusters of pearly *Stephanotis* and *Lily of the Valley*, *Pelargoniums*, *Ericas*, and *Spiræa japonica*. These occupied positions on the side-tables; and, with the addition of a few graceful *Dracenas* and other plants, made one of the most charming arrangements we have ever seen.

Duration of Cut Flowers.—This spring I have carefully noted the time during which some of the most showy of early-blooming plants retain their beauty when cut, and I find the *Narcissus* amongst the most durable. This, if cut when the buds are fully developed, opens out beautifully in water, and lasts in flower, on an average, nine or ten days. One species, *N. gracilis*, lasted sixteen days, and was not much withered even at the end of that period. The blossoms of the German *Iris* contrasts well with those of the *Narcissus*, and if the spike is cut with the first flower expanded, the other two or three unopened buds will follow in succession, causing the same spike to last fully a fortnight. *Solomon's Seal* keeps fresh for a week or ten days, and sprays of *Forget-me-not* even longer if arranged either in damp sand or Moss. Squills, such as *Scilla patula*, *S. campanulata*, *S. cernua*, and their varieties, also last long indoors; the flower-spikes turn upwards, and the flowers open almost as well when cut as when on the plants themselves—B. J. I.

WORK FOR THE WEEK.

FLOWER GARDEN AND PLEASURE GROUND.

By PETER GRIEVE, Culford Gardens.

THE present spring, which is now merging into summer, succeeded a remarkably mild winter; consequently, vegetation generally had acquired undue earliness, which, in many instances, has been severely checked by the long-continued drought, and inclement character of the latter part of the spring and early summer. Even now the weather is remarkably cold, and hardly a night has passed without frost, of more or less intensity. This degree of cold, therefore, combined with drought, has, of course, been unfavourable to the display of spring flowers, and has induced early-flowering Tulips, &c., to pass out of flower much earlier than usual, while tolerably hardy spring flowers, such as the beautiful *Myosotis dissitiflora*, have suffered severely from the effects of the late frosts. Other species of spring flowers, however, such as *Aubrietias*, which possess, in a greater degree, the power of resisting cold as well as drought, have for some considerable time been exceedingly attractive, and will, no doubt, continue in excellent condition for some time to come, where they can be allowed to remain undisturbed; but, in many instances, this will not be the case, for, as regards the parterre, the time has arrived when spring-flowering plants and bulbs of various sorts must be removed into the reserve garden, in order to leave the beds at liberty for summer-bedding plants. This removal, however, must be effected with the greatest possible care, allowing as much soil as possible to adhere to the roots; and the planting should be immediately followed by liberal waterings, and shade from bright sunshine until the plants have become again fairly established in their fresh quarters. In cases where it may be desirable to increase any of the varieties of plants used for spring bedding, such as *Aubrietias*, *Daisies*, *Forget-me-nots*, *Polyanthuses*, *Primroses*, *Pansies*, *Violas*, &c., this can now be done by division and planting in a shady situation in the reserve garden, or under a wall; while cuttings of *Wallflowers* and similar plants may be inserted under hand-glasses, and should, when fairly rooted, be planted out in beds in the reserve garden, to be in readiness for again furnishing the beds in the parterre, &c., when summer-bedding plants have again passed away. As soon as the spring-blooming plants have been removed, the empty beds and borders should have their margins carefully regulated, and to the soil should be given a liberal application of manure, or some suitable material, such as fresh soil of good quality. This should be well incorporated with the original soil by deep digging; and, in supplying fertilising materials to flower-beds, the nature and probable requirements of the plants intended to occupy them should, of course, have due consideration, as, for some species, the soil can hardly be too rich; while, for others, such as *Tropæolums* and strong-growing *Zonal Pelargoniums*, this is by no means desirable, as it tends more to the production of foliage than bloom.

The arrangement of the flower garden should always be decided upon during the previous summer, so that the material required should all be in readiness by the present time; and, supposing this to be the case, planting out ought to commence at once, beginning with the more hardy species, such as *Calceolarias*, *Verbenas*, *Zonal Pelargoniums*, &c.; while the first week of June is quite early enough to plant out the various varieties of *Tricolor Pelargoniums*, *Heliotropes*, *Coleuses*, *Iresines*, *Alternantheras*, &c. In planting the various beds in the flower garden, care should be taken to avoid a too free use of the primary colours, as few things can be more objectionable than large flat surfaces of bright scarlet and yellow, &c., unless the same is duly toned down by the inter-spersion of more quiet and pleasing shades, in the form of margins to beds and clumps of considerable dimensions; while anything like monotony may be greatly relieved by the judicious introduction of standard and pyramidal plants of various sorts, such as *Pelargoniums*, *Fuchsias*, *Cytisuses*, &c., together with plants of remarkable foliage, such as the *Acer Negundo variegatum*, *Abutilon Thompsoni*, *Dracenas*, *Palms*, and *Yuccas*; and nearly all the beautiful new *Clematises* form most ornamental objects when planted upon the turf and trained to wire arches or other tasteful devices. Annual flowers, which may have been sown in the open air, may now require to be thinned out; and others, sown under glass, such as *Asters*, *Stocks*, *Phlox Drummondii*, &c., will require to be carefully planted out in beds or borders where they are intended to flower. Very few annuals are suitable for furnishing the beds of the flower garden, on account of the short time during which some of the most beautiful varieties remain in perfection; but they are nevertheless, exceedingly useful as marginal plants for shrubby borders, and for planting in beds containing bulbs in the spring garden, with the view of rendering the beds gay when the bulbs have ceased to bloom; and a border devoted to the purpose of growing a

selection of the finest annuals forms an interesting and often a very attractive feature in a garden. Hardy herbaceous plants, many of which are exceedingly beautiful, should now have every necessary attention paid to them, such as thinning out the shoots, staking and tying up, removing decayed flowers, weeds, &c., while climbing Roses, Honeysuckles, Jasmines, &c., should be carefully regulated. In establishments where a hardy Fernery exists, and this, if properly managed and favourably located (in a situation not too much exposed to the sun), is a very interesting department; and, whether in the form of a root or rock-garden, must now have its share of attention as regards eradicating weeds of all sorts, removing decaying fronds, loosening the soil, and introducing young plants of the comparatively delicate sorts which it may be found necessary to keep, during winter, under glass. In the pleasure grounds evergreen shrubs may yet be transplanted if necessary, while the growth of others may be regulated by being cut in, so as to prevent strong-growing species from encroaching too much upon their more delicate and slower-growing neighbours. Box and other edgings may now be trimmed, and the Grass margins to walks, drives, and coach roads, &c., should also be regulated, or edged if this has not been already done. Plantains and other broad-leaved plants should now be carefully extracted from lawns and Grass belts; while the Grass should, in all cases, be kept level and short by the frequent use of the mowing machine; advantage, too, ought to have been taken of the long period of dry weather, which has in most localities been experienced, to stir up the surface of gravel walks, in order to thoroughly eradicate weeds and Moss, and when this has been accomplished, roll the gravel well down with a heavy iron roller, soon after the first heavy rainfall, and this rolling (if the gravel be of a good binding quality) will render the walks firm and comfortable; and to ensure a continuance of this desirable condition, throughout the season, an occasional application of the roller, soon after a heavy fall of rain, will be all that will be required.

COOL ORCHIDS.

By F. W. BURBIDGE.

MANY of these will now be making vigorous growth, and must not on any account be allowed to suffer from want of moisture either at the roots or in the atmosphere, as nothing tends so much towards checking their vigour and injuring the plants as sparsity of moisture when making their growth. Keep a sharp watch for red spider, thrips, and green fly. The two former are extremely fond of *Pleiones* and *Cypripedium Schlimii*, and the latter, if present, are sure to be found on the flower-spikes of other species. The red spider and thrips are readily kept in check by repeated spongings, and occasional fumigations with tobacco-cloth or rag will settle the aphides. It is not advisable to smoke Cool Orchids too vigorously, as it often causes *Odontoglossum* and *Miltonias* to shed their leaves prematurely. Give air freely, carefully guarding against cold draughts, and shade the plants from bright sunshine as may be required. Any species that have been resting, and are now starting into fresh growth, may be re-potted at once. *Masdevallias* will now be growing freely, and should be placed at the coolest end of the house, and syringed once or twice daily. *Cypripediums* and *Disas* are also benefited by being syringed occasionally. Some of the pots that are unsightly may be top-dressed with lumps of fibrous peat and fresh living Sphagnum, so as to give them a fresh and healthful appearance. Sphagnum, in a fresh state, is rather difficult to procure, especially in the south of England, while that which has been heated in sacks, and which has become lifeless, is of little service to the cultivator. The following plants, amongst others, are now in flower, viz., many beautiful forms of *Odontoglossum Alexandræ*, *O. citrosum*, *O. retusum*, *O. Lindleyanum*, *O. luteo-purpureum*, and others, *Masdevallia nycterina*, *M. Harryana*, *M. Lindenii*, *M. ignea*, *M. Veitchii*, *Epidendrum Ibaguense*, *Oncidium concolor*, *Ionopsis paniculata*, *Lælia majalis*, *Nasonia cinnabarina*, and *Ornithidium coccineum*.

HARDY FLOWERS.

By THOMAS SPANSWICK.

WITH bitter cold winds in the day time, and more or less frost at night, many hardy plants which would have been in full bloom had genial weather prevailed, have received such a check as will probably spoil their beauty for the season. Two fine-leaved hardy *Polygonums*, viz., *cuspidatum* and *sachalinense*, in the neighbourhood of London, have suffered considerably from spring frosts; as has also a fine specimen of the Official Rhubarb, at Kew (*Rheum officinale*). The latter promises to be, when more plentiful, a foliage plant fit to be associated with such noble leaved subjects as *Gunnera scabra*, *Rheum*, *Acanthus latifolia*, and plants of similar character suitable for position on turf or other prominent positions. Notwith-

standing the weather, however, there is a good display of bloom on many plants, as, for instance, the *Columbines*; than the varieties of common *Columbine* (*Aquilegia vulgaris*) there are no more valuable plants for purposes of general decoration, and they may be easily raised from seeds, which are cheap. *Iberis correaefolia*, probably the best of the perennial species, is just now coming freely into flower. It is a plant which forms a compact edging thickly studded with pure white flowers about mid-May, and when grown in pots it is equally ornamental. Several *Veronicas* are also nicely in bloom, prominent among which may be mentioned the pale blue flowered *V. gentianoides* and the dwarf dark blue *V. prostrata* and *pulchella*. *Lupines*, too, are now highly attractive; also *Thermopsis fabacea* and *lanceolata*, two yellow-blossomed ornamental leguminous plants, well worthy of general culture. Spring and early summer-flowering annuals have come so tardily into bloom this season that we miss the grand displays usually made about this time by such kinds as *Collinsia grandiflora*, *Saponaria*, *Collomia*, *Limnanthes Douglasii*, *Nemophilas*, and others, raised from seed sown in the open ground in autumn. Little advancement has been made in the planting out of annuals from pots, on account of the dryness of the weather and coldness of the winds, but as soon as rain comes they should be planted out with as much expedition as possible. Early-flowering hardy bulbs may be taken up, if necessary, to make room for summer-flowering plants; but, except in the case of rare kinds, this is not at all a commendable practice. Seedlings of perennials sufficiently advanced for pricking off should be attended to, and any choice additions made to collections of herbaceous plants should be looked after, and, if necessary, increased by means of division, or, if this is not practicable, cuttings should, if possible, be taken off and inserted in pots.

HARDY FRUIT AND KITCHEN GARDEN.

WHERE Apricots, Peaches, and Nectarines have been protected, the coverings will want gradually taking off, so that the trees may not suffer from too sudden exposure. Disbudding the shoots, by only taking off a few at a time, till all danger from the influence of cold weather is over, must now or soon be proceeded with. Apricot trees are often much infested with a grub, which curls the leaves up and eats the young fruit. As this pest is safe from syringings or dressings of any kind, it must be searched for and crushed with the finger and thumb; and the more effectually this is done, the fewer grubs will appear next year. In the kitchen garden, Brussels Sprouts, Savoys, and Cauliflowers should be transplanted into deeply-worked, well-manured soil. Another plantation of white Paris Cos Lettuce should be made. The ground intended for the main crop of winter Greens and Broccoli should be prepared by well manuring and deeply digging it. These crops generally succeed Celery, autumn-sown Onions, Parsnips, or early Cabbages, as may be most convenient. New Zealand Spinach may now be planted in rich warm soil. A sowing of Scarlet Runners for succession may be made, also of French Beans, and a few of the Broad Windsor. Some dwarf Marrow Peas may now be sown, and early ones topped; Spinach for succession may be sown, also a few seeds of *Scorzonera* and *Salsafy*. A few Lettuces and Turnips, if required, may be sown in cool shady places; sowings of Rampion and Corn Salad may also be made. Root-crops, such as Beet, Carrots, Parsnips, and Turnips, should be thinned as they advance in growth. Potatoes should be hoed, and, in some cases, the soil between the rows loosened with a steel fork; a little earth should be drawn to the most forward of them. Ridges for Cucumbers may be prepared, and the ground got ready for Celery.

Epithets of the Months.—The following titles of the months are taken from "Five Hundred Points of Good Husbandrie, newly set forth by Thomas Tusser, Gentleman." London, 1610:—

A kindly good Janiaere
Freezeth pot by the feere.
February fill the dyke
With what thou dost like.
March dust to be sold
Worth ransom of gold.
Sweet April showers
Do spring May flowers.
Cold May and windy
Barn filleth up finely.
Calm weather in June
Corne sets in tune.

No tempest, good July,
Lest Corne look ruely.
Dry August and warme
Doth harvest no harme.
September blow soft
Till fruit be in loft.
October good blast
To blow the hog mast.
November take faile
Let Skep no more faile.
O dirty December
For Christmas remember.

The word *skep*, in Lincolnshire, is in constant use for a peck measure; while in Leicestershire, and elsewhere, it is used indiscriminately for any small wicker-work basket used for packages, the larger forms being called "hampers." In Scotland, beehives are called "skeps."

GARDENERS' COTTAGES.

THE accompanying sketch, which represents the gardener's cottage at Henham Hall, Suffolk, the residence of Earl Stradbroke, may well be taken as a model of how such a necessary appendage to a garden may be made an attraction, instead of an eyesore requiring a screen to hide it from view. Its internal arrangements are quite equal to its external appearance; it has a good entrance hall and spacious staircase, from which ready access may be obtained separately to each room. The four front rooms are about 14 feet square, and the back rooms, kitchen, and other appurtenances, about 12 feet square. The back premises communicate with a private road, a better arrangement than that of making the gardener's cottage form, as is often done, a central object in the kitchen gardens, or range of forcing houses. The garden-front, partly shown in the accompanying illustration, is tastefully laid out in the form of a flower garden enclosed by evergreens, and an ornamental wire-fence clothed with Roses, and the walks leading to the kitchen gardens and pleasure grounds are also spanned by arches, which are covered with climbing plants. The

to afford a pleasing variety of colour; and, by way of experiment, such plants as Camellias, Myrtles, and scented Verbenas, are used in sheltered spots, in which they will stand mild winters without any protection. I may remark, in conclusion, however, that the effect produced by these plants, comparatively common though they are, is, as in all other matters connected with gardening, just in proportion to the care bestowed on them; if they are annually thinned, and the young wood trained in to replace the old and worn out shoots, fine blossoms will repay the operation, but if their pruning consists in simply mutilating them with garden shears, their blooms will grow "small by degrees and beautifully less." J. G.

Weather Predictions.—At a recent meeting of the East Kent Natural History Society, Mr. Kingsford said he agreed with the general impression that the seasons were more subdued as regards cold and heat than formerly; at the same time extremes of temperature from time to time occur. Prognostications of forthcoming weather, he considered only mislead, because not tested by or based on true knowledge and facts. The test of the general condition of

Gardener's Cottage at Henham Hall.

central porch forms a sort of open conservatory, in which, owing to its sheltered position, a gay display of floral beauty is constantly kept up. It is, however, to the increased interest which climbing plants give to buildings, that I wish now specially to refer. Drapery of this kind not only enhances architectural beauty where it exists, but also covers a multitude of defects in buildings of ordinary appearance. I need only refer to trade lists to prove that there is abundance of material in the shape of flowering, foliage, and berry-bearing plants suitable for the purpose, and for producing a fine effect at all seasons. I may add that the most conspicuous plant in bloom at present (May 11th) is the Yellow Banksian Rose, which is quite a cloud of blossom, and which contrasts well with large masses of Forget-me-nots, and other spring flowers at its base. When this Rose goes out of bloom the different varieties of Perpetuals, Teas, and Chinas come into beauty, conspicuous among them being the Climbing Devonensis, which, under the shelter of the overhanging roof, blooms in perfection. To provide for autumn and winter effect, plants of variegated Ivies, Cotonaster, Pyracantha, &c., are trained amongst the Roses so as

the summer by the character of the weather at the vernal equinox had more than once proved correct, but he preferred more scientific methods. The early arrival of birds in autumn was said to foretell a severe winter. Last September a woodcock flew up from the shrubs near his house, but there had followed anything but a hard winter. Similarly, the abundance of Holly-berries, greater than had been previously noticed, did not confirm the adage as regards the season; for neither was the weather severe, nor were there as many redwings and fieldfares, as usual, to feed on the thick crop. His grandfather had recorded that on January 1, 1779, a remarkable storm occurred, long known as the "new year's gale," which blew the roof off his house; yet the following spring was so forward that Gooseberry pudding was eaten in April. The severity of former winters, as well as the presence of birds, not now seen in the same localities, was demonstrated by several incidents. Associated with climatic changes were many alterations in the lands in the neighbourhood of Canterbury. The surface had become drier, the places where water remained for months, yielding an extensive evaporation to the atmosphere, had been greatly reduced. Ditches had been filled, woods cut down, and more land brought into cultivation and drained; these, and other causes, speak for themselves in a meteorological point of view.

GARDENS AND VEGETATION IN THE RIVIERA.

TO THE EDITOR OF "THE GARDEN."

SIR,—I have recently received two letters from a friend travelling in the South of France, principally in the department of the "Alpes Maritimes," which appear to me so interesting that I fancy they may prove equally so to the readers of THE GARDEN. I have selected those passages which I deemed of general interest, placing them under distinct headings, and forward them to you for publication, if you think proper.

H. NOEL HUMPHREYS.

Hereabouts the Alps come down to sun themselves by the southern sea, and Mentone is one of the towns that nestle at their feet, protected by them from the harsh north and east, and it is usually considered the best sheltered spot on the coast. In the gardens the Geraniums seem to grow wild, and flower profusely during winter and spring; the Castor-oil plant lives through the winter; the Wigandia (macrophylla, grown for its huge leaves only in the London parks) becomes a tree 20 feet high, covered with panicles of blue flowers, very handsome; the Mesembryanthemum drapes the walls and rocks, as at Naples; *Salvia gesneræflora* is a bush of fire, in April; the Heliotrope flowers untouched through the winter, as it would against a back wall in a warm greenhouse; the fine old *Sparmannia africana* blooms freely in the open air; and over 200 kinds of Cacti and succulent plants thrive there also. So much for the gardens of the town; gardens, which, however, contain many other things, including the Gum trees talked of so much of late. The main features of the place are the cultivated gardens, nearly all terraced, as you have so often seen in Italy, but covered with a vegetation which one rarely sees there.

Olive Trees.

In Italy the Olive is merely an "orchard tree," and does not seem to be at all happy with its lot. Here, too, it is essentially a cultivated creature; but it grows so big, stately, and venerable-looking, that it has little trouble in deceiving one as to its real position in the world. One sometimes forgets the prim narrow terraces, and the world of care bestowed on its culture, and groups it with the old park Oaks and Kensington Elms, and other tree patriarchs. It has grace too, for it often weeps like the Willow, and, however old the trunk or branches may seem, the shoots are always fresh and vigorous, as if on seedling trees. It never knows when to die! They say some of the trees hereabouts may have afforded oil in the time of Augustus; and they certainly look as old as any trees I have ever seen. Sometimes you see a tree split up into three or more stems, as if he had been on the point of death from old age 500 years or so ago, but was saved by several young strips of living bark running down his time-worn hide. These said to themselves we must not let the old one die; and, by each doing his best, they have managed to keep a little of him together near the ground yet. Sometimes the trees are pierced with holes, as if they had in old times stood a siege; but they tell me that in olden times it was thought a good practice to bore holes into the trees to make them fertile. These holes you must have frequently seen in your long Italian journeyings. When the branch of an aged tree here seems at all overlaid or weak, it is propped carefully up—as a good old man might be—on a crutch. Some trees spread wide about the root, so as to remind one of an old Chestnut. It is impossible to give any idea of the variety and beauty of form possessed by the Olives here; but, as I have not seen them either in flower or fruit, as yet, I have perhaps said enough of them for the present.

Lemons and Oranges.

After Olives, Lemons—the staple crop of the land. A shade or two warmer, and better sheltered than many of the shores of this sea, the Lemon is at home. Madame Lemon is a little more delicate in constitution than Monsieur Orange, and, as she is the more valued here, he mostly goes to the wall. Everywhere you see the Lemon groves, which are flowering and fruiting at all seasons, and form a most valuable property even on a small piece of ground. The Oranges are grown, particularly the bitter variety, but not nearly so much as the Lemon. They, however, can be grown over a much

greater area of Southern Europe, and are therefore not so profitable as the Lemon. What is this fair star-like white flower, in such profusion beneath the Oranges and Lemons? The Naples Allium, pretty as any Daffodil, and as bright a spring flower as you would wish to paint. I intend to bring home a thousand bulbs of it; and, should you make a wild-garden, I will ask you to scatter some of them in it. It is so plentiful in the Lemon groves, that the ground is whitened by the blossoms, which appear about the time those of the Anemones are passing away.

Indigenous Vegetation.

There is a little cape Francewards, and just outside of the town, not altogether occupied by Olives, and here one gets some idea of the native vegetation of the place. Here, too, one gets out of the odour of the Lemon groves and feels the cool breath of the sea. And what a sea! You know its divine blue well; but nobody, I suppose, has ever attempted to paint, or even remember in any distinct way, the many different tints that one sees in it; near a muddy or sandy beach it seems but a northern wave that is washing the shore; but here, on the brow of this cape, where there is no shingle or loose material, a very different aspect is presented. The worn rocks spring from the deep blue water, and, as the waves roll high against them, the crest of each, as it rears over, is exactly of the same peculiar green hue as the crest of Niagara, when the light from below first strikes the falling mass. It is on stormy showery days that the tints of this sea seem the most varied and charming. The vegetation is peculiarly interesting, as a good many of the native plants are among the oldest and most favoured plants of northern gardens. The low copse vegetation beneath the Aleppo Pines is composed almost exclusively of Myrtle and Rosemary; the last in flower in April, and showing here and there a white variety. The Rosemary is seen everywhere. In such company, one would naturally expect to meet Miss Lavender; and here she is, happy enough on the warm rocks. The Lavender is so abundant on the sunny mountains all round here, that there is no need to cultivate it for distilling, so the stills are brought on to the mountains when the flowers are ready. As interesting in their way as any of the preceding, are the little bushes of the true garden Thyme, which everywhere dot the land. It is exactly the plant cultivated for ages as a pot-herb, and, of course, quite different from our common field Thyme. Then we have the Rue, common enough; as if so many fragrant herbs could not be permitted to grow together in peace without an emissary from the evil one, in the shape of the foetid Ruta. If we pass from this cape to the hills around the town, many interesting plants are met with, as, for example, an Acis, which flowers in spring, and is like a Snow-drop; beautiful insect-like Ophrys; Hepaticas, here and there mixed with our common Primrose; and, most beautiful of all, perhaps, the graceful and handsome Dog's-tooth Violet, with its mottled leaves. Daffodils and Anemones have been very numerous, but in April they are seen less frequently, and many of the rarest flowers select the winter as their blooming time.

A Valley in the Maritime Alps.

If we pass up one of the valleys for some distance, a better idea of the region generally may be obtained, and there is no more interesting one than that which runs up to the Col de Tende, three hours' walk or so above Tende—the Tende of Beatrice, of whose history you know. We enter the valley through miles of conglomerate cliffs, often several hundred feet high, and here and there veined with sandstone, which is fretted into tracery, looking almost like that of a decaying gothic cathedral. Few things among the rocks look more imposing than these cliffs, made up of blocks and stones and pebbles, from the ruins of some old world. Imagine the torrents, and the rivers, and the continent they must have seen into to admit of such a cyclopean deposit! The culture of the Olive by no means ceases with the sea slopes, but runs very far into the warm valleys, the slopes of which are terraced for its reception. There is one place in this valley where the hills assume the form of an amphitheatre, and the terraces and Olives follow the same outline. This is a peculiarly interesting sight, and one you would like to sketch. It looks like the Coliseum escaped to the woods, and enlarged a

hundredfold. Hard by, and nestled in the grey wood, is one of those close built Italian towns, so attractive to the artist (and to the general eye, at a distance of some hundred yards or more), but which are so dismal when you walk through them; the streets like deep graves; the houses so miserable-looking, externally; the filth inside so evident, that one begins to be grateful for having first seen the light in a clean, if not a picturesque house. Some of the streets are so narrow that you might hand articles from one house to another from the windows! And into these towns the people crowd, instead of building in their pretty Olive gardens. It is part of the curse of the old time that is upon them. I suppose they crowded up for defence, and now, when both castle and ramparts are gone, they crowd still. They look all the worse for it, too, and have the faces of creatures born in the stews of some unhealthy city. As we pass along the outer street, a great snake-like stem of a Vine is seen emerging from a hole in the wall of the lower storey, and gradually winding its way to the top, where it forms (trained on a trellis over the flat roof) the upper story, so to say. This is but one of the countless ways of training the Vine in Italy. What a docile plant it is for the trainer! and what curtains it makes at Naples, stretching in lines, four deep, from tree to tree! And what covered walks at Florence! But I must not begin. A man with one-half of your knowledge of Italy might form a charming illustrated volume on the "Vine in Italy." What a contrast to the primmer than Currant-bush Vines in France! But taste the *vin du pays* in these valleys, and, ten to one if you do not imagine that the fiend of astringency has possessed you at last. Happily, however, the inns mostly have some fair Asti, and Asti, when good, seems to me (a poor judge) the most agreeable wine of Italy.

Terraces.

When the terracing for the Olives on the low grounds and hill-sides is completed, next come terraces for Wheat and Vines. It is surprising to see how these terraces are won from the mountains. You look above the Olives and against the face of a mountain that seems too steep for any climber but the chamois, and are astonished to see little horizontal lines, which prove to be terraces. Man, the featherless biped, has been there, and, wherever it was possible, stolen a few yards of earth from the stony face of the scarp. Some of these terraces are not more than a few yards long and 4 or 5 feet wide. Talk of difficulties of culture after this! In more accessible places than this, one can see the terraces with their green young Wheat, which, I am told, they bear, year after year, without end and without change. After the Wheat frequently comes a crop of Indian Corn, which the climate is so good as to perfect, even though sown after the Wheat is cut. In some of the small fields, and most easily accessible terraces, we saw the old Roman plough—the Virgilian plough—at work; and not a bad implement, though a very rude one. I presume this was the first of the great series of English ploughs also; as, of course, the Romans would have introduced it. They could not rule and civilise us for nearly 500 years without using the plough as well as the sword. There seems a great scarcity of animal life in these valleys—even the dogs are few, happily. Some few teeth and a tuft of black wool on a high ridge, however, remind us that the wolf is yet seeking what he may devour on the hills, for these are all he has left of a sheep. He is, however, far from common, only leaving the high woods when driven by the heavy snows to seek food lower down.

The red Valerian grows well everywhere in the Riviera Valleys. So, by the way, do some of our favourite garden shrubs, as, for example, the beautiful Venetian Sumach (*Rhus Cotinus*) which is a true rock shrub, dotted over the enormous precipitous walls of stone everywhere. So, too, in these valleys we find the Oleander—which we usually associate with the Jordan. It grows in the river-beds and banks, and freely in the warmer and lower parts of the valleys. In these valleys, like many others, the rocks frequently become almost perpendicular, and this by no means only when the great face is formed of one solid mass! Many of the masses of stone are free, having just a resting place on the mighty wall. Hence, after heavy rains and similar causes, ponderous slices slide down into the valley or on to the mountain road, leaving such a ruin

as makes one grateful to have been out of the way when it tumbled down. Well, for many miles throughout this valley one sees these colossal walls of rock, and they interest us mainly from the vegetation that clings to them. Wherever a chink occurs, or a resting place of any kind, there is the home of a mountain shrub, so that no matter how high the rocks are, they are garnished everywhere, sparsely, with the young green of spring or the silvery tints of its bush flowers. Most frequent, perhaps, is the common European Amelanchier, which forms a low-spreading bush, with white flowers, very ornamental as it dots the cliffs 400 feet overhead. With it, and a little prettier, and also with white flowers, is the Mahaleb Cherry, a species very much used by the French for grafting purposes—I mean as a stock. Here and there, among these whitened bushes, is a stain of glistening green, that of our old friend, the Ivy—native here, of course. Sometimes the eye is refreshed with a mass of the most delicious, fresh, and tender green; it is that of the Lime tree, which, on a ledge larger than usual, has attained, after many years of effort, a height of 10 feet. It looks all the more striking from contrast with the dark green Cypress bushes near, and with the dark green Pines above. The Arbutus may be seen on the warmer slopes, not at great elevations; its fruit is very good here in autumn. Here, too, is a rather uncommon tree, the *Celtis australis*, small and bush-like, but forming a noble tree in good ground in shrubberies. Pretty among all these is the yellow Coronilla Emerus, which suspends its strings of coronas from every rock. The ground is carpeted, in the higher parts of the valley, by the curious little Cob-web House Leek (*Sempervivum arachnoideum*), and the fine strap-leaved silvery Saxifrage (*S. ligulata*) is abundant in large tufts. But what are these delicate stains of lilac among the Grass on that high bluff? The flowers of the charming Margined Primrose (*P. marginata*); you know, the little Primrose with a vein of silver round the margin of the leaf. This is abundant here, and frequently spreads so as to form almost a tuft. There are two other good Primroses here, *P. latifolia*, which I saw very few plants of, a rare kind, and Allioni's Primrose—a beautiful dwarf kind, with fine rose-coloured flowers. This was in abundance, staining the face of an enormous cliff of solid rock, several hundred feet high. The roots had wormed themselves into the smallest chinks, and there formed tufts of little rosettes, every one of which bears a brilliant flower, almost large enough to obscure the plant that bore it. Except for a few yards at the base the plants are wholly inaccessible to man, so that *P. Allioni* will, probably, have its garden there for as long as the rocks will endure. I forget if I told you before that our common Harebell is replaced in these regions by a species with somewhat larger flowers, and very ornamental, *C. macrorrhiza*. The Maiden-hair Fern abounds, as you might suppose; sometimes, as one goes down to drink at some stream—the streams that come into the main valley from the gorges, are usually clear as crystal—one sees the worn walls carpeted with the Maiden-hair Fern. Frequently it creeps into caves, and mantles them too, hanging down freely from the roof. A striking contrast occurs between the arid-looking mountains and the water-meadows in the valleys, through which tiny streams wind, and from which several crops of Grass are annually obtained. Between these meadows and the rocks on stoney flanks, for the most part, the common Chestnut is abundantly cultivated; the Chestnuts from this valley having a great reputation. This is probably owing to the trees being pruned, and in an excellent manner. They are not mutilated, but the branches are simply thinned, and this, of course, throws the vigour into the remaining ones. This is a lesson in its way, as, obviously, if the Chestnut is greatly improved by this process, it is no less needful for every other kind of fruit. The Chestnut is peculiarly valuable here, as it grows on arid-looking slopes where the Pear and Apple would, I fear, have no chance. The Mulberry is common, and so is the Fig, which latter attains stately dimensions in the lower part of the valleys. I measured one since I wrote last, 2 feet 6 inches in diameter of stem, and 60 feet in diameter of branches—a very noble object. What a paradise it must be in autumn for those who love green Figs, if the Figs happen to be of good kinds! The Walnut is also common, and profitable.

I should like to have a walk with you through one of these valleys, but then you would want to sit down and sketch at every step. I will now bid you good bye for the nonce, by the fringe of the receding snow on the Col de Tende, where a few blossoms of the small white form of the spring Crocus, are opening their deep cups to the sun.

THE FLOWER GARDEN.

SELECTIONS OF ROSES FOR VARIOUS PURPOSES.

THERE is a difficulty in making selections of Roses even for special purposes, because so many gardens have their peculiarities of soil and climate which require to be taken into account, in order that the best possible selection may be made. With those who are not well acquainted with Roses and the conditions of their successful cultivation, it is the best plan to appeal to some one who is well informed on the subject. By this means the end desiderated may be surely and completely attained. The following lists, then, should be taken as of a general character, as the best only for such gardens—which are numerous—where no special conditions of soil and climate exist.

100 Good Show Roses.

Anemone Robinsonii.—As there is no answer in last week's GARDEN to the inquiry (see page 372) about this Anemone, I may mention that I got my original plant of it from the Manse Garden of Kirkpatrick-Juxta, Dumfriesshire, some eleven or twelve years ago. The Rev. Mr. Little, the late incumbent, was an excellent botanist,

and he considered it merely a seedling of the *A. nemorosa*, which overran his borders, and he allowed me to take the only little patch I could find of it. In our prepared spring border it grows stronger and larger than it did in the border and walk about the Manse door. I have given it away to many friends, always under the name of "Mr. Little's Anemone," and I saw it first at the Botanical Garden here, named *A. Robinsonii*.—F. J. HOPE, *Wardie Lodge, Edinburgh*.

THE TRUE MEDICINAL RHUBARB.

(RHEUM OFFICINALE.)

UNTIL quite recently, the species of *Rheum* yielding the best medicinal Rhubarb has never been seen in our gardens, owing, probably, to the fact that a great part of the district where the plants grow has not, as yet, been explored by travellers. What is known in English commerce as the best 'Turkey Rhubarb' in reality comes from China, through Russia, by way of Kiachta. It was formerly imported from Natolia, whence the name Turkey Rhubarb. The root is said by Pallus to be dug up in the summer, washed, bored with a hole, strung on a thread, and dried in the sun. In this state it is sent to the chief towns of China, and to the Russian frontier town, Kiachta; at the latter place it undergoes careful examination by the agents of the Russian Government, and all inferior or decayed specimens are rejected. In 1867, what is now regarded as the medicinal Rhubarb, was introduced into French gardens, and has more recently, we believe, been added to the Kew collection of medicinal plants. At p. 206 for the present year, we gave an account of the plant; and we are now enabled to give an illustration of it. This Rhubarb, as will be seen, is a plant of noble aspect; and, although, perhaps, not sufficiently hardy to withstand severe spring frosts, it will, doubtless, form an attractive decorative plant, either on lawns singly, or in other prominent positions, during the hottest months of the year.

WINTER STOCKS.

WINTER Stocks comprise the finest and most effective of this charming family of sweet-scented flowers—not that they possess brighter or richer hues than the summer or annual kinds; but their biennial growth admits of a much larger development of the flowers, and to this is generally allied a free-branching habit combined with a long blooming period. Winter Stocks comprise the Brompton, Queen, Winter Cape, and Intermediate kinds; but these latter cannot, in any case, be regarded as hardy, and scarcely deserve this classification. The true Giant Brompton is the finest of all the Stocks; as, where it is well grown, it oftentimes rises to a height of 2 feet, and then throws up magnificent spikes of bloom 12 inches in length. When grown in this way, the Brompton is a grand border-plant, and is well worthy a place in the finest garden. There are three colours in the Brompton—scarlet, white, and purple; and there is an inferior strain of the Brompton, as distinguished from the Giant, that is more branching, and but rarely develops double flowers. Of these I have grown all three colours; but have found them so inferior, that they have been discarded. Of the Giant kinds, I grow both the scarlet and white; but I have not, nor have I, indeed, ever, seen the purple. No doubt it exists somewhere; but it

is certainly rare. The scarlet is well known; but it is more commonly found amongst cottage gardens than in those of greater pretensions. It is said that all single flowers that have, say, five or six petals, will assuredly produce pods that will contain seed of double kinds. This may be partially true, as regards a good double strain; but that it is not absolutely true of ordinary strains, I have had abundant proof, having, on several occasions saved and raised the seed from such flowers, but the result was that they all came single. Where a good strain exists it is best to pinch out the points of all flowering shoots after they have developed a fair number of blooms; and then, as the seed swells and ripens, there is more strength and plumpness in it than would be found if the plants were allowed to seed indiscriminately. The true Giant White Brompton is a magnificent Stock, producing enormous spikes of huge double flowers. I obtained this kind after considerable trouble, and I have now a fine lot of it in bloom. The Winter Cape Stocks are little known, and form quite a distinctive class, as they are intermediate between the Brompton and the Queen, having the tall stems of the one with the bushy heads of the other.

They are, however, not so hardy as the latter; although they would do well in sheltered gardens, where they would make delightful borderplants in spring. Of these I have five colours—white, scarlet, purple, lavender, and fawn; the two latter shades being exceedingly pleasing, and are not to be found in any other winter kinds. I find that these give about two-thirds double to one of single; the Bromptons, if of a good strain, giving about one-half of each. The Queen Stock forms one of the oldest and most useful of all winter kinds, and it is, I believe, the hardiest. Here, again, the three common colours of scarlet, white, and purple only are found, except where, in some cases, variegated flowers come, a circumstance probably arising from the fact that the white and scarlet, or the white and purple, have been grown in close juxtaposition. As I pass to and from here to the Feltham railway-station I pass several cottages, the front gardens of which are almost full of scarlet and purple forms of Queen Stocks, dwarf, branching, and literally a mass of beautiful flowers, of these more than one-half are double, and the strains pure and good. These Queens

Rheum officinale.

seem to be almost stemless as their heads rest close to the ground and their branches of flower rise to a height of from 10 to 12 inches. The white kind of Queen Stock is not common, although I have seen it in years past, and, no doubt, some of the readers of THE GARDEN are acquainted with its whereabouts. The Queens are largely grown in market gardens, and their flowers are cut for market purposes; they are of equal value for decorating the borders of private gardens. Intermediate Stocks are, necessarily, Winter Stocks, but by no means hardy. If seed of them be sown early in spring under glass, it is probable that the plants will only just come into full perfection in the autumn, too late to be useful. Seed of these should be sown during the months of July and August, but the first week in August is very suitable if sown under glass. The plants should be pricked out in a cold frame, or be potted up and placed in a frame or cold house to stand the winter, and then, if so desired, should be turned out into the open borders or beds about the middle of April, when they will bloom freely for several weeks. The Intermediates give still white, scarlet, and purple, and, if of a good strain, will yield

about 80 per cent. double. I should much like to see growing at Chiswick a collection of every known variety of Stock, it would be a most interesting sight and as sweet as beautiful.

Bedfont.

A. D.

LILY OF THE VALLEY.

THE flowery month of May produces no plant more exquisite either in form or fragrance than this. Most plants have an especial beauty of their own—a something distinctive that is capable of endearing them to us; but this Lily has attractions peculiarly its own. The graceful manner in which its pretty white bells hang on the slender, arching stems, and the agreeable contrast which they make with the bright green foliage, have rendered this little flower not only a favourite with all parties, but especially so with our poets. This little modest flower formerly grew in our woods and valleys in great abundance; but increased cultivation has rendered it comparatively rare in a natural state. In gardens, however, it is the most cherished of all hardy flowers, and the quantities of it used for forcing in early spring would surprise the uninitiated in these matters. Old writers on gardening tell us that about the end of the fifteenth century it grew abundantly on Hampstead Heath, in Bushy Park, at Lee, in Essex, and, indeed, in most counties in England. It grows plentifully in the woods of France and Germany, and is indigenous to most parts of Europe—from Italy to Lapland. It is sometimes called May Flower; but as it grows spontaneously in shady places, though not in reality a Lily, the name Lily of the Valley seems a natural one. The best situation in which to place this Lily in the garden is where it will be partially shaded by shrubs and trees, and it flowers even better in a north aspect than when fully exposed to the noonday sun. It will succeed in almost any kind of soil; but it blossoms in greatest abundance in a light soil, rather poor than otherwise; for, when planted in rich garden earth, the roots spread, and multiply rapidly, but the plants produce but few flowers, and, like many other creeping-rooted plants it seldom seeds. This Lily may be planted with advantage by the sides of water, where, beneath the branches of some Weeping Willow, or other pendulous tree, its fragrance quite scents the air. Autumn is the best time for placing the roots of this Lily in the ground, in which they should be covered about 2 inches in depth, and should not be disturbed oftener than every third or fourth year, as they seldom flower strongly or plentifully the year after being removed. When above ground they will require no other attention than that of keeping them free from weeds. Lily of the Valley is said to be so abundant in woods in Hanover that the ground in many places is completely carpeted with it, and the air to a considerable distance scented with its agreeable perfume. In Germany it used to be common to make a wine of the flowers, by drying them in the summer, and in the time of vintage mixing them with Grapes when pressed. A snuff has also been sometimes made of the dried flowers and of the leaves and essential oil of Marjoram. The fresh blossoms, gathered while wet with the morning dew, have also been used for purposes of distillation.

J. M.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Double Cuckoo Flower (*Cardamine pratensis*).—While travelling near Boston, the other day, I met with a double-flowering variety of this plant, growing near a clump of the single kind, which it far surpassed in beauty, and was about 6 inches taller. Is a double-flowered Cuckoo flower a rarity or not?—A. B., *Steaforth*. [By no means a rarity.—Ed.]

***Androsace coronopifolia*.**—This elegant species, with its beautiful diffuse umbels of snow-white flowers is flowering beautifully with me this season. I find it best to treat it as a biennial; it seeds freely. Plants raised from seeds in early spring, and wintered in a cold frame, flower well the following season.—J. W. MORLEY.

***Cheiranthus ochroleucus*.**—Plants of this useful hardy perennial, divided and planted out in July last, are now masses of bloom, about as much in diameter as in height (6 to 8 inches). Being deliciously sweet-scented, this showy little Wallflower deserves even more extensive cultivation than it at present receives.—WM. RUMSEY, *Joyning's Nursery, Waltham Cross*.

The Stemless Gentian (*Gentiana acaulis*).—Gentians of various varieties are generally supposed to follow pretty closely the thaw lines on mountains. As the snow melts, the azure blue springs forth behind it, and no severity of weather seems to hurt the Gentians. The best I have ever seen were in Perthshire, on a cold clay bottom and a northern aspect. Yet I have never seen Gentians in East Anglia so full of flower as now. The plants are all flower, and their flowers are large and fine, and the plants healthy, as if they had rather enjoyed, and thriven the better for, the mildness of the winter.—D. T. F.

St. Bruno's Lily (*Anthericum (Czakia) Liliastrum*).—When in bloom, this is one of the most charming of all spring-flowering plants, either for a warm sheltered border, or for pot-culture. I recently saw some pretty little specimens of it blooming in a cold pit in Messrs. Barr & Sugden's trial ground at Tooting, and it struck me that it ought to be more generally grown, as a decorative plant, than it is. It has narrow glaucous foliage, and erect spikes of pearly-white blossoms, deliciously scented. If planted out, select a warm moist border in a sheltered position for it, as its delicate blossoms are often injured by dry cutting winds.—B.

THE FRUIT GARDEN.

WATERING PINES.

IN reply to Mr. Simpson's strictures on my remarks on this subject (see p. 426), I beg to say that what I have advocated, and further wish to confirm, was sufficient, but not excessive, watering. I did not, nor have I any cause to describe, any disastrous results attending this practice; but it is abundant watering, or watering of any kind, after the fruit commences to ripen, and the baneful consequences which I have found to follow, that I particularly wish to guard against. That many Pines are over watered cannot be controverted. Fruits of all kinds, Pines not excepted, that are ripened and gathered from plants that are living in a semi-aquatic state, are always very much inferior in flavour to those ripened under more genial conditions. Pines so ripened may be exceedingly rich and flowing in juice, but where is that peculiar saccharine flavour, so desirable in the Pine, and without which it is of little value? I have not the schedule of the Nottingham show by me, but I presume the society must have been more liberal in those days than it is now, if six or eight Queen Pines were awarded first and second prizes individually. Here again the finely swelled and finished appearance is all that is looked at. Unfortunately, Pines are never tasted on such occasions. Good prizes were awarded to Pines at the Glasgow International Show in 1872, and those who obtained them are, of course, at liberty to make the most of them now, but the editor of the *Gardener* (whose opinion on anything connected with Pine culture is worthy of the highest respect), in his notice of the exhibition in question, sagaciously observed—"We have omitted remarking on the Pines exhibited at this show, for they were very ordinary, and some of them were all but rotten, and should never have been staged." As I am not in the habit of frequenting any of the local shows which Mr. Simpson mentions, I have never inspected his fruit on such occasions; but, if those which he exhibited last year at the International Show in Manchester were samples of his wet practice, I would recommend him to give the comparatively dry system a trial. I am asked if I know under what conditions the Pine grows and fruits in its native habit? I have always given more attention to its artificial cultivation at home than abroad; but, so far as that is concerned, I suppose that Mr. Simpson's knowledge and my own are derived from much the same source. A friend of mine, a planter in the tropics, who is rather fond of a good Pine, in a recent letter, says—"Pine-apples grow naturally here; they are as finely flavoured as English grown Pines during the dry seasons; but, if not protected during wet seasons, they are not worth eating." Can any but one inference be drawn from this? I have for weeks and months watered every stove plant under my charge daily, and Mr. Simpson (see p. 217) says, "The Pine requires as much water as any ordinary stove-plant; and, unless it gets it, it will not thrive." The inference, therefore, is that it should receive water every day. After some comments on air-giving, watering, and many figures of temperature to be strictly adhered to, we are informed that "with plenty of water at the root a Pine will thrive luxuriantly without shutting up or syringing at all." The technical definition of "shutting up," as applied to Pine growing, is the closing of the ventilators to exclude cold air. Surely, therefore, there must be some mistake in reference to this statement.

J. MUIR.

WIRING GARDEN WALLS.

TWENTY-TWO years ago I had two Peach-houses erected under my direction; they were lean-to houses, the length of which was about 120 feet, and the trees were to occupy the back wall, which I had wired pretty much in the way in which walls are now wired. When building the walls I had square plugs of wood placed in them at certain distances apart; to these upright laths were nailed, at distances of 5 feet. Between the laths the wall was plastered, and the laths were embedded in the plaster to a depth of nearly an inch, leaving no interstices in which vermin could find a shelter. After the plastering was finished and the projecting portion of the laths painted, the wires were stretched along the wall at distances of

5 inches apart, each wire was firmly secured to the upright lath by a staple after the wire had been tightened to its greatest tension by a screw and nut. The Peach trees planted against this wall were under my care for sixteen years, and during the whole of that time I cannot remember that any harm was done to the young shoots by tying them to the wires; but the system which I followed may, in part, account for this; they were pruned on the spur system, the young leading shoots I never tied to the wires until they had grown a considerable length, and even then I began at the base of the shoot, proceeding with the operation at stated intervals, as the shoots had acquired hardness and consistency sufficient to bear the pressure of the ties. In tying I wound the matting once round the wire, tied it in a single knot on the side next the wall, and then brought it round to the front; by this means the shoot had room to develop itself, besides having protection from direct pressure upon the wire. Whatever, therefore, may be the faults of wire trellises out-of-doors, I consider them a great advantage where Peaches are grown upon walls under glass. I have here only two small Peach-houses, the trees in which are grown in a similar way to those I have just described. Every year the trees are taken entirely off the wires and the back wall is white-washed. After the trees have been carefully painted with a suitable composition, they are re-tied to the trellises ready for spring work. I have never had an opportunity of trying a wire trellis on walls out-of-doors.

J. T.

FRUIT SHEDS.

A YEAR or two ago I gave an account of an open glazed shed built by Mr. Foster, of Beeston, accompanied by an illustration and description. It is five years since it was planted, and it has every year had a fine crop of fruit. This season it is worth going a long way to see. In my experience I have seen nothing in fruit culture so remarkable as the uniform success of this fruit shed. Who would have thought that a shed open to the north-east would have produced crops five years in succession as this has done, in spite of unfavourable seasons? Last year, when no one here had Apricots, Mr. Foster gathered twenty-five dozen beautiful fruit from two trees which had been loaded every year since they were planted. One Plum—a Rivers' Prolific—produced, when it was cleared, thirty-five pounds, and it was estimated that ten pounds had been previously gathered. A Pitmaston Orange Nectarine bore twelve dozen beautiful fruits, and now every tree in the shed is as full of fruit as it is possible for it to be. When it is added that these trees have never been watered since they were first planted, that they have never been syringed at all, and that the only trouble taken with them has been to train them to the wires, thin, and gather the fruit, I think few will deny that the success of this plan of growing fruit is very remarkable. Whoever before heard of a plan of growing fruit under glass when a week or a month's absence of the gardener made no difference, when a frost of 14°, when the trees were in flower—as we had when Apricots were in bloom—did not require to be guarded against, and did no harm? No wonder people are building similar sheds all over the country; for, one thing is quite certain, that no plan of growing unforced fruit has ever been tried to be at all compared with this, either for certainty or economy. Nobody, after seeing this shed, would for a moment think of building a shed for pots and soil, and covering it with slates or tiles instead of glass.

Chilwell.

J. R. PEARSON.

Wood instead of Fruit in Gooseberry Bushes.—How is it that our Gooseberry bushes are throwing out quantities of young wood and not bearing fruit? They were pruned as usual in the autumn and manured; in early spring they showed good promise of fruit, and blossomed at each joint along the stem, but now, instead of fruit, a young shoot about 3 inches long has appeared, besides the young wood which always comes in the centre of the tree, and any fruit that was formed is falling off. This is the case with young as well as old trees. They are planted along the borders of a fruit and vegetable garden, and are manured every year.—A CONSTANT SUBSCRIBER, Belfast. [The bushes in question have, probably, been too close pruned in the autumn, and by being very vigorous from growing in a richly-manured border, that would cause them to make a

quantity of young wood instead of setting fruit. If this is the cause the evil may be cured by root-pruning, or by lifting the bushes and replanting them in the autumn, if not too large and old. No pruning the young wood should be done till the spring of the year after being planted, and then only by thinning out a few of the branches where too thickly placed, and especially all in the heart of the bush. I never prune or spur the young wood of my Gooseberry bushes; all I do is thin out the branches in the spring, before the buds break, and thus they never suffer from the birds eating the fruit-buds in severe winters, or from their making too many shoots to the detriment of the fruit.—WILLIAM TILLERY.]

Gooseberry Caterpillars.—I have seen acres of Gooseberry trees in market gardens stripped of foliage by caterpillar, a cure for the ravages of which may be found in a decoction of Foxglove. Get a quantity of stalks and leaves of this plant, bruise them, and throw them into a copper of boiling water, and let them simmer all night. The next morning the liquor will be the colour of porter; this strength can be reduced by adding water. Strain through muslin or fine netting, and syringe with a very fine rose, if possible, letting the liquid fall on the trees like dew. If no copper is handy, use a water-barrow; pour scalding water on the Foxglove, and cover up with sacks or mats. We have used the above, more or less, for the last twenty-four years, and have always found it to answer. Some recommend Hellebore powder; this I have never tried.—WILLIAM HILL, Keele Hall, Staffordshire.

Codling Moth and Sheep.—We have repeatedly urged for years past the importance of turning flocks of sheep and pigs into orchards at the time the young and wormy fruit is dropping. These animals will get at least a part of them. One of the most successful experimenters in this way is Mr. Harris, of Rochester, who gives some striking proofs of the advantages of the practice. He holds the codling moth in check in one orchard by pasturing it with sheep. Another orchard, forty years old, has always been used as a hog pasture, and the Apples are entirely free from the codling moth. Outside the orchard in which the sheep run, is a row of seven trees, which produced last year from two to five barrels of Apples per tree, and being unprotected by animals from the codling moth, all the good Apples from these seven trees were put into one barrel. In his garden, where the animals cannot run, from fifty sorts of dwarf Apples there is scarcely a fair specimen.—Cultivator.

The Alpine Strawberry.—In many places Alpine Strawberries are not in much demand before the bulk of the large varieties has been consumed; therefore, as it is not necessary for them to bear till August, it will be better (to avoid exhaustion by unnecessary cropping) to go over them now, and, as far as possible, to cut off all the flowers. Where only a few are grown, this may easily be accomplished with the knife; but, where they are grown in quantity, this would be found a tedious process, involving a good deal of labour and time. We, therefore, use a sharp scythe. Any man accustomed to the handling of such a tool would run over the beds in a few minutes, skimming off the flowers; and, if a few leaves are sacrificed, it is comparatively of little importance, as the plants make foliage so rapidly at this season. This, also, would be a good opportunity to mulch them, if not already sufficiently done. Half-decayed stable manure we find to be the most suitable material for mulching Alpines, as it furnishes a good deal of support and stimulates production. It will settle down and form a clean surface long before the fruit is ripe, and the fruit of the Alpine is supported more by dense close foliage than other Strawberries.—E. HOBDAV.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Golden Queen Grape.—Can you kindly give me any information respecting this Grape.—DELTA. [It is a seedling between Ferdinand de Lesseps and Black Alicante. The bunch and berry are exactly like those of the Madresfield Court, but in colour bright yellow. The flavour is said to be excellent.—ED.]

Singular Lemon.—Prof. Oudemans has recently narrated a case in the *Archives Néerlandaises*, in which a Lemon, when cut across was found to partake internally of the characters of both the Lemon and the Orange, four of the segments having the colour and taste of the Lemon, the remaining five those of the Orange. The exterior was in nowise different from an ordinary Lemon. M. Oudemans inclines to the view that this fruit resulted from the fertilisation of the flower of a Lemon by the pollen of an Orange.

Attempts to Protect Vines from Frost.—During the recent severe and most destructive frosts, every possible attempt was made in France to protect the Vines by means of straw coverings, made up into the shape of beehives, umbrellas, &c., and in many places wooden planks have been used; but these devices have been attended with but little success. Artificial clouds of smoke from fires kindled in the Vineyards have also been had recourse to, but have equally failed; and the only shelter that has at all succeeded, has been linen cloth spread out over the Vines. Surely these facts are enough to convince Vine growers in these regions that cheap canvas, or similar covering, is what is wanted to prevent wholesale destruction.

DRUMMOND CASTLE GARDENS.

By NOEL HUMPHREYS.

ALTHOUGH Drummond Castle is not remarkable either for site, magnitude, or architecture, and although the park is not of great extent, the gardens have become more celebrated than any others in Scotland, and, owing to their interesting character and beauty, have cast a reflected light, as it were, of celebrity on the somewhat inconspicuous building. The charms of horticulture have, in fact, rescued the place from obscurity. Drummond Castle only consists of an ancient keep, still perfect, but now tenanted merely by a fine collection of Scottish weapons and defensive armour, and a fine series of family pictures, many of which are of historical interest. The modern residence is on the same level as the old castle, but is of very recent date. The castle, like most of the strongholds of the period, was naturally placed on the highest point to be found in the domain. The side of the small but elevated piece of high table-land, beneath which the present noble gardens lie, was originally, no doubt, a precipitous and inaccessible rock, the practicable approach to the keep being at the back. In early times the only garden was, doubtless, such a one as could be planned within the battlements surrounding the crest of the rocky hill, in which narrow space the *Chatelaine* had, probably, her bower and her Rose bush, and a few old-world flowers, such as we see represented in the painted miniatures of mediæval chronicles. But in later and less lawless times, when it became possible for a lady to pass outside her castle gates without a company of men-at-arms, the present gardens were gradually formed, which, as a specimen of the geometrical style, are, on the whole, more attractive than any with which I am acquainted—principally on account of the richness and abundance of the foliage which surrounds them; and which occasionally breaks up with such graceful interruptions the lines and devices of the ground-plan, which, without this softening, would have been somewhat glaring and obtrusive. The approach to the castle hill, through the park, is beneath an avenue of Beeches nearly a mile-and-a-half in length, yet not at all monotonous, on account of the many picturesque variations of aspect which occur during the approach, in consequence of the natural irregularities and rocky character of the ground. In many places the road has been cut through solid rock, and these cuttings have become entirely clothed with Mosses and Lichens of olive, grey, orange, and creamy tints, forming a soft velvet mantle of many colours, and producing a most charming effect. In some places the irregularities of surface are of sufficient dimensions to give to the general effect an air of considerable grandeur. It is, in fact, a half wilderness of mountain-like aspect, often becoming solemnly impressive by the continuous shadow of the great Beeches, between the ancient trunks of which sparkling glimpses are obtained of a picturesque lake. The final ascent to the castle is bright and open, and the entrance is through the ancient gateway of the “keep.” By a narrow-vaulted passage the visitor enters a spacious court, on the opposite side of which are the more modern buildings which form the present residence. At the time of my visit the banner of the Drummonds was flying, denoting that “the family” were at home; yet no restrictions on the free circulation of visitors was the consequence. After visiting the interesting collections of arms and pictures in the ancient chambers of the keep, the principle object of a garden-lover’s visit began to be realised by a glorious view over the wide-spread display of foliage, flowers, walks, and fountains, obtained from the parapets of the castle court, which, though not so extensive as that from the top of the old tower, was more rich and beautiful, the objects seeming to be more pictorially grouped and blended than in the bird’s-eye view from the greater elevation. It put me somewhat in mind of Fontainebleau, but it is certainly finer. The main lines of the design are those of the cross of the patron saint of Scotland (St. Andrew), namely, two bands crossing each other diagonally in the centre. Beyond these characteristically national main lines there are, at each end of the design, two broad walks running past the end of the cross, with a circle between them; and beyond is another walk in the same direction. From this main and simple nucleus of the plan scores of minor ramifica-

tions spring, spreading themselves in every direction, and creating, by their intersections, geometric figures, which are each filled (on the present system of planting this garden) with a mass of only one kind of some handsome flowering plant. These are oftener tall-growing plants than dwarf bedding plants, and their upper stems and branchlets, laden with flowers, bend and sway in the wind, like the surface of a lake gently moved by a summer breeze—

And o’er them lights and shadows pass,
Like lights and shades on waving Grass,—

but with a more magical effect, inasmuch as each waving mass is of a different colour—from crimson and purple to the opaline-pearly tints of orange, green, and emerald. It must be confessed, however, that the geometrical principle is sometimes carried to excess; in such devices, for instance, as that of the production in living flowers of the Drummond badge, the red wavy band on a gold ground, an effect produced by a carefully planted band of scarlet or crimson flowers serpentine through a square or shield-formed mass of yellow ones. This, and other effects of a similar kind are, perhaps, scarcely defensible on æsthetic grounds; but the dimensions of the devices are so large (the kind of plants by which they are effected being tall and robust) that effects are produced which quite over-ride the ordinary objections to the small neat fashion of the “bedding system,” which has been satirically called the “pin-cushion style.” The intermixture of free-growing foliage, too, combined with the tall and (I am sorry to add) cropped spires of greenery formed of Yew, Holly, Juniper, and other trees, combine to produce a general effect extremely rich and striking; insomuch, that one might fancy the whole scene the glittering fancy of a passing vision—a waking dream of the gardens of some fairy palace, such as one might read of in mediæval romances. The accompanying engraving represents a perspective view of the upper terrace—a noble piece of semi-rustic masonry, surmounted with vases and busts—above which appears a portion of the modern buildings, and some of the foliage of the high ground on which the castle and modern residence stand. At the time of my visit, last autumn, this terrace-wall was clothed with beautiful climbing plants, most of them ornamental flower-bearers, among which, it appeared to me, that Clematis Jackmanni (with its masses of streaming purple, looking like vast festoonings of velvet or satin, according to the light) most certainly bore off the palm of splendour. The border in front was filled with masses of Canna, Hydrangea, Scotch Thistle (so-called), with its hoary leaves and spines glistening like frosted silver. But to allude to all the plants, by name only, which completed the display of that glorious border, would be a useless recapitulation, as every horticulturist at the present day knows well how to fill a border, even of that extent, and make it, through its whole length, a scene of as great floral splendour as that at Drummond was when I saw it. The lower terraces are equally attractive, though of a different character; but of all the terrace work it is the grand central flight of marble steps, guarded by carved balustrading, and surmounted in suitable places by handsome urns, which is the most decorative and most effective feature, and is the one most frequently selected by artists. It has been transferred to canvas, to paper, and to photographic cardboards, over and over again. The general quality of the statuary and fountain-work of the gardens is not of a high character, but it serves to produce the effect required, and, not being overdone, is a valuable and, indeed, necessary adjunct to gardens of a geometric character. A vase or a statue, forming the closing object of many a long vista of green (such as a turf walk, shadowed on either side by evergreen shrubs), is, indeed, one of the most pleasing features of these extensive gardens. Walks, of the kind described, radiate at many points from the more geometrical portions of the design, and are, in each instance, formed by shrubs of different kinds. The more outlying divisions of the general plan, as they become large by divergence, are filled with detached, well-grown, and slightly-trimmed shrubs, generally evergreens, and these masses have the richest possible effect when seen from the terraces above.

The eventual blending of the gardens with the fine surrounding woods is also one of the agreeable characteristics of the place, and it should be noted that some of the Laurels and Portugal Laurels of the outlying portions of the gardens are

VIEW IN THE GARDENS AT DRUMMOND CASTLE.

of enormous size, some of them having trunks almost as big and stately as those of forest trees. At one point, closely adjoining the woods, there is a bridge over a small stream, which has been partially enclosed, so as to form a rocky pond, well furnished with handsome water plants; and from the bridge, between the trunks of great trees, a picturesque glimpse of the park is obtained, lighted up by the bright waters of one end of the lake, the blue-grey mountains rising beyond it in the far distance. Much more might be told concerning interesting features in and about these celebrated gardens, but enough has been said, aided by the accompanying engraving, to give a fair general idea of their style and aspect. One more feature, however, I cannot avoid dwelling upon for a moment—it is a sort of continuation of the terrace effect, in one direction, by means of a vast green wall of Portugal Laurels of enormous size, with a fine broad walk in front of them. These trees have been cropped into recesses at certain distances, and in each recess is a handsome stone seat. This Topiarian device is scarcely defensible according to the higher codes of law, which are beginning to govern modern gardening as despotically as the geometric system ruled over horticultural proceedings in the days of Le Notre; but, in this instance, its effect is pleasing, and not purposeless; for, on sultry summer afternoons, when the sun is blazing down upon the broad gravelled walk, these sheltered recesses must present themselves as very agreeable retreats for an hour of musing, or reading, or other enjoyment.

INSECT DEVOURING PLANTS.

HOWEVER opposite the parts which animals and vegetables play in the economy of the world, as the two opposed kingdoms of organic nature, it is becoming more and more obvious that they are not only two contiguous kingdoms, but are parts of one whole—antithetical and complimentary to each other, indeed, but such “thin partitions do the bounds divide” that no definitions yet framed hold good without exception. This is a world of transition in more senses than is commonly thought; and one of the lessons which the philosophical naturalist learns, or has to learn, is, that differences, the most wide and real in the main, and the most essential, may nevertheless be here and there connected or bridged over by gradations. There is a limbo filled with organisms which never rise high enough in the scale to be manifestly either animal or plant, unless it may be said of some of them that they are each in turn and neither long. There are undoubted animals which produce the essential material of vegetable fabric, or build up a part of their structure of it, or elaborate the characteristic leaf-green which, under solar light, assimilates inorganic into organic matter, the most distinguishing function of vegetation. On the other hand there are plants—microscopic, indeed, but unquestionable—which move spontaneously and freely around and among animals that are fixed and rooted. And, to come without further parley to the matter in hand, while the majority of animals feed directly upon plants, “for ’tis their nature to,” there are plants which turn the tables and feed upon them. Some, being parasitic upon living animals, feed insidiously and furtively; these, although really cases in point, are not so extraordinary, and, as they belong to the lower orders, they are not much regarded, except for the harm they do. There are others, and those of the highest orders, which lure or entrap animals in ways which may well excite our special wonder—all the more so since we are now led to conclude that they not only capture but consume their prey. As respects the two or three most notable instances, the conclusions which have been reached are among the very recent acquisitions of physiological science. Curiously enough, however, now that they are made out, it appears that they were in good part long ago attained, recorded, and mainly forgotten. The earlier observations and surmises shared the common fate of discoveries made before the time, or by those who were not sagacious enough to bring out their full meaning or importance. Vegetable morphology, dimly apprehended by Linnæus, initiated by Caspar Frederic Wolff, and, again, independently in successive generations by Goethe and by De Candolle, offers a parallel instance. The botanist of Goethe’s day could not see any sense or practical application to be made of the proposition that the parts of a blossom answer to leaves; and so the study of homologies had long to wait.

Fly-catchers.

Until very lately it appeared to be of no consequence whatever (except, perhaps, to the insects) whether *Drosera* and *Sarracenia* caught flies or not; and even *Dionæa* excited only unreflecting wonder as a vegetable anomaly. As if there were real anomalies in

Nature, and some one plant possessed extraordinary powers denied to all others and (as was supposed) of no importance to itself. That most expert of fly-catchers, *Dionæa*, of which so much has been written and so little known until lately, came very nearly revealing its secret to Solander and Ellis a hundred years ago, and, doubtless, to John Bartram, its probable discoverer, who sent it to Europe. Ellis, in his published letter to Linnæus, with which the history begins, described the structure and action of the living trap correctly; noticed that the irritability which called forth the quick movement closing the trap entirely resided in the few small bristles of its upper face; that this whole surface was studded with glands, which probably secreted a liquid; and that the trap did not open again when an insect was captured, even upon the death of the captive, although it opened very soon when nothing was caught, or when the irritation was caused by a bit of straw or any such substance. It was Linnæus who originated the contrary and erroneous statement, which has long prevailed in the books, that the trap re-opened when the fatigued captive became quiet, and let it go; as if the plant caught flies in mere play and pastime! Linnæus also omitted all allusion to a secreted liquid—which was justifiable, as Ellis does not state that he had actually seen any, and, if he did see it, quite mistook its use, supposing it to be, like the nectar of flowers, a lure for insects, a bait for the trap. Whereas, in fact, the lure, if there be any, must be an odour (although nothing is perceptible to the human olfactories); for the liquid secreted by the glands never appears until the trap has closed upon some insect and held it at least for some hours a prisoner. Within twenty-four or forty-eight hours this glairy liquid is abundant, macerating the body of the perished insect. Its analogue is not nectar but the gastric juice. The observations which compel such an inference are recent, and the substance of them may be briefly stated. The late Rev. Dr. M. A. Curtis, forty years and more ago, resided at Wilmington, North Carolina, in the midst of the only district to which the *Dionæa* is native; and he published, in 1834, in the first volume of the “Journal of the Boston Society of Natural History,” by far the best account of this singular plant which had then appeared. He remarks, that “the little prisoner is not crushed and suddenly destroyed, as is sometimes supposed,” for he had often liberated “captive flies and spiders, which sped away as fast as fear or joy could hasten them.” But he neglected to state, although he must have noticed the fact, that the two sides of the trap, at first concave to the contained insect, at length flatten and close down firmly upon the prey, exerting no inconsiderable pressure, and ensuring the death of any soft-bodied insect, if it had not already succumbed to the confinement and salivation. This last Dr. Curtis noticed, and first discerned its import, although he hesitated to pronounce upon its universality. That the captured insects were in some way “made subservient to the nourishment of the plant” had been conjectured from the first. Dr. Curtis “at times found them enveloped in a fluid of mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed in it.” This was verified, and the digestive character of the liquid well-nigh demonstrated, six or seven years ago, by Mr. Canby, of Wilmington, Delaware, who, upon a visit to the sister-town of North Carolina, and afterwards at his home, followed up Dr. Curtis’s suggestions with some capital observations and experiments. These were published at Philadelphia, in the tenth volume of *Mehan’s Gardeners’ Monthly*, August, 1868, but they do not appear to have attracted the attention which they merited. The points which Mr. Canby made out are, that this fluid is always poured out around the captured insect in due time, “if the leaf is in good condition and the prey suitable;” that it comes from the leaf itself, and not from the decomposing insect (for when the trap caught a plum-curculio, the fluid was poured out while he was still alive, though very weak, and endeavouring, ineffectually, to eat his way out); that bits of raw beef, although sometimes rejected after awhile, were generally acted upon in the same manner—i.e., closed down upon tightly, slavered with the liquid, dissolved mainly, and absorbed; so that, in fine, the fluid may well be said to be analogous to the gastric juice of animals, dissolving the prey and rendering it fit for absorption by the leaf. Many leaves remain inactive or slowly die away after one meal; others re-open for a second and perhaps even a third capture, and are at least capable of digesting a second meal. Before Mr. Canby’s experiments had been made, a similar series had been made in England by Mr. Darwin, with the same results, and with a small but highly curious additional one—namely, that the fluid secreted in the trap of *Dionæa*, like the gastric juice, has an acid reaction. Having begun to mention unpublished results (too long allowed to remain so), it may be well, under the circumstances, to refer to a still more remarkable experiment by the same most sagacious investigator. By a prick with a sharp lancet at a certain point, he has been able to paralyze one-half of the leaf-trap, so that it remained motionless under the stimulus to

which the other half responded. Such high and sensitive organisation entails corresponding ailments. Mr. Canby tells us that he gave to one of his *Dionæa*-subjects a fatal dyspepsia by feeding it with cheese; and under Mr. Darwin's hands another suffers from paraplegia. Finally, Dr. Burton-Saunderson's experiments, detailed at the last meeting of the British Association for the advancement of Science, show that the same electrical currents are devolved upon the closing of the *Dionæa*-trap, as in the contraction of a muscle. If the Venus's fly-trap stood alone, it would be doubly marvellous—first, on account of its carnivorous propensities, and then as constituting a real anomaly in organic nature, to which nothing leads up. Before acquiescing in such a conclusion, the modern naturalist would scrutinise its relatives. Now the nearest relatives of our vegetable wonder are the

Sundews.

While *Dionæa* is local, the *Droseras*, or Sundews, are widely diffused. The two whose captivating habits have attracted attention, abound in bogs all round the northern hemisphere. That flies are caught by them is a matter of common observation; but this was thought to be purely accidental. They spread out from the root a circle of small leaves, the upper face of which especially is beset, and the margin fringed, with stout bristles (or what seem to be such, although the structure is more complex), tipped by a secreting gland, which produces, while in vigorous state, a globule of clear liquid like a drop of dew—whence the name, both Greek and English. One expects these seeming dewdrops to be dissipated by the morning sun; but they remain unaffected. A touch shows that the glistening drops are glutinous and extremely tenacious, as flies learn to their cost on alighting, perhaps to sip the tempting liquid, which acts first as a decoy and then like birdlime. A small fly is held so fast, and in its struggles comes into contact with so many of these glutinous globules, that it seldom escapes. The result is much the same to the insect, whether captured in the trap of *Dionæa* or stuck fast to the limed bristles of *Drosera*. As there are various plants upon whose glandular hairs or glutinous surfaces small insects are habitually caught and perish, it might be pure coincidence that the most effectual arrangement of the kind happens to occur in the nearest relatives of *Dionæa*. Roth, a keen German botanist of the eighteenth century, was the first to detect, or at least to record, some evidence of intention in *Drosera*, and to compare its action with that of *Dionæa*, which, through Ellis's account, had shortly before been made known in Europe. He noticed the telling fact that not only the bristles which the unfortunate insect had come in contact with, but also the surrounding rows, before widely spreading, curved inwards one by one, although they had not been touched, so as within a few hours to press their glutinous tips likewise against the body of the captive insect—thus doubling or quadrupling the bonds of the victim, and (as we may now suspect) the surfaces through which some part of the animal substance may be imbibed. For Roth surmised that both these plants were, in their way, predaceous. He even observed that the disk of the *Drosera* leaf itself often became concave and enveloped the prey. These facts, although mentioned now and then in some succeeding works, were generally forgotten, except that of the adhesion of small insects to the leaves of Sundews, which must have been observed in every generation. Up to and even within a few years past, if any reference was made to these asserted movements (as by such eminent physiologists as Meyen and Treviranus) it was to discredit them. Not because they are difficult to verify, but because, being naturally thought improbable, it was easier to deny or ignore them. So completely had the knowledge of almost a century ago died out in later years that, when the subject was taken up anew, in our days, by Mr. Darwin, he had, as we remember, to advertise for it, by sending a "note and query" to the magazines, asking where any account of the fly-catching of the leaves of Sundew was recorded. When Mr. Darwin takes a matter of this sort in hand, he is not likely to leave it where he found it. He not only confirmed all Roth's observations as to the incurving of the bristles towards and upon an insect entangled on any part of the disk of the leaf, but also found that they responded similarly to a bit of muscle or other animal substance, while to any particles of inorganic matter they were nearly indifferent. To minute fragments of carbonate of ammonia, however, they were more responsive. As these remarkable results, attained half a dozen years ago, remained unpublished (being portions of an investigation not yet completed), it would have been hardly proper to mention them, were it not that independent observers were beginning to bring out the same, or similar facts. Mrs. Treat, of New Jersey, noticed the habitual enfolding of the leaf in the longer-leaved species of Sundew (*American Journal of Science* for November, 1871), as was then thought for the first time—Roth's and Withering's observations not having been looked up. In recording this, the next year, in a very little book, entitled "How Plants Behave," the opportunity was taken to men-

tion, in the briefest way, the capital discovery of Mr. Darwin, that the leaves of *Drosera* act differently when different objects are placed upon them, the bristles closing upon a particle of raw meat as upon a living insect, while to a particle of chalk or wood they are nearly inactive. The same facts were independently brought out by Mr. A. W. Benett at last year's meeting of the British Association for the Advancement of Science, and have been mentioned in the journals. If to these statements, which we may certify, were added some far more extraordinary ones, communicated to the French Academy of Science, in May last, by M. Zeigler, a stranger story of discrimination on the part of Sundew-bristles would be told. But it is safer to wait for the report of the committee to which these marvels were referred, and conclude this sufficiently "strange, eventful history" with some details of experiments made last summer by Mrs. Treat, of New Jersey, and published in the December number of the *American Naturalist*. It is well to note that Mrs. Treat selects for publication the observations of one particular day in July, when the Sundew leaves were unusually active; for their modes vary with the weather, and also in other unaccountable ways, although, in general, the sultrier days are the most appetising:

At fifteen minutes past ten of the same day I placed bits of raw beef on some of the most vigorous leaves of *Drosera longifolia*. Ten minutes past twelve, two of the leaves had folded around the beef, hiding it from sight. Half-past eleven of the same day, I placed living flies on the leaves of *D. longifolia*. At 12° 48' one of the leaves had folded entirely around its victim, the other leaves had partially folded, and the ifes had ceased to struggle. By 2° 30' four leaves had each folded around a fly. . . . I tried mineral substances—bits of dry chalk, magnesia, and pebbles. In twenty-four hours, neither the leaves nor their bristles had made any move like clasping these articles. I wet a piece of chalk in water, and in less than an hour the bristles were curving about it, but soon unfolded again, leaving the chalk free on the blade of the leaf. Parallel experiments made on *D. rotundifolia* with bits of beef and of chalk gave the same results as to the action of the bristles; while with a piece of raw Apple, after eleven hours, "part of the bristles were clasping it, but not as closely as the beef," and in twenty-four hours "nearly all the bristles were curved towards it, but not many of the glands were touching it."

To make such observations is as easy as it is interesting. Throughout the summer one has only to transfer plants of *Drosera* from the bogs into pots or pans filled with wet Moss; if need be, allowing them to become established in the somewhat changed conditions, or even to put out fresh leaves, and to watch their action or expedite it by placing small flies upon the disk of the leaves. The more common round-leaved Sundew acts as well as the other by its bristles, and the leaf itself is sometimes almost equally prehensile, although in a different way, enfolding the whole border instead of the summit only. Very curious, and even somewhat painful, is the sight when a fly, alighting upon the central dew-tipped bristles, is held as fast as by a spider's web; while the efforts to escape not only entangle the insect more hopelessly as they exhaust its strength, but call into action the surrounding bristles, which, one by one, add to the number of the bonds, each by itself apparently feeble, but in their combination so effectual that the fly may be likened to the sleeping Gulliver made fast in the tiny but multitudinous toils of the Lilliputians. Anybody who can believe that such an apparatus was not intended to capture flies might say the same of a spider's web. Is the intention here to be thought any the less real because there are other species of *Drosera* which are not so perfectly adapted for fly-catching, owing to the form of their leaves and the partial or total want of co-operation of their scattered bristles? One such species, *D. filiformis*, the thread-leaved Sundew, is not uncommon in America, both north and south of the district that *Dionæa* locally inhabits. Its leaves are long and thread-shaped, beset throughout with glutinous gland-tipped bristles, but wholly destitute of a blade. Flies, even large ones, and even moths and butterflies, as Mrs. Treat and Mr. Canby affirm (in the *American Naturalist*), get stuck fast to these bristles, whence they seldom escape. Accidental as such captures are, even these thread-shaped leaves respond more or less to the contact, somewhat in the manner of their brethren. In Mr. Canby's recent and simple experiments, made at Mr. Darwin's suggestion, when a small fly alights upon a leaf a little below its slender apex, or when a bit of crushed fly is there affixed, within a few hours the tip of the leaf bends at the point of contact, and curls over or around the body in question; and Mrs. Treat even found that, when living flies were pinned at half an inch in distance from the leaves, these in forty minutes had bent their tips perceptibly towards the flies, and in less than two hours reached them! If this be confirmed—and such a statement needs ample confirmation—then it may be suspected that these slender leaves not only incurve after prolonged contact, just as do the leaf-stalks of many climbers, but also make free and independent circular sweeps, in the manner of twining stems and of many tendrils. Correlated movements like these indicate purpose. When performed by

climbing plants, the object and the advantage are obvious. That the apparatus and the actions of *Dionæa* and *Drosera* are purposeless and without advantage to the plants themselves, may have been believed in former days, when it was likewise conceived that abortive and functionless organs were specially created "for the sake of symmetry?" and to display a plan; but this is not according to the genius of modern science.

Sarracenias.

In cases of insecticide, next to be considered, such evidence of intent is wanting; but other and circumstantial evidence may be had sufficient to warrant conviction. *Sarracenias* have hollow leaves, in the form of pitcher or trumpet-shaped tubes, containing water, in which flies and other insects are habitually drowned. They are all natives of the eastern side of North America, growing in bogs or low ground, so that they cannot be supposed to need the water as such. Indeed, they secrete a part, if not all, of it. The commonest species, and the only one at the north, which ranges from Newfoundland to Florida, has a broad-mouthed pitcher with an upright lid, into which rain must needs fall more or less. The yellow *Sarracenia*, with long tubular leaves, called "trumpets" in the Southern States, has an arching or partly upright lid, raised well above the orifice, so that some water may rain in; but a portion is certainly secreted there, and may be seen bedewing the sides and collected at the bottom before the mouth opens. In other species the orifice is so completely overarched as essentially to prevent the access of water from without. In these tubes, mainly in the water, flies and other insects accumulate, perish, and decompose. Flies thrown into the open-mouthed tube of the yellow *Sarracenia*, even when free from water, are unable to get out—one hardly sees why, except that they cannot fly directly upwards; and a microscopic *chevaux-de-frise* of fine sharp-pointed bristles which lines most of the interior, pointing strictly downwards, may be a more effectual obstacle to crawling up the sides than one would think possible. On the inside of the lid or hood of the purple northern species the bristles are much stronger; but an insect might escape by the front without encountering these. In this species the pitchers, however, are so well supplied with water that the insects, which somehow are most abundantly attracted thither, are effectually drowned, and the contents all summer long are in the condition of a rich liquid-manure. That the tubes or pitchers of the southern species are equally attractive and fatal to flies is well known. Indeed, they are said to be taken into houses and used as fly-traps. There is no perceptible odour to draw insects, except what arises from the decomposition of macerated victims; nor is any kind of lure to be detected at the mouth of the pitcher of the common purple-flowered species. Some incredulity was therefore natural when it was stated by a Carolinian correspondent (Mr. B. F. Grady), that in the long-leaved, yellow-flowered species, the lid just above the mouth of the tubular pitcher habitually secretes drops of a sweet and viscid liquid, which attracts flies and apparently intoxicates them, since those that sip it soon become unsteady in gait and mostly fall irretrievably into the well beneath. But, upon cultivating plants of this species, obtained for the purpose, the existence of this lure was abundantly verified; and although we cannot vouch for its inebriating quality, we can no longer regard it as unlikely. No sooner was it thus ascertained that at least one species of *Sarracenia* allures flies to their ruin, than it began to appear that—just as in the case of *Drosera*—most of this was a mere revival of obsolete knowledge.

The Insect Destroying Process.

This was well described sixty years ago, the part played by the sweet exudation indicated, and even the intoxication hinted at, although evidently little thought of in those ante-temperance days. Dr. James Macbride of South Carolina—the early associate of Elliott in his "Botany of South Carolina and Georgia," and to whose death, at the age of thirty-three, cutting short a life of remarkable promise, the latter touchingly alludes in the preface to his second volume—sent to Sir James Edward Smith an account of his observations upon this subject, made in 1810 and the following years. This was read to the Linnean Society in 1815, and published in the twelfth volume of its "Transactions." From this forgotten paper (to which attention has lately been recalled) we cull the following extracts, promising that the observations mostly relate to a third species, *Sarracenia adunca*, *alias* *variolaris*, which is said to be the most efficient fly-catcher of the kind:

If, in the months of May, June, or July, when the leaves of those plants perform their extraordinary functions in the greatest perfection, some of them be removed to a house and fixed in an erect position, it will soon be perceived that flies are attracted by them. These insects immediately approach the fauces of the leaves, and, leaning over their edges, appear to sip with eagerness something from their internal surfaces. In this position they linger; but at length, allured, as it would seem, by the

pleasure of taste, they enter the tubes. The fly, which has thus changed its situation, will be seen to stand unsteadily; it totters for a few seconds, slips, and falls to the bottom of the tube, where it is either drowned or attempts, in vain, to ascend against the points of the hairs. The fly seldom takes wing in its fall and escapes. . . . In a house much infested by flies, this entrapment goes on so rapidly that a tube is filled in a few hours, and it becomes necessary to add water, the natural quantity being insufficient to drown the imprisoned insects. The leaves of *S. adunca* and *rubra* [a fourth species] might well be employed as fly-catchers; indeed, I am credibly informed they are in some neighbourhoods. The leaves of the *S. flava* [the species to which our foregoing remarks mainly relate], although they are very capacious, and often grow to the height of 3 feet or more, are never found to contain so many insects as those of the species above mentioned.

The cause which attracts flies is evidently a sweet viscid substance, resembling honey, secreted by or exuding from the internal surface of the tube. . . . From the margin, where it commences, it does not extend lower than one-fourth of an inch.

The falling of the insect as soon as it enters the tube is wholly attributable to the downward or inverted position of the hairs of the internal surface of the leaf. At the bottom of a tube split open, the hairs are plainly discernible pointing downwards; as the eye ranges upward, they gradually become shorter and attenuated, till at, or just below, the surface covered by the bait, they are no longer perceptible to the naked eye nor to the most delicate touch. It is here that the fly cannot take a hold sufficiently strong to support itself, but falls. The inability of insects to crawl up against the points of the hairs I have often tested in the most satisfactory manner.

From the last paragraph it may be inferred that Dr. Macbride did not suspect any inebriating property in the nectar, and in a closing note there is a conjecture of an impalpable loose powder in *S. flava*, at the place where the fly stands so unsteadily, and from which it is supposed to slide. We incline to take Mr. Grady's view of the case. The complete oblivion into which this paper and the whole subject had fallen is the more remarkable when it is seen that both are briefly, but explicitly, referred to in Elliott's book, with which botanists are familiar. It is not so wonderful that the far earlier allusion to these facts by the younger Bartram should have been overlooked or disregarded. Fine writing was his foible; and the preface to his well-known "Travels" (published at Philadelphia in 1791) is its full-blown illustration, sometimes, perhaps, deserving the epithet which he applies to the Palms of Florida—that of pomposity. In this preface he declares that "all the *Sarracenias* are insect-catchers, and so is the *Drosera rotundifolia*." "Whether the insects caught in their leaves, and which dissolve and mix with the fluid, serve for aliment or support to these kinds of plants, is doubtful," he thinks, but he should be credited with the suggestion. In one sentence he speaks of the quantities of insects which, "being invited down to sip the mellifluous exuvia from the interior surface of the tube, where they inevitably perish," being prevented from returning by the stiff hairs all pointing downwards. This, if it refers to the sweet secretion, would place it below, and not, as it is, above the bristly surface.

Why should these plants take to organic food more than others? If we cannot answer the question, we may take a probable step towards it. For plants that are not parasitic, these, especially the Sundews, have much less than the ordinary amount of chlorophyll—that is, of the universal leaf-green upon which the formation of organic matter out of inorganic materials depends. These take it, instead of making it, to a certain extent. What is the bearing of these remarkable adaptations and operations upon doctrines of evolution? There seems here to be a field on which the specific creationist, the evolutionist with design, and the necessary evolutionist, may engage in an interesting, if not decisive, "triangular duel." [For the foregoing article, lately published in the *New York Nation*, we are indebted to the author, who kindly furnished us with the papers in which it appeared.—ED.]

Sulphate of Iron and Vegetation.—M. Eusebe Gris has been making experiments on the influence of sulphate of iron on vegetation, and comes to these conclusions—that the salt is a stimulating manure; that it presents no danger when intelligently applied; that its action is evident upon the colouring principles of leaves; that from its cheapness a few cents' worth is sufficient to treat hundreds of plants; that it might be applied to cultivation on a large scale, and especially to the cultivation of fruit. His manner of applying the sulphate is as follows:—A solution of two drachms to one quart of water is made, and with this the plants, previously placed in the shade, are watered. It is presumed that the earth surrounding the plant is moist; if this is not the case, a more dilute solution must be used. The solution may be applied daily for five or six days; about two-and-a-half ounces are sufficient for each watering of an ordinary-sized plant, as a *Calceolaria*.

THE INDOOR GARDEN.

DIPLADENIA BREARLEYANA.

THIS, one of the best of all the Dipladenias, has flowered beautifully in Mr. Bull's establishment in the King's Road, where its blossoms, being, as will be seen by the accompanying illustration, of large size, have been most effective. When they first open, they are of a pale rose colour; but, afterwards, they

drained. In order to bloom these plants in perfection, they must be grown on vigorously, without a check, until the pots, into which they are shifted to flower, become filled with roots, and kept free from insect pests, to which they are especially liable if subjected to irregular treatment. As the plants make their growth, thin out the weakest shoots, and re-pot them as required. When the pots become filled with roots, a little clear manure-water will be found beneficial in strengthening the remaining shoots and in improving the colour of the

Dipladenia Brearleyana.

change to brilliant crimson, each flower, when fully expanded, measuring fully 5 inches in diameter. Like the rest of the genus, to which it is a valuable addition, it is a plant of comparatively easy culture. Dipladenias are readily propagated by means of cuttings, plunging the cutting-pots in a mild bottom-heat, and keeping them moderately moist until rooted; after that they should be potted off into small pots, using a fresh compost of fibrous loam, leaf-mould, and sand. To this, some growers add one-fourth or more of fibrous peat; but the former ingredients are sufficient, if the pots are thoroughly well

foliage. During the growing season they should be syringed two or three times daily, not only as a means of promoting vigour, but as a preventive of the ravages of red spider.

PLUNGING AND DIS-ROOTING BRUGMANSIAS.

A VERY slight modification in the culture of a plant is often found to be a matter of a good deal of importance. I allude more particularly to *Brugmansia arborea*, *B. suaveolens*, and *B. frutescens*, but the same remark is also applicable to *B. sanguinea*. Taking it

for granted that the plants have been properly cultivated for three years from the first blooming in pots plunged each summer in the open garden, and kept in winter in a greenhouse, duly watered and shifted each year into larger pots, they should be, say, about 4 or 5 feet high, with four or five primary branches at that height. The usual course after this period, if it be not intended either to throw the plants away or to continue increasing the size of the pots indefinitely, would be to plant them without pots, or to plunge the pots with their rims so far below the surface as to allow the roots free access to the open ground above the pots. When lifting time comes round, if you have not plenty of border under glass to replunge your plants, but must place them side by side, as lifted, under glass, or in a cellar, or outhouse, it becomes impossible to water the balls properly, from the water running off, the spongioles dry up, and, in addition to the usual damping off of the herbaceous extremities of the plant, it will generally be found in spring that the want of properly preserved spongioles by a due degree of moisture, has caused one or more of the primary branches to die away, thus completely disfiguring the tree. My modification is this, unpot the ball, take out the crocks, and enlarge the hole by chipping with a chisel to the size, say, of half-a-crown, replace the ball without any crocks, and plunge the pot, leaving the rim above ground, water as usual, but within the pot, and in a short time the roots will dive downwards through the hole, causing the plant to thrive and bloom as magnificently as if it were planted without a pot. In autumn, cut off the external roots even with the bottom of the pot, then house as usual, and it will be found that a little water now and then will keep those spongioles all right, which have been kept growing within the pot all summer, and the plants will never lose a branch, *i.e.*, if duly ventilated and not under drip; and so, from year to year, you can keep the same plant blooming and thriving, not indefinitely, of course, but quite long enough to be a great boon to those having but small gardens, little house room, and unable to keep up a regular rotation of cuttings to renew the rejected plants. I have kept in this way, for many years, various huge and unwieldy *Opuntias* and *Cereuses*, and anyone having kept a regular collection of Cacti is aware what a nuisance they become when the size of the pot is yearly increased. Those who have not tried it will be astonished at the wonderful growth which slow-growing Cacti will make in one single summer when grafted upon one of these old *Opuntias* or *Cereuses*, left to run loose through an open bottom, as compared with what they would do upon the same plant starving in its pot under scorching glass, and always, more or less, infested with vermin. The same method may be applied to almost any greenhouse woody plant which is quiescent during the winter and will thrive in the open garden during summer. It provides for that very slight and slow motion of the sap which constitutes the life of the hibernating plant, and is only apparent to the observer when, by its total cessation, it shows us the plant shrivelling, dying, and, finally, dead. FREDK. PALMER.

Versailles.

Euphorbia splendens.—The genus to which this species belongs is a very extensive one; but few of its members are worth cultivation as decorative plants, but these, few though they are, are so useful and valuable as winter and spring-blooming plants, that we never care to be without their flowers when they are to be had. For bouquets and button holes they are extremely handy, and their coral-tinted blossoms set off white or lilac flowers to the best advantage, and have the additional good property of lasting long after being cut from the plant. *E. jacquiniæflora* is one of the finest, and its wreaths of orange-scarlet flowers come in very usefully as natural wreaths for ladies' hair, or separate flowers set off a button-hole bouquet admirably; this plant, however, only blooms during the winter and spring. The best species for perpetual flowering is the old *E. splendens*, a formidable plant with thick branches, armed at all points with stout spines. It has bright-green foliage and clusters of vermilion or scarlet flowers larger than those of the last-named plant, although not quite so vivid in colour. A plant of this species should be included in every select list of flowering plants grown for a supply of cut bloom.—B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Scutellaria pulchella.—This is a dwarf blue-flowering Labiate, well worth growing in the plant-stove for variety. It is readily propagated from cuttings struck in a gentle bottom-heat under a bell-glass, or close shade, and flowers freely when only a few inches high. *S. violacea* is similar in habit, but has darker violet-purple flowers.—B.

Toxicophlœa spectabilis.—I often wonder that this plant is not more seen in collections than it is, especially as it blooms freely and lasts long in perfection. I bought a plant of it some time ago, potted it in turfy loam and peat on a well-drained bottom, and it grew well, and has borne a fine crop of its pure white flowers. These last are produced in the axils of the deep glossy green foliage, and emit an agreeable perfume. I consider it one of the most useful of all warm greenhouse plants.—J. B. S.

A FLOWER SERMON.

"CONSIDER the Lilies, how they grow," said our Saviour; "they toil not, they spin not—yet Solomon, in all his glory, was not arrayed like one of these." One day I visited our Horticultural Exhibition. A placard gave notice that the subject of the day's discussion was to be the Lily; so I went in to hear the gardeners "consider the Lilies, how they grow." The Japan Lily was the special subject of the talk—how the stranger could be made to grow among ourselves. One man told of his greenhouse luck, and another of his pot-luck, and the next one talked of soils; and so on round the circle. And all the while the superb things stood upon their stalks and looked at us—king, in all his glory, arrayed like one of them! That is almost the only tender word about flowers in all the Bible. In the books of the Apocrypha and the Song of Solomon, Roses and Lilies are mentioned twice or thrice in the lover's way; but the Hebrew feeling for Nature was rather the feeling of its sublimity than its beauty. The sun and stars, the mountains, and the desert, and the sea, the rains, the lightening, and the earthquake—these stand forth in the Old Testament imagery. And trees were loved, and fruit was praised; but Grass and leaves are scarcely spoken of, save as the emblem of withering ("All flesh is Grass," "We all do fade as a leaf"); and, when the Hebrew thought of fragrance, he thought of myrrh and frankincense rather than of Roses; and, when he thought of beauty, a gem, rather than a blossom, was the wonder to his eye. Many a flash of ruby, and sapphire, and emerald gleams from the Bible pages. The wall of the New Jerusalem is built up of them, and its twelve gates are twelve pearls; and in that city is a tree of life, and it has twelve fruits, indeed; but never a word of flowers in that heaven on earth that was to be. Paul was too earnest in his gospel of repentance, and too deep in the love of God to man, to think of the love of God to the hill-sides, and the good news printed off in illuminated text through all the fields; so this little verse of Jesus stands almost alone, to make us know that there was one pair of eyes at least in Palestine that saw the Father everywhere. It is one of the verses that show that Jesus was no common man.

Spring and Flowers.

What would the spring be without the flowers! And yet a spring with flowers is a modern improvement. For ages and ages, through far the greater part of its life thus far, a flowerless earth turned its sombre face up to the sun. It had not learned to smile. All winter we warm ourselves with the ancient sunshine of springs and summers in the far-off past that made the trees that make our coal-beds. But the spring times of those carboniferous ages had no flowers, no fruit-blossoms, no Grass, and of course no bees, and no song-birds, in them! All the plants, the wise men say, were like our Ferns or our Club Mosses, or our meadow Horse-tails, only they "were giants in those days," or else, like our cone-bearing trees, all reproducing in the secret way the Ferns still know, or the quiet way the Pine-cones have. Not till long, long ages afterwards did the earth bear blossoms. Thinking of that we cannot say "The good old times!" We thank Heaven that the birds and flowers came before us. Indeed, the earth had to be ripe for them before it could be ripe for us. So here we are to-day, and the whole land is laughing for us—laughing in Grass and flowers. Great tribes of beings have been already born, and others are on their way into existence, to people the planet again with colour and beauty. What place on it shall have the fairest? Where will the Great Gardener walk and work most fondly? On the broad stretches of prairie, floor paved with gay mosaic? Or in the secret places of the woods? Or in our meadows? No, none of these—for Dr. Hayes says he never saw such beautiful wild-flowers as he found in the Arctic zone, where the summer is almost counted by hours! And Ruskin, with his mountain-love, claims the noblest for the uplands. The Grass grows nowhere softer and greener than on the Alpine pastures; and set out of the glaciers, nestled by eternal snows, rise rocks whose bright tops are gardens of Anemones and Gentians. The Great Central Plain of California for six months of the year is a scorched and dust-swept desert. In April it becomes one flower-bed nearly 400 miles long and thirty wide, set there under the snow mountains. A traveller writes of it: "Go where I would, east, west, north, south, I still plashed and rippled in flower-gems. More than a hundred flowers touched my feet at every step, closing above them as if I were wading in water." To count the riches he gathered the harvest of 1 square yard of plain, taken at random like a cupful of water from a lake, and it gave more than 7,000 distinct flower-heads besides 1,000 stems of silky Grasses, these rising from an inch-deep velvet floor containing by estimate a million of the tiny cups and hoods that we call Mosses. Where then, is the place of the fairest seeing that all eyes claim it for their own? Nay, which one of all these children of the sun is fairest? Thoughts about beauty turn into poetry of themselves. And one can hardly think about flowers with

out twining his words with verse. Let me quote, at least, this one delicate answer to our question—Which one is the fairest?

LA FLOR DEL SALVADOR.

The Daffodil sang, "Darling of the sun
Am I, am I that wear
His colour everywhere!"
The Violet pleaded soft in undertone:
"Am I less perfect made,
Though hidden in the shade
So close and deep, that heaven may not see,
Its own fair hue in me?"
The Rose stood up, full-blown,
Right royal as a queen upon her throne:
"Nay, but I reign alone,"
She said, "with all hearts for my own."
One whispered with faint flush not far away,
"I am the eye of day,
And all men love me;" and, with drowsy sighs,
A Lotus, from the still pond where she lay,
Breathed—"I am precious balm for weary eyes."
Only the fair field Lily, slim and tall,
Spake not for all—
Spake not, and did not stir,
Lapsed in some far and tender memory.
Softly I questioned her,
"And what of thee?"
And winds were lulled about the bended head,
And the warm sunlight swathed her as in flame,
While the awed answer came—
"Hath He not said?"

The flowers are children of the sun, I said. Literally so. The sun makes these as actually as it makes the clouds. It is sun-stir, that motion in the earth-atoms which continually unbuilds and builds them up anew. All things take part in the great circulations of the system. It is heat and light that organise the minerals into root and stem and leaf, and then green leaf still higher into flower-organs. Emerson's verse holds simple fact:—

Heat gives the Reed and Lily length,
Adds to Oak and oxen strength.

Earth and sun—it takes them both to make a Clover-head! And the flowers show their kinship with the sun by waiting on it punctually. As he takes his station in the heavens above, they take theirs in the fields below. Spring is spring for each flower separately, and the gay procession of life marches in in order. We can predict the coming banners. We can date the passing weeks by flower-arrivals and departures—can count the quick hours by flower-wakings and flower-closings. But, without thinking of these upper sympathies that possess the little souls of our dumb spring angels, what a marvel is each one in itself, in its own make and stature! Think what the mathematics of the leaf-arrangement imply—that every leaf on every budding tree, in this whole spring, is set in its place by law! that not one has stumbled to its twig, or to its station on the twig, by any accident! and that this same ordered stationing can be traced all through the close phalanx of the Pine-cone's scales, and determines where the limbs shall start on every tree, and the very spot within the blossom where each stamen shall droop or nod.

Form, Colour, and Fragrance.

That last word touches the greatest flower-secret that has thus far been discovered. The high-school boys all know it now, but the wisest men were just high enough a century ago to guess it; and its outcome, the thought involved in it, has rechristened all our modern science. It is the secret that the botanics call metamorphosis, but, in its grander name transfiguration, evolution, the secret that every organ of the flower is but a transformed leaf; that bud-scale, bract, and sepal, and petal, and stamen, and pistil, back to the new bud-scale, in spite of all the difference of their forms and all their various tintings, are but successive leaf transfigurations. Economic Nature gets her new effects, not by selecting new themes, but by playing variations on the old themes; and when she makes a blossom on an Apple tree or on a pasture-weed, she only shortens and alters what would else have been a common leafy branch. How do we know it? By tracing the cousinship of each pair of neighbour organs through graded series of transitional forms; by watching the conversion and the reconversion of these organs into each other in domesticated double flowers; by studying the cases of monstrosity that so often blab nature's riddles and reveal the latent tendencies of beings. On such full evidence as this we know it. But, not content with such transfiguration, the mother of all beauty takes up the separate organs and tenderly carries out her variations on each one. She bears fixed laws in mind, and never really forgets her arithmetic—the rules of twos and threes and fours and fives;

but, by multiplying parts, by dividing parts, by joining them at this place on their edges and then at that, by enlarging some and making others smaller, by their complete abortion sometimes, by moulding horns and cups, by unfurling wings, by hanging bells and ravelling fringes out, by all sorts of dainty devices of sculpture, she makes the myriad distinct species of miracles that men stare at untiringly as the flowers of spring. It is rare luck, in some old classic land, to turn up from the soil the fragment of a marble statue of great beauty. But Nature, she flings her carvings everywhere above the ground—each one complete and fresh and perfect in its niche, and such a joy that, were it the lone one of its race, it would draw the nations into pilgrimage for its worship. She paints them, too; she gives them colour. If any one seems ugly, as a whole, take a bit and put it under a microscope, and see what firmaments of colour, what mines of sparkling gems, you have burst into! Under the lens a quarter-inch of rosy petal flushes and spreads like a sunset sky! A mottled streak turns into a glorious sunrise! You can think of nothing else for fit comparison. And then, instead of speech, she gives them fragrance. They have no language, but in this way "their music goes forth through all the earth, and their word to the end of the world." Unless, indeed, Huxley's fancy be true, and by ears fine enough (possibly only insect fine), a voice also could be heard, "a beauty born of murmuring sound" would pass into our face as we bent over them—sound such as streams have that run through secret channels. If so, what choruses rise through all our fields that some one hears!

The Flower Weddings.

But what is all this lavish sculpture and painting and fragrance for?—lavished on the waste where no eyes see as well as in the garden bed, lavished on the inner slopes and curves where human eyes cannot detect it, as well as on the inch of outward surface. We used to say, God made it so! we used to say, see His delight in simple beauty by itself! We used to say:—

If eyes were made for seeing,
Then beauty is its own excuse for being;

but to-day again steps forward with a new and better word, and hints—not that the beauty is not beauty—that use is the end, and that all this beauty and fragrance is but a path to that end. We can see plainly enough that all the energy of the plant goes to secure reproduction, that all the parts of the flower subserve the purpose of seed-making. Deep hidden within the flower's heart lies the little nursery where the seeds are to be born; most cunningly the pistil and the stamen watch each other like true lovers for a greeting; tenderly the petals close around them in the cool, and open through fit hours of sunlight. And when the stamens and the pistils cannot meet directly, but the message must be borne by insect rovers, then the complication of contrivance to secure the transport of the message almost exceeds belief. The pollen must be brought from one certain spot in one flower and left upon a certain spot upon another. Says one, speaking of Darwin's search into the fertilisation of the Orchids: "'Moth-traps and spring-guns set on these grounds' might well be the motto of these flowers. There are channels of approach along which the nectar-loving insects are surely guided so as to compel them to pass the given spots; there are adhesive plasters nicely adjusted to fit their probosces or to catch their brows, and so unload their pollen-burden; sometimes where they enter for the honey there are hair-triggers carefully set in their necessary path, communicating with explosive shells that project the pollen-stalks with unerring aim upon their bodies." And now Darwin adds to his explanations the thought (it is not yet wholly proved, but it is well advanced in proof) that the lustrous colours of the flowers and their rich odours are also contrivances to aid in the reproduction. He has found it "an invariable rule that flowers fertilised by the wind never have the gaily-coloured petals," and draws the inference that the beauty and the fragrance come upon the blossoms by long processes of natural selection, because attractive to the insects that are needed to assist in fertilising them. The colours and the songs of birds and insects, he shows in part, are similarly brought about—and thus all that gives the life and motion and peculiar gladness to the fields in spring would be literally but the deep in-breathing of the spirit of love in Nature. When we "consider" the flowers, and find such thoughts as these all waiting for us, the words of Tennyson grow very real to us:—

Flower, in the crannied wall,
I pluck you out of the crannies,
Hold you here, root and all, in my hand,
Little flower; but if I could understand
What you are, root and all, and all in all,
I should know what God and man is!

But I must leave the flowers themselves to speak a word about flower love. The Arabs, passing a rich harvest-field or a tree in full

bloom, will greet it with a "Barak-Allah!"—May God bless you! That hints the world-wide feeling. And the Arab beggars name their children Ruby and Diamond, Li-y, Rose, and Jessamine. So still do we. Gems and flowers, each the highest product of its kingdom, for a gem is the exquisiteness of flint or clay, and flower the transfiguration of the plant; instinctively and fitly we take them to name all other things precious and beautiful.

Flowers in Art and Poetry.

Art has always fed itself on flowers. Architecture tells the story earliest. The heavy Egyptian column imitates, it is supposed, the Palm tree's trunk, and its capital the Lotus bud of the Nile. The Corinthian capital is the Acanthus leaf, and the stones of Gothic architecture conspire in a hundred forms to imitate the vegetable structure. Poetry is full of flower fields, because each flower seems so full of poetry to us. The very flower names are often poems. Some come down to us imperaled with old myth and story and tradition, like the Hyacinth, Narcissus, Solomon's Seal, Arethusa, and the Passion flower. What sacred romances the Lotus flower, the Martyr's Palm, the Victor's Laurel recall! Those long uncouth Greek names we dread in botany, yet there are meanings in them, only they are Greek to us. Heliotrope is "she who turns to the sun;" Mesembryanthemum is simply "flower of the mid-day;" Nasturtium carries its meaning of "bent nose" in its face; Geranium is "crane's bill," let the seed-vessel grow and it will tell the reason why; Saxifrage is rock-cleaver, named so from its birthplace; Anemone is "wind flower." These were all but simple heart and eye names to the Greeks or Romans—each people has its own; just as we call the pets Heartsease, Day's-eye, Morning Glory, Honeysuckle, Mignonette. And when the lovers want to tell the unutterable words they still betake themselves to the dumb messengers that have learned to say so much. There is probably no famous poet that has not sealed his fame into a song about some favourite of the fields. Wordsworth's Celandines and Daffodils are noted, and Burns's Daisy, and Herbert's Rose, and Emerson's Rhodora, and Lowell's Dandelion; while, in Chaucer, the whole spring buds and sings, and all along the lines of Tennyson flowers brush you with fine touches. Nay, every one plays poet with them, though he write no verses. We use them to interpret all the tenderest things in life. When we want to remember a hill-top view, a meeting that has made a holiday, some spot holy with old history, we pluck a flower to make the memory last. If we want to send the home-presence tangibly in a letter, a flower from the window or field close by will carry it best. Old books drop out the "faded yellow blossoms 'twixt page and page," put there "to mark great places with due gratitude." The Californian miner saw the mountain Heartsease where his pick was going to fall, and, before it fell, he was at home across the Continent, quicker than telegrams can fly. And so the flower love, mounting, comes to show itself in man's worship also; and the thought never rises more naturally up to God, than when it rises from bending over flowers. In Buddhist lands they have long been the choicest offering that man brings his Maker, and there are holy blossoms that have symbolised the sun, the world and God's throne! We bring them into church; like visible music they fill the pauses; and who comes here with purer face or life of sweeter obedience to the great laws of Nature! So sweet, so pure, they are, that, like our holiest friends, they fit not joy and wedding moments only but still more naturally they come in together with the tragedies, the silences, the heart-breaks. And why? Is not this the reason:—

When heaven grows dim and faith seeks to renew
The image of its everlasting dower,
I know no argument so sweet as through
The bosom of a flower—
A wicket-gate to heaven (of which death
Is the grand portal sealed to mortal eyes),
Between whose little bars there comes the breath
Of airs from Paradise.

When the "grand portal" has opened and shut close to us, and we are left with straining gaze outside, the "wicket-gate" seems to give comfort. It seems to grant some little vision into the hidden heart of things, suggesting that the darkness everywhere holds possibilities better than our brightest hopes. Save for the flower-fact here before us who could have dreamed that such beauty lurked in the dark earth, was latent in the tiny seed! So we place the flowers round the still cold face; we lay them on our soldiers' graves; we bring them to the sick room, and the bedside of the dying; and everywhere, after words fail and even music hushes, their presence abides—a voiceless, unconfuted argument that the power within all silences and pained and tragedies is love, and that the possibilities of life are infinite. Flowers and art. Flowers and poetry. Flowers and worship. But the flower-thought of all is that I spoke of—growth; and so we add the flowers and science. For in the flower "a new name is written," and that name now is found to have been

written in all things that are. The old name was revelation; it is not false; but the new name, evolution, widens out its meaning. All things grow—all. The flower is type of the universe, and the Lily of the field is solving over again all problems. [The above is a portion of an able discourse, preached at Boston, by the Rev. W. C. Gannett.]

THE PATENT CLIMAX BOILER.

THIS boiler, brought into notice by The Thames Bank Iron Company, Old Barge Wharf, Upper Ground Street, promises to be both powerful and economical. It is made of wrought iron, firmly welded; it will bear great pressure, and, having no joints or sockets connecting the various portions, there is no risk of leakage. It has a water-way back and front, which adds materially to its heating power; there are also within the boiler itself, two side flues, as in the Gold Medal Boiler, and the fire from these flues passes under the mid-feather or wings on each side of the boiler before reaching the chimney shaft. It is fed from the top, and ample space is provided for fuel (any kind of fuel may be used), to last from twelve to

Front elevation.

fifteen hours, or even a longer period than that, so that all night stoking is dispensed with, even in the most severe weather. This boiler, which is patented, is made in various sizes, from 24 inches to 60 inches in length, the smallest being capable of heating 750 feet of 4-inch pipe, and its price is small compared with that of other boilers. It is easily set in brickwork, there being no complicated flues to make or keep clean, and it can be fixed with the ordinary furnace-bars, or the so-called "water-bars." This latter form of fire-bar adds very considerably to the heating power, while there is comparatively little or no risk of leakage. The front water-way, extending down to within 5 inches of the bottom of the boiler, forms a substantial front for brickwork, and as

Cross section through feeder.

the fire-door is only used for lighting the fire or to get out clinkers, it need only be some 6 or 8 inches high, thus dispensing with the ordinary heavy cumbersome door, so often used to the destruction of all brickwork round about it. These boilers do not require any great depth of stoke-hole; for instance, a boiler to heat 2,000 feet of 4-inch pipe can be set in a hole 5 feet deep by 5 feet wide. Those who have tried this boiler, state that its operation is most satisfactory, and that expenditure, in the way of fuel, is reduced by it to a minimum, a great point now-a-days. It will, therefore, doubtless meet with the success which it deserves. It is, in fact, the Gold Medal Boiler, with important improvements.

THE KITCHEN GARDEN.

CULTURE OF THE MOREL BY MEANS OF TAN.

SOME eighteen months ago, attention was called to a method practised by Mr. Laurent Geslin at Bourg-la-Reine, near Paris, of raising Morels like Mushrooms in artificial beds, the latter being formed of horsedung, earth enriched by night-soil, and decayed wood, kept constantly moist and shaded. The recent observations of Messrs. Lorenz and Schollmayr, in Germany, would appear to show that in tan—the spent bark, &c., of the tan-yard—we have another and, perhaps, still more valuable material for promoting the growth of the above highly-prized edible Fungus. Mr. Lorenz, head gardener at Bunzlau, in Silesia, gives the following as his experience with it:—A short time since he had occasion to make a hot-bed for wintering Roses, Verbenas, &c., the lower lining of it 14 to 15 inches in depth, consisting of leaves of the Lime tree; the upper one 9½ inches thick, of tanners' spent bark (Fir mixed with a little Oak bark). Over the two linings was spread a thin covering of the same kind of leaves, and upon this came the frame. Into the beds thus formed the pots were plunged up to the rim; and, according to the state of the weather, the frame was either shaded and protected against the frost, or so arranged as to admit light and air. Owing to this careful management, the plants looked healthy and well in the following spring, when the time arrived for removing them. On taking up some of the pots at the end of March, great, however, was Mr. Lorenz's surprise to find the soil in them, and the whole of the tan in the bed, over-run with a network of fibres and threads resembling Mushroom spawn; nor was his astonishment less, a month or six weeks later, on seeing spring up in his pots a fine crop of Morels. Unfortunately, instead of leaving the bed and pots undisturbed, as he would have done had he been able to foretell the upshot of this fibrous network spread over them, he removed the tan in order to form another bed; and, in the latter, not a trace of a Morel was to be seen. As the Fungus is frequently met with in the neighbourhood of Bunzlau, some spores of the same had doubtless found their way into the tan of the original hot-bed, and thus been placed under circumstances favourable for their development. No opportunity occurred to Mr. Lorenz to make, on the strength of the above experience, a regular trial of tan as a stimulant to the growth of the Morel; but the results obtained by Mr. Schollmayr, director of an experimental farm at Laibach in Carniola, afford strong additional evidence of its efficacy. That gentleman, with a view to check the ravages of the masses of snails and slugs which, year after year, destroyed the buds put forth by young seedling fruit trees in his nursery, covered the ground in the autumn of one year and the spring of the next a foot deep with spent tan, chiefly consisting of Fir bark and Gall-nut meal. The application of this strong-smelling material had the desired effect. For a twelvemonth or more the ground was freed from snails, and the young trees grew vigorously. Another, and quite unexpected result, however—and it is this alone which interests us here, as corroborative of Mr. Lorenz's experience with tan—was the appearance in great quantities of fine, delicately-flavoured Morels; these shooting up most abundantly wherever the top-dressing was thickest and consisted of bigger pieces of bark. The staple soil of the nursery, it should be mentioned, was a poorish sand; and Mr. Schollmayr observed the curious fact that in those spots which—consequent on the heads of the trees being here and there closer together—were more shaded than the rest, the Morel was replaced by another fungus (*Phallus impudicus*). As Mr. Schollmayr's nursery was dug over several times after the Morels ceased to appear the year above alluded to, he had no means of judging how long his dressing of tan might have effected their growth. He does not doubt, however, that if the application were renewed annually, and a suitable situation selected, the cultivator would be rewarded with a plentiful crop. In expressing this opinion he pre-supposes, of course, the existence of a sufficient supply of spores. T. S.

Early Vegetable Culture.—In front of our plant-houses are several very warm early borders; they are not large, but the soil in them has been specially prepared for early cropping to the depth of 3 feet or so. In preparing sites for early crops this labour is of the most profitable kind; as, when once thoroughly done, annual top-dressings afterwards will sufficiently maintain fertility, with, of course, deep stirring of the soil. These warm borders are devoted early in the season to such crops as Potatoes, Cauliflowers, Lettuce, Horn Carrots, and Radishes, making a sort of rotation with each other annually. We usually commence dipping Potatoes from these borders in the open air by the middle of May. This year we took up the first dish on the 12th inst. Such borders are very easily pro-

tected, which, in the case of Potatoes with us is accomplished in this way—stout Ash or Hazel rods have their thick ends planted firmly in the front of the border; they are then bent over and the other ends secured under the wall-plate of the house. A sufficient number of mats is sewn together, so that two pieces will cover all up; two men can easily cover or uncover in a few minutes, and in windy weather a tie or two makes all secure.—E. HODDAR.

Killing Weeds.—There are very few gardens, the soil of which has not been allowed to become filled more or less with the seeds of weeds. When crops spring up, the weeds spring up with them. If numerous, the weeds get above the crops. Hard work at hoeing, and laborious finger weedings follow. The crops are overborne and become small. More weeds give a plentiful seeding another year. With industrious gardeners, who take time by the forelock, much of this trouble and loss is prevented by destroying the weeds when very small. When only half an inch high, the bulk of a weed is not a hundredth part as great as when six inches high. It has not yet drawn a hundredth part as much on the crop and on the soil. A single movement of a steel rake at this early stage will kill fifty weeds; but when they grow six inches high, the rake will do nothing, and the hoe must be ground sharp and applied with many hard strokes. There is a better way still. Kill the weeds broadcast just as they are coming up. The main thing is to do this right. The seeds of nearly all garden weeds are small. Very few will find their way up through two inches of soil. Now, get your ground or beds all ready to plant, but do not plant yet. A little warm weather will start all the seeds for about an inch down; and as soon as you see the first green or yellow point peeping up through the black mould, then is the time for action! Do not wait till next day nor till afternoon, for they will now spring up amazingly fast. Take your steel rake and go over the surface two inches down, raking and cross raking, till you have torn all the delicate little plants to fragments. Now then, there is a pretty fair chance for a clean surface, for very few that are deeper than two inches will get up to the light. It would be safer, however, if you can afford the time, to wait a few days, and give your beds a second raking. If your soil is good, you will go over it thus with great rapidity—twenty times faster than after the sowing of the crops, and you will pulverise the soil admirably. The few days delay will be more than made up by the clean surface, freedom from choking weeds, and by vigorous crops.—Cultivator.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

MAY 20.

THIS exhibition was one of the best that has been held by the Society for several years, nearly all the classes being well represented by fine, well-grown plants. The chief features were stove and greenhouse plants and pot Roses, the former being far above the average. Orchids were scarcely up to the mark, but possibly the inclemency of the weather kept the best specimens at home. Florists' flowers were fine, but limited in quantity, the best being the fancy Pelargoniums of Mr. J. Ward, and the splendid Calceolarias staged by Mr. James and Messrs. Dobson. Some charming cut blooms of Tea-scented and other Roses were furnished by Mr. Geo. Paul, of Cheshunt.

Stove and Greenhouse Plants.—The principle exhibitors of these were Messrs. Jackson, of Kingston, and Mr. B. S. Williams, of Holloway, amongst nurserymen; and Mr. J. Chapman, Mr. J. Ward, and Mr. Kemp among amateurs. Messrs. Jackson had a fine group, in which were Anthurium Scherzerianum, with about thirty brilliant spathes; a fine specimen of the rosy-flowered Pimelea Hendersoni, 4 feet through, and a remarkably good and well-flowered Stephanotis, than which few plants are more effective in a miscellaneous group, especially if, as in this instance, they are contrasted with bright scarlet and purple-flowered plants. Other remarkable plants in this group were Ixora coccinea, bearing great trusses of orange-scarlet flowers, Aphelexis macrantha purpurea and Genetyllis tulipifera, each about four feet through. Mr. B. S. Williams had a well-grown collection, in which were splendid plants of Acrophyllum venosum and Boronia pinnata, both perfect in their way; also, a fine example of the scarlet-spathed Anthurium, but, unfortunately, rather past its best. This group also contained the two best specimen Azaleas in the show, a good Erica Cavendishii, and other well-grown plants. In the amateur class, Mr. Ward had an excellent group, the most remarkable plants in which were Azalea sinensis, a glowing mass of bright yellow flowers; Statice profusa, when well grown, one of the most effective of flowering plants; Erica depressa, E. Cavendishii, a good Anthurium Scherzerianum, and well-bloomed specimens of Aphelexis macrantha, both rosy and purple varieties, being well represented. Mr. W. Chapman followed very closely with a highly creditable and well-finished group, containing a splendid plant of Bougainvillea glabra, a dense mass of bright rosy lilac bracts; Ixora javanica, a perfect specimen, its flowers being well coloured, and the foliage remarkably

fresh and good. The same group also included fine plants of *Erica ventricosa*, *coccinea minor*, and *Pimelea Hendersoni*, each about 3 feet high, and fully as much through; and good specimens of *Azalea Juliana* and *Chorozema Chandlerii*.

Orchids.—The best collections came from Mr. B. S. Williams, Mr. Ward, and Mr. Hill. The last-named exhibitor had the finest specimen Orchid in the show, but, unfortunately, it was staged as a "new plant" instead of as a "specimen orchid," and the result was that it only received a cultural certificate. It was *Dendrobium Falconeri*, bearing some fifty fine richly-coloured flowers. The same exhibitor also had six nice specimens, including a *Vanda suavis*, *V. tricolor*, *Lælia purpurata*, *Masdevallia Lindenii*, with nine or ten flowers, and a good *Phalaenopsis Luddemanniana*. Mr. Child had one of the finest plants of *Oncidium ampliatum majus* we have ever seen, bearing, as it did, great branched flower-spikes fully a yard long. A plant of *Aërides Fieldingii*, in this group, was well bloomed. Mr. J. Wheeler had a nice collection, in which was a good *Dendrobium Bensoniæ*, evidently recently imported. Mr. B. S. Williams had a fine group, in which were excellent examples of *Aërides Fieldingii*, *Oncidium sphacelatum*, *Cattleya Mossiæ*, and others. Mr. Ward had fine plants of *Cypripedium villosum*, *Odontoglossum Pescatorei*, *Lycaste Skinneri*, *Oncidium ampliatum majus*, and a well-grown specimen of *O. crispum*, bearing long flexuose spikes of yellow and brown weird-looking flowers. In the class of six the same exhibitor had a splendid plant of *Odontoglossum Phalaenopsis*, *Phalaenopsis Schilleriana*, with large flowers; *Cypripedium Stonei*, with four spikes; and good plants of *Oncidium sarcodes*, *Phalaenopsis grandiflora*, and *Dendrobium thrysiflorum*.

Roses in Pots.—The competition in the classes devoted to Roses was confined to two exhibitors, viz., Mr. Geo. Paul, of Cheshunt, and Mr. Charles Turner, of Slough, both of whom had fresh well-bloomed plants. The latter contributed nice specimens of *Camille Bernardin*, a rich crimson-purple; *Juno*, rosy flesh, the outer petals nearly white; *Victor Verdier*, deep rose; and *Marie Baumann*, a rich rosy-crimson, and evidently a fine Rose for pot culture. Among the Tea-scented kinds, so valuable for bouquets and floral decorations in a cut state, we noted the President, a flesh-tinted variety with very fine buds; *Madame de St. Joseph*, and *Madame Margottin*, a fine clear sulphur. Mr. Turner's group contained exceptionally fine plants of *Madame de St. Joseph*; *Souvenir d'un Ami*, one of the finest of all flesh-tinted Tea-scented Roses; *Madame Villermoz*, and others previously alluded to. Mr. Geo. Paul furnished ten stands of cut blooms in good condition; and small plants in 8-inch pots, from both exhibitors, were remarkably fresh and well-flowered, just suitable for greenhouse, conservatory, or drawing-room decoration.

Fine Foliage Plants and Ferns.—Some good specimens of Palms and other fine foliaged plants came from Mr. Donald, who had, among others, *Cyathæa dealbata*, *Croton variegatum*, and an excellent plant of *Cycas circinalis*, which, when well grown, is one of the most effective of all Cycads. Mr. Cole, of Ealing Park, had a splendid plant of *Chamærops humilis gracilis*, one of the best of all Palms for a cool greenhouse or conservatory; a good plant of the glossy-leaved *Latania borbonica*, *Seaforthia elegans*, and others. In the nurserymen's class, Mr. Williams had splendidly-grown plants, among which were fine examples of the rare *Gleichenia rupestris*, about 5 feet high, and as much through; *Cycas revoluta*, *Cordylina indivisa*, and one or two richly-coloured *Crotons*. Mr. J. W. Wimsatt had the finest plant of *Maranta Mackoyana* we have yet seen; also a fine specimen of *Croton undulatum*, and excellent examples of *Dracæna amabilis* and *D. Mooreana*. Messrs. Williams, Wimsatt, Croucher, and Butler staged fine groups of Palms, suitable for indoor decoration, and the first-named exhibitor also contributed six well-grown Ferns, among which the most remarkable were—*Gleichenia speluncæ*, *G. flabellata*, *Dicksonia antarctica*, and the choice *Adiantum Farleyense*.

Azaleas and Heaths.—These quite equalled former exhibitions of such plants, the Heaths being especially meritorious. Mr. Ward, Mr. W. Kemp, and Mr. G. Wheeler, represented the amateurs, while Mr. E. Morse and Messrs. Jackson exhibited in the nurserymen's classes. Mr. Ward had good examples of *E. elegans*, *E. ventricosa magnifica*, *E. eximia superba*, *E. Cavendishii*, *E. affinis*, and *E. florida*, each a yard through. Messrs. Jackson had fine plants of *E. Candolleana*, *E. tricolor speciosa*, *E. tricolor superba*, *E. ventricosa grandiflora*. Smaller specimens were staged by Mr. E. Morse and Messrs. Jackson. Fine as these Heaths undoubtedly were, however, they exhibited little or no improvement in the way of varieties on old-established kinds.

A full list of awards is given in our advertisement columns.

Certificates were awarded to the following, viz. :—

Acer septemlobum tricolor (Smith), *A. s. marginatum* (Smith), *A. s. elegans* (Smith), and *A. pictum maculatum* (Smith).—These are all elegant forms of Japanese Maples, many of which promise to play an important part in our landscape scenery.

Agave marmorata (Croucher), *A. micrantha picta* (Croucher), *A. filifera superba* (Croucher), *Echeveria Peacockii* (Croucher), and *Mammillaria Roezliana longispina* (Croucher).—All useful and beautiful additions to a popular class of decorative plants.

Amaryllis virginalis (Williams).—A pure white variety, and very distinct.

Adiantum gracillimum (Williams).

Boronia elatior (Veitch).—A pretty greenhouse plant, with fresh green finely-cut foliage something like *B. Drummondii*, and deep rosy-purple flowers, not fully expanded on the plants exhibited.

Athyrium Filix-femina curtum cristatum (Ivery).—A very beautiful variety of the well-known native Lady Fern. It is likely to be generally cultivated for its beauty, and voted a nuisance on account of its long list of names.

BOTANICAL SOCIETY OF EDINBURGH.

At a meeting of this society, which took place the other day, Mr. M'Nab submitted his report on the open-air vegetation at the Royal Botanic Gardens. In doing so, he said it was not customary to continue his remarks on open-air vegetation beyond the April meeting of the society, but as this spring had been rather of an unusual character as regarded earliness, a few observations in reference to it were worth recording to contrast with seasons which might follow. In his previous reports of this year, beginning with February, it would be found that from the comparatively small amount of continued frosts, also of snow and easterly winds, vegetation commenced at a very early period. Several of those plants selected for recording their flowering, and which usually opened their first blooms during January, and very often in February, were mentioned as flowering in December, thus giving two bloomings in one year, a circumstance which also happened during the early part of the winter of 1863-64. No similar cases had happened with the same species of plants during the twenty-five years that he had been in the habit of recording their dates of bloom. As the past winter had been particularly favourable, vegetation had continued to be from two to three weeks in advance of those hitherto mentioned by him, excepting the spring of 1868. With the exception of the Catalpa and Locust trees, *Celtis occidentalis*, or Nettle tree, *Schubertia disticha*, the deciduous Cypress, and a few Beeches, most others at this date (14th May) presented a rich clothed appearance, while others were in all stages of advancement. Since last meeting, in regard to shrubby plants, vegetation had continued to progress rapidly. Various members of the Hawthorn tribe were in full bloom on the 1st of May—a very unusual circumstance, with the Thorn in Scotland, where, with few exceptions, it was seldom to be seen in bloom before the end of May or beginning of June. This spring has also been very favourable for the flowering of many of the hybrid Rhododendrons, particularly the arborescent forms, many of them being in full bloom in the open air on the 26th of April. Since the last meeting of the society the thermometer had been ten times at and below the freezing point, viz., on the 11th, 12th, 13th, 15th, and 23rd of April, and on the 2nd, 4th, 9th, 11th, and 14th of May, each morning indicating 32°, with the exception of April 13th and May 9th, when it fell to 28°. The highest morning temperatures were on the 20th and 21st of April, indicating 50° and 52° respectively. From a table which Mr. M'Nab submitted, showing the number of degrees of frost registered below the freezing point from 1st October till 30th April for the last eleven winters, it was seen that winters 1865-66, 1867-68, 1868-69, 1871-72 showed fewer degrees of frost than the one just passed, and yet none of them, with the exception of the spring of 1868, exhibited any unusual earliness of vegetation in the month of April and May of these years. In concluding, Mr. M'Nab said that since the 1st of May up to this time a continuance of strong north-easterly winds had been much against the progress of vegetation. Cold, dry winds, with occasional frost at night, were beginning to tell on the early foliage, as well as on many tender herbaceous plants, besides considerably blighting the blossom of the late-flowering fruit trees.

THE INTERNATIONAL HORTICULTURAL EXHIBITION AT FLORENCE.

GREAT flower shows are now become so numerous at home that exhibitions which take place in other countries can hardly possess much interest for English readers who have not the opportunity of seeing them. Besides, foreign exhibitions, like our own, have a monotony as regards the subjects shown, which, after a time, palls. The great Florence show, like most others on the Continent, was mainly distinguished by the presence in abundance of those fine-leaved plants, Tree-ferns, Palms, &c., which are so popular in Continental gardens. They were principally sent from the richly-stored garden of Prince Demidoff at Florence, and from various private and public collections in and near that city. Perhaps the most striking plant of all was the remarkable specimen of *Ruscus androgynus*, spoken of in our account of Prince Demidoff's garden at Florence. Belgian horticulturists also distinguished themselves, as usual, in this department of horticulture; details as to the numerous subjects exhibited in this way can hardly interest the reader, so we omit them. Dr. Moore, of Dublin, exhibited a hybrid *Sarracenia*, between *S. flava* and *S. Drummondii*, and some other interesting pitcher plants. His brother, Mr. Charles Moore, of Sydney, and director of the Sidney Botanic Gardens, brought all the way from his southern home, various tropical fruits, such as the Mango-Jack, Nutmeg, Cashew Nut, and which proved interesting to those only accustomed to the productions of European gardens. Messrs. Veitch were, we believe, the only English exhibitors, and they showed many of their best novelties, and an interesting detachment of their unique collection of Pitcher plants, which were objects of much interest to the Italians, who are not accustomed to see these plants in variety, or in a well-grown condition. Among fruit, the best collections were those of the Orange tribe, which are among the most important products of the country; and some remarkably well-kept Apples and Grapes. Pansies, the culture of which is deservedly popular in Italy, were, of the various subjects known as "florists' flowers" with us, the best grown. The show, which was held in a newly-erected market, was tastefully arranged, and it can hardly fail to spread the love of horticulture in this fair land; in which the march of events has recently prepared the way for progress of all kinds.

In another column we direct the attention of our readers to the possibility of London being selected as the centre for an International Exhibition in 1876.

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WHITE LILAC FORCING.

FOR many years, the forcing of Lilacs in France was a speciality confined to one or two Parisian nurserymen, who kept the process a secret, and to whom it proved a source of vast income, as the flowers, which were pure white, were eagerly sought after, and as the growers of them had no rivals in the trade they were enabled to ask almost any price they pleased for them. Few, however, were then aware that these white Lilacs were produced by forcing the coloured varieties; but this fact is now pretty generally known. The variety used for forcing is that known as the Lilac de Marly. The plants which are intended to be forced should be healthy and vigorous, without having too long-drawn shoots, and it is especially important that they should be old enough to be capable of producing an abundance of flowers. Such plants may be generally obtained after three, four, or five years' culture in a nursery, where they should have been planted at a sufficient distance from each other to allow of the growth of strong thick-set specimens. It is an excellent plan to transplant them once or twice (taking them up with a good ball), as this will cause them to form branchy compact subjects. It also prevents too great a development of the larger roots, while, at the same time, it increases that of the fibres. This facilitates the final lifting from the nursery-ground, and is favourable to success in forcing. Supposing we have such plants of the Lilac de Marly as have been just described, and that we wish to have them in flower in January, we must proceed in the following manner:—In August the plants are to be taken up from the nursery-ground, and carried to the north side of a wall, or other shelter, where they will not be exposed to the sun, but still in the open air. Here they are placed close together, like faggots, standing upright on the ground, the roots being left quite uncovered. The leaves will very soon fall, and the bark will begin to wither and become wrinkled. This, however, should cause no alarm. But, as soon as the bark has become well wrinkled, the stems (not the terminal shoots and branches) should commence to receive slight waterings at such intervals as may be necessary. The object of this is to keep up some degree of vitality in the plants, without, however, exciting them to make any fresh growth. This is a very important point. The plants, in this condition, are to remain where they are placed, in all weathers, until the beginning of December. Should any frost occur in November, as sometimes happens, there is no necessity to shelter them; on the contrary, plants which have been frosted are all the better prepared for forcing. In the beginning of December, forcing should be commenced, that is, if flowers are required by Christmas or New Year's Day. It does not matter much what kind of a house or structure is employed, provided it is large enough to hold the plants (which are sometimes 6 or 7 feet high) without crushing them, and that it is provided with a heating apparatus which will keep up a steady high temperature. Where there is no special structure for this kind of forcing, and the other houses are too low, it is easy, by digging away and lowering the floor, to obtain the desired height, so that the plants, placed erect, with their roots on the ground, may have sufficient room to develop their flowering branches without being pressed against the glass. Failing a plant-house of any kind, a cellar, stable, &c., may be employed, as light is not only not necessary, but absolutely injurious to the operation, the chief points now being to keep the plants in darkness and in the proper temperature. The house being quite prepared, the next step is the introduction of the plants. Supposing flowers are required by the 20th December and the 1st January, it will be necessary, at the end of November, and from the 1st to the 8th December, at the latest, to bring in from the open air the number of plants which it is determined to force. Any earth which remains on their roots should be carefully shaken off; about half the roots should be cut away; all the useless branches, shoots, and twigs—that is, those which do not show flower-buds (which are large, swollen, terminal,

and easily recognised)—should be trimmed off; and, on each of the flowering shoots, not more than from one to three leaf-buds should be left, and these should be immediately under the coming flower-bunches which they will serve to set off. A number of these leaf-buds on a flowering shoot would absorb a large proportion of sap, to the detriment of the flowers. All these preliminary operations having been carefully performed, the plants are next to be brought into the place where they are to be forced, great care being taken, in removing them, not to injure the flower-buds. When brought into the forcing-house, the plants are placed upright, with their naked roots on the floor (whether it be of earth, tiles, bricks or flags), and as close together as possible, so that the roots may overlap each other, and that a great number of plants may occupy a very small space. Where space is not an object, it is not absolutely indispensable that the plants should be placed so close together; nevertheless, this arrangement has one great advantage—viz., that, as the roots are quite uncovered (any soil placed over them would be fatal to the operation), the closer they are placed together, the denser is the network they form, and, in consequence, the more easily do they retain moisture. Another advantage of this close arrangement is that, the space to be heated being smaller, there is less loss of heat, which may then be more easily kept up, and at less expense. The plants being now placed in position, the stems and branches should be slightly watered, but not the terminal shoots. The house should be then closely shut up, and the glass covered in such a way as to completely exclude the light, so that the plants may be kept in continual darkness. Heating should then commence, the temperature being raised to 78° Fahr., at which it should be maintained night and day until the flowers are gathered. During the whole period of forcing, gentle waterings should be frequently given—several times a day, if necessary—in order to keep up a constant humidity in the atmosphere; and, when the flowers are coming into bud, arrangements must be made so as to introduce air without admitting any light, and without allowing the temperature to fall below 78° Fahr., this being absolutely necessary to success. All that now remains is the gathering of the flowers, which, as well as all other operations in the house, should be done by the light of a lantern, and this should be extinguished as soon as the work is over. In this way, and in this way only, is it possible to obtain the charming pure white Lilac as it is produced by the best Parisian growers. It is waste of time and labour to force the varieties of Lilac which have naturally white flowers, as they produce few flowers, and the bunches are small and unshapely. In order to have flowers to cut in succession throughout the winter, the operation of forcing should be repeated every eight or fifteen days, taking the number of plants required, and treating them as before directed, remembering that it takes from a month to six weeks' forcing to bring these shrubs into full flower. Plants destined for late forcings need not be removed from the nursery until September and October, but in all other respects they are to be treated in the same manner as those taken up in August. With respect to the plants which have been taken up, and await their turn for forcing, it will be well, in very frosty weather, to cover their roots with straw or leaves; but this will not be necessary, if, as we have directed, the plants have been placed at the north side of a wall, and sheltered from the sun. We may here remark that plants that have been once forced in this way become completely exhausted, and are afterwards good for nothing except to be used as fire-wood. Lastly, these plants should never be forced in a house, of which the frame-work is of iron, as the rusty drip from the roof is sure to fall on and spoil the flowers. There can be no doubt that the production of this charming winter-flower is as practicable here as in Paris; Mr. Howard, of Balham, succeeded in producing good samples last winter in a warm darkened shed. By following the directions previously given, very fine samples may be obtained. A portion of a low forcing-house, or deep pit, may conveniently be spared in most gardens where there is any extent of glass. In connection with this subject, it may be well again to call attention to the merits of the rather numerous varieties of the Lilac. They are great improvements on the type; and, when well-grown, most effective in the pleasure ground. The Lilac de Marly is one of the kinds alluded to.

W. M.

NOTES OF THE WEEK.

— At the International Botanical Congress, at Florence, we find that an additional grand medal has been voted to Messrs. Veitch & Sons, of Chelsea, whose specimens of *Nepenthes* were amongst the wonders of the exhibition. It is understood that they have been purchased by Count Casanuova, an eminent horticulturist, one of those Italian nobles, increasing in number every day, who devote themselves, with enlightened zeal, to the promotion of science in Italy.

— GOVERNMENT returns show that Ireland produced in 1873 2,683,060 tons of Potatoes. The acreage under this crop has been decreasing for the last two years; but the produce of 1873 showed a large increase over that of 1872.

— It may be of interest to plant growers to know that the "Davis competition plants" are to be shown next week (June 4th and 5th), at South Kensington, on the occasion of the great show which is to take place on these days.

— WE learn from the Italian papers that the attempts made last year in Italy, without success, to grow the Tea-plant, are being renewed in the Southern districts of Sicily. It is hoped that this attempt will prove successful, as special pains have been taken to procure seeds and plants from the best sources, direct from Japan.

— THAT interesting little annual festival, the "Flower Sermon," was preached the other evening in the Church of St. Catherine Cree, which was crowded, the greater part being young people, who, almost without exception, carried flowers in their hands. It is customary in these flower sermons to make the discourse turn upon some well-known plant or flower, and on the present occasion the words "Sweet Cinnamon" were chosen, a text from which the preacher drew a picture of the Cinnamon plant, and pointed out the lessons to be derived from it.

— Now, when the culture of hardy plants in pots is receiving the attention which it deserves, it may not be uninteresting to know that *Hyacinthus amethystinus* succeeds perfectly, when grown in this manner. Thus treated, plants of it grow strongly and bloom well, their lovely clusters of blue flowers having a charming effect. The pretty little *Iris cristata* also succeeds well in pots, a 24-sized potful of it, nicely in bloom, being one of the most attractive hardy plants shown at the recent exhibition at Manchester. Its flowers are of a delicate blue, the outer divisions being prettily streaked with orange.

— NEVER within our recollection has there been such a dearth of hardy herbaceous plants in bloom at the end of May as there is this year, a circumstance, doubtless, attributable to a very genial spring being succeeded by May weather, seldom or never equalled in severity. The following, among other plants, have been particularly affected by the weather, viz., *Iris* of different kinds, *Dicentra spectabilis* and *eximia*, *Corydalis lutea* and *Leucojum hyemale*. The foliage of *Funkias*, too, generally fine at this season, has suffered in a marked degree, an occurrence almost unprecedented. We have also noticed beds of *Lilium umbellatum* and its varieties, in which the flower-buds have been completely destroyed.

— PARTS of Great Cumberland Place and Oxford Street, near the Marble Arch, are now being subjected to a new system of watering by means of pipes, invented by Messrs. Brown, British River Irrigation Office, Edinburgh. The trial shows that the method is calculated to lay the dust perfectly with great economy of water, a remarkable saving in labour as compared with the water-cart system, and also with a saving in the wear of the road, both on granite and hard-faced macadamised street. With the pipe system the whole surface can be washed; or, for the purpose of laying dust only, a narrow strip next to each curb is watered in a few seconds. This arrests the whole of the deposits of dust, preventing them from rising in clouds; and the road being left for the most part dry, obviates both the creation of dust and the excessive wear of pavement occasioned by the common mode of watering twice every day.

— THE effects of the late frosts on market gardens are, we fear, worse in some localities than was at first anticipated; we shall, however, without doubt, have plenty of Apples, Pears, Plums, Cherries, Strawberries, and Gooseberries, although not that excessive abundance which the profusion of bloom at one time foreshadowed. Currants, in exposed situations, are much injured, two-thirds of the fruit having fallen; but under over-hanging trees the damage is not great. The earliest and finest blooms of Strawberries have also suffered, but still plenty has been left for a crop, which will be somewhat late, and its duration shorter than usual. Early Peas, such as Dillistone's Early, Dickson's First and Best, Sangster's No. 1, and other white round kinds that were so badly cut up when coming into bloom, will, in some cases, scarcely repay the trouble of

gathering. Late Marrows, however, look well and are likely to be abundant. Picking, generally, will now be from ten to fourteen days later than usual. Of Moss Roses, which are grown by the acre in market gardens, not a single sound bud, in some places, is to be found; every one, without exception, has been either partially destroyed, or has fallen off quite soft and black.

— ANOTHER edition of the Rev. S. Reynolds Hole's "Book about Roses" is in preparation; it will thus be seen that the book has met with the success which it deserved.

— THE first part of the third issue of Sowerby's "British Wild Flowers" (Van Voorst) is now out; the descriptions, with an Introduction and a Key to the Natural Orders, being by C. Pierpoint Johnson, Botanical Lecturer at Guy's Hospital.

— A CURIOUS little book has just been privately printed for Mr. William Bagge, of Shirle Hall, Sheffield, under the title of "Bibliotheca Nicotiana—a First Catalogue of Books about Tobacco." It comprises the title in full of about 170 separate works of various dates, from 1547 to the present time, upon the properties and uses of this popular herb. The collection of titles covers, in fact, with tolerable completeness, the special literature of tobacco since its original introduction into Europe.

— WE find that the fine plant of *Dendrobium Falconeri*, alluded to by us last week (see p. 432) was grown by Mr. J. Hill, gardener to Sir William Marriott, Down House, Blandford, and not by Mr. Hill, gardener at the Poles, Ware, as stated. A specimen of this *Dendrobe*, on a block, has, however, produced over 100 flowers at the Poles; and, since receiving Mr. Hill's letter, we have seen another fine specimen, which has from 200 to 300 buds, nearly open. As this plant, however, will shortly be exhibited, we shall again have an opportunity of alluding to it more fully.

— BLOOMS of the Cape Tulip (*T. Breyniana*) have been sent to us from Messrs. E. G. Henderson's nursery, in the Wellington Road. It is an old species, which bears small yellow, or rather orange, flowers tinged with reddish-brown, and delightfully sweet-scented. At Messrs. Osborn's it is grown in quantity under the Dutch name of *T. persica*, and elsewhere we have seen it labelled *T. Celsiana*. It seeds freely, produces offsets in abundance, and is well worth growing, if only for the sake of its fragrance, which, even in a cut state, it long retains.

— SOME of the Oxford undergraduates have taken up an idea of Mr. Ruskin's, not without interest to our readers. Mr. Ruskin deprecates the prevailing rage for athletics, chiefly on the ground that the results of such amusements as cricket, rowing, &c., are practically *nil*, excepting, of course, those produced on the individual athlete. He says, let us develop a new form of athletics, one which will leave some practical result, not only on the frames of the workers, but on the object of the work. It is for this purpose that a band of amateur gardeners has been formed, and the numbers who have joined are already so considerable that, whether for good or evil, this scheme will have a full and impartial trial. The place selected for the work is at Hincksey, about a mile from Oxford, and the ardour with which a number of undergraduates enter into the new scheme is a proof that Mr. Ruskin made a happy hit in suggesting this method of working off the superfluous physical energy of the University. The scheme has been ridiculed, of course, as was to be expected, but has been thus defended by Dr. Acland in the *Times*:—"Mr. Ruskin, a man of no narrow sympathies, has known Oxford for forty years. He is as interested in the greatness of the educated youth of England as he is in the well-doing of the poor. He is loved by both. To the high-spirited youth of Oxford he has said, 'Will none of you out of the abundance of your strength and of your leisure do anything for the poor? The poor ye have always with you. Drain a single cottage, repair a single village by-way, make good a single garden wall, make pleasant with flowers one widow's plot, and your muscles will be more strong and your hearts more light than had all your leisure hours been spent in costly games or yet more hurtful amusements.' Is he wrong? Are the hearty, kindly men who obeyed him, wrong? Are they likely to be worse Englishmen for their pleasant love of a respected teacher, and their cheery almost playful help to agricultural labourers? Will society be worse that a body of steady students, with a kindly enthusiasm, left their wonted games to lessen the sadness of the world, and make more bright some English cottage homes? To say nothing of the good of humane and hearty occupation to the men themselves, are we sure that sincere men such as these, when wisely directed, will not be among the best safeguards in the heaving, restless, social fabric of modern life. Is Mr. Ruskin impractical in thus harmlessly evoking the sympathies and energies of the unspoiled minds about him?" We may add that garden work, especially any kind of ground-work, is good exercise, inasmuch as a greater variety of muscles are brought into play than is the case in walking, and various other kinds of exercise in which one set only is employed.

GARDENING IN THE TIME OF PLINY.

Ancient Roman Villas.

THE shattered remnants of our castles and abbeys are, in many instances, more beautiful than the perfect structures ever could have been. When new, their bare cold stones, notwithstanding the carven traceries that enriched their mouldings, cornices, and windows must have been far less attractive, from a pictorial point of view, than their ruins are now—when wild and gracefully-straggling Bramble and brushwood have softened the asperities of their outlines, mantling Ivy robed their naked battlements, and the golden Wall-flower, crimson Antirrhinum, and wild Carnation crowned the broad broken ridges on which the prosaic roof once rested. Some of the Italian ruins, titanic remnants of Roman splendour are far more beautiful than any of our own; for, in addition to the grandeur of their dimensions, and the fascination of their greatly superior antiquity, the rich southern vegetation with which they are wreathed, as with funereal honours, invests them with a charm that northern climates cannot rival. Sebastiani, an Italian botanist, published an interesting account of all the plants found in the ruins of the Coliseum, which

he entitled "Flora Colisea," and enumerated 260 species. The author of "Childe Harold" pauses to describe the effect of that vegetation upon the hoary walls, as it appeared by night, alluding to the wreath of Bay or Laurel with which flatterers crowned Cæsar's portrait-statues, and even the profile which appears on his coinage. Our poet would have been deprived of the opportunity of making his allusion had his visit to Rome been made at the present time, for the city authorities, grown over active since their release from Papal thralldom, have cleared away the whole of the "Flora Colisea," and made it clean and tidy, in the same spirit that stimulated our British churchwardens to whitewash the interiors of so many of our fine parish churches, to make them neat.

The ruins of the villa of Hadrian, at Tivoli (the ancient Tibur), are among the most beautiful in the vicinity of Rome, partly in consequence of their site on the rugged western slope of the Sabine Hills, and partly in consequence of the more luxuriant vegetation, with which they are partially covered and surrounded, and in the midst of which dark spires of Cypresses are freely scattered, as shown in the accompanying engraving. It is possible that the architecture of this magnificent villa, which has proved a perfect mine of statues and other works of art, buried by continually falling ruins, was the design of Hadrian himself; as we know that several temples were built after his imperial devices, the non-observance of which, to the very letter, led to the "suppression," in the most fatal acceptance of the term, of the celebrated architect Apollodorus. The letters of a contemporary, Pliny the younger, afford a student the means of ascertaining pretty accurately what the character of those pleasant walks of the literary emperor were like; and a

few quotations from them will tend to prove that the Tiburian villa of Hadrian, and other villas of the ancient Romans, were very similar to those of the modern Italians.

Pliny possessed a villa at Tusculum (the modern Frascati), not far from that of Hadrian at Tibur; and he had also a marine villa at Laurentum, at one of the nearest points of the coast to the great city. He had also villas at Comum, the place of his birth (the modern Como), and in other parts of Italy, many of which he described with much minuteness in letters to his friends. Of the villa among the Appenines, close to the Larian Lake, now the Lago di Como, he gives, in a letter to his friend, Apollinaris, a very minute account, "The winters here," he says, "are severe and cold, so that Myrtles, Olives, and trees of that kind, which delight in constant warmth, will not flourish; but it produces Bay trees in abundance, though, indeed, they are sometimes killed to the ground by the frost. The summers, however, are exceedingly agreeable." Describing the view from the front of his villa, he says:—"The disposition of the country is the most beautiful that can be imagined. Figure to yourself an immense amphitheatre, such as Nature herself only can form. Before you lies a vast plain, bounded by mountains, whose summits are covered with venerable

woods." The lesser hills, he tells his friend, are as fertile as even the valleys, though they mature their crops somewhat later. "Below," he continues, "are numberless vineyards, which are terminated, as it were, by a border of shrubs; and lower are meadows and fertile fields." "You could not be better entertained," he exclaims, "than by a view from the top of one of our neighbouring mountains, which you might imagine not real, but some painted landscape, drawn with most exquisite beauty and exactness." It

Vegetation on a portion of the ruins of Hadrian's villa, at Tivoli.

is quite evident that Pliny had a keen taste for the beauties of unadorned Nature; though we shall see presently that he was a slave to the then prevailing fashion of gardening, in the principal features of which the Topiarius, or tree-clipper, played a very conspicuous part. "The aspect of the house is due south," he continues, "and seems to invite the afternoon sun into the spacious portico." "In front of the portico is an ambulatio (a kind of terrace walk), embellished with several statues, and bounded with a Box hedge, from which you descend by an easy slope, made agreeable to the eye by the representation of various animals in clipped Box . . . towards a lawn overspread by the soft—I had almost said liquid—Acanthus."* "This is surrounded by a walk, enclosed with suitable evergreens shaped into a variety of forms. Beyond it is a *gestatio*" (an arena for horse or carriage exercise) "laid out as a circus, ornamented in the central space by dwarf Box cut into numberless different kinds of figures; the whole being fenced in by a wall covered with clipped Box, rising by different ranges to the top. Beyond the wall lies a meadow that owes as many beauties to Nature as what I have been describing within owes to Art, and it is continued by other meadows and

* This name appears to have been given to some kind of Moss

fields interspersed with thickets." These last remarks are sufficient proof that Pliny admired Nature as well as Art in horticulture and arboriculture, and that something like our English park scenery, with trees unclipped, and interspersed with woods and thickets, generally formed a portion of the surroundings of a noble Roman's country seat. He next describes a "grand dining room" in a projecting portion of the building, which commands pleasing views of other parts of the structure, and also of the woods enclosing the Hippodrome. Also an adjacent apartment, consisting of three rooms in ordinary use, all of which "look out upon a small area softly shaded by four Plane trees, in the midst of which is a fountain, over the marble basin of which fresh spring water continually flows." There was also, it seems, another very snug room closely adjoining, which appears to have been a great favourite with Pliny. He tells his friend that it is "situated close to the nearest Plane tree, and enjoys a constant shade and verdure. Its interior," he says, "is lined half way up with carved marble;" and from thence to the ceiling, he informed his friend that foliage was painted, among which birds were seen perched upon the branches, which had an effect altogether as agreeable as the carving; while at the base, on one side, was a little fountain, ever playing, in several jets, into a graceful vase, "producing a most agreeable and soothing murmur." "Near at hand," he continues, "is an artificial cascade, which entertains at once both the eye and the ear." He next enumerates, in detail, the luxuries of the different bath-rooms, and the beauties of an elegant portico (colonnade) that connects the house with the Hippodrome. He then proceeds to dilate upon the charms of a grotto, with every accommodation for a pleasant summer retreat, *al fresco*, in which, he says, "during the summer heats pleasant coolness may always be enjoyed." In the annexed engraving it has been attempted to realise the probable aspect of Pliny's "cool and pleasant grotto." Just such a one, only more modest in extent and decoration, as was doubtless to be found in Hadrian's imperial villa at Tivoli; for such an adjunct was seldom absent from a Roman villa of any pretension. The woods seen through the entrance, shown in the illustration, may be supposed to be those enclosing the Hippodrome. Externally, the entrance presents the aspect of a rocky cave, softened in outline by closely-clinging Ivy; while the interior walls are formed of the imperishable Roman cement, decorated with fresco-painting, in designs similar to those of the Baths of Titus, which gave Raphael the first hint for his famous arabesques in the external galleries of the Vatican, and also by the presence of the never absent fountain. The ceiling is simply the naked rock, unadorned, except by a few climbing plants, that, with rambling grace, mock the unreality of the artificial foliage painted on the walls. The floor is, of course, of mosaic, and the marble table is spread with light refreshments, which may be awaiting the arrival of the host, with some select friend (the two seats are waiting for them) to discuss the merits of those poets of the day, long since forgotten, which it was the fashion of the time to consider superior to Homer and Virgil. Pliny tells us much more about his cherished villa—of apartments looking down the rocks to the Vineyards below—of an extra summer dining room, "cooled by the wholesome breezes which course through the Appenine valleys;" and he also tells his friend of a wood of "Plane trees covered with Ivy, so that while their heads flourish with their own foliage, their bodies enjoy a borrowed verdure, which spreads from tree to tree and connects them together." This plantation, his friend is told, formed "a straight boundary on either side of the Hippodrome, bending at the farther end into a semicircle, set round and sheltered with Cypresses, which cast a deeper and nobler shade." Within this plantation, and facing the course of the Hippodrome, there were seats for the comfort of spectators of the horse and chariot races; "and, behind them, among Bay and Box trees, were Roses that perfumed the air, making as pleasant a contrast to the dark foliage, as the coolness of the shade does with the warmth of the sun." He next speaks of another portion of the ground, concerning which he says to his friend Apollinaris (after describing plantations of fruit trees and hedges cropped into various devices), "On a sudden, after enjoying the effect of this elegant

regularity, you are surprised with an exact imitation of the negligent beauties of rural Nature," the character of which he proceeds to describe, along with an account of a marble alcove, with a fountain in the centre surrounded by a broad flat margin, which, being at a convenient distance from the encircling marble seat, was made to serve as a summer dining-table, the larger dishes being placed upon it, "while the smaller ones, in the form of aquatic birds, floated about upon the surface of the water." Opposite to this, as Apollinaris was told, was an exquisitely-sculptured marble summer-house, opening into a delightful green enclosure; and, annexed to this summer-house was a small room, "with windows on every side, which, nevertheless," he says, "enjoys a very soft and agreeable gloom, derived from trained Vines, which climb to the top, and entirely overshadow it." The self-satisfied Pliny closes his description (to us so charming and instructive, but which may have seemed somewhat prolix to his victimised correspondent) by reminding him that Homer employed many verses in the description of the arms of Achilles, as did also Virgil in that of Æneas; and he winds up by saying, that without such a minute description (of which our translation is but a mere sketch) he could not have fully explained why he preferred his villa at Comum to those which he possessed at Tusculum, Tibur, Præneste, and other places. Prosaic as his long account may have appeared to his friend, it has proved a most precious legacy to posterity, and enables us—while wandering through the beautiful ruins of Hadrian's villa in the midst of noble fragments of the past lying among Brambles—

Cypress and Ivy, weed and Wallflower grown,
Matted and massed together; hillocks heaped
On what were chambers, arch crushed, column strown
In fragments—choked vaults and frescoes steeped
In subterranean damps—

to realise, in imagination, the precise kind of characteristics which it presented in the palmy days of its newness and splendour. It has been remarked that the Roman gardens in the time of the Emperor Trajan bore a striking resemblance to French gardens of the seventeenth century in almost every particular of their arrangement.

THE LIBRARY.

THE AMATEUR'S ROSE BOOK.*

MR. SHIRLEY HIBBERD'S book—which is dedicated in a very genial and brotherly spirit to the Rev. S. Reynolds Hole, thus demonstrating that love among the Roses influences those who write about them, not with jealousy—green-eyed as a Rosa Gallica—but with pleasant fraternal sympathies—is well worthy of a perusal from all rosarians, but specially of those who, like the author, cultivate Roses close to cities and towns; but who, unlike the author, rarely realise even a resemblance of the royal flower. These desponding florists, however frequent and complete their disappointments may have been, should make this volume their own, not only by purchasing but by learning it; because he, who wrote, has proved that his instructions are no mere surmises and theories by producing at public exhibitions the Roses which he has grown. Therefore, "let the town amateur take courage," as Mr. Hibberd bids; "but let him also take care; for, to buy Roses hap-hazard, and plant them anyhow, will not answer in the furnishing of a town garden." Then follows advice, with the reason why it should be accepted, always simply and sensibly urged, as to size, situation, soil, planting, management, and selection of Roses most suitable for town gardens. But the townsman who loves Roses is wisely counselled by the author not to depend solely on the open ground for his supply, but to take advantage of the better climate, which may be secured by the employment of glass, and so, by good greenhouse culture, for which Mr. Hibberd gives ample and minute directions, to secure a plentiful bloom of those lovely Tea-scented Roses which he cannot grow in his garden. Here, again, we have the results of experience from the writer's own "Rose-house, at Stoke Newington," in lieu of mere speculations; and the reader is encouraged to trust his guide in the cheerful confidence that he knows the way, and that, if it be followed patiently, there is rest at the end of it—upon a bed of Roses. Many wood engravings teach the tyro far more quickly and accurately than words can, and there are some fine coloured plates of Roses, of which the best are Perle de Lyons and Maréchal Niel.

THE FRUIT GARDEN.

WIRING GARDEN WALLS.

I MUST beg to differ from Mr. Baines's estimate of this system, which I consider to be a great boon to gardeners and their employers, and we must not forget that we are indebted to you, Mr. Editor, for bringing the system into notice; for, although, as Mr. Baines says, it is an old system, yet it used to be very clumsily done. Now it is so simple and easy, and the little raidisseur, or tightener, works so well that any handy garden labourer can wire a wall without much trouble or expense. Of all the systems I have tried this is the best; it saves much labour, a point of great importance, for I know that there are hundreds of gardeners who have stood by walls nailing till they were almost frozen into an icicle. By the wiring system, and good bast ties, I will engage to tie a dozen branches while Mr. Baines is doing one by the old method. In many places the walls are all studded with nails, quincunx fashion, 9 inches apart; but even in that case it takes longer to tie a shoot to a nail than to wire, and then one has the branches farther from the wall than where wires are used. As to the shoots gumming, I have had less of that since I adopted this system than before; and as for crossing the tying material betwixt the shoot and the wire, I never think of giving more than one single twist round the wire to keep the shoot in its place. As regards the trees bulging out from the wall when old, I have some trees on the walls more than thirty years of age that have been wired, and, instead of old straggling spurs I have got them much closer to the wall than when the old system of nailing was practised. So far I can prove wiring to be a success. I have had upwards of 4,000 yards of galvanised wire put up on my walls five years ago, and each year I have had satisfactory crops of Peaches, Apricots, Figs, Pears, Plums, and Cherries. This spring, one or two Peach trees were not protected during the frosts which occurred in March; still, on those two we have a fair crop. Some of the Apricots, too, which had only a few Fir boughs tied to the wires to protect them, set their fruit quite thickly. I am quite sure that anyone who gives the wiring system a fair and impartial trial will be pleased with it. I find that three courses interval for Peaches, and four courses for Pears, answer very well.

H.

STRAWBERRY CULTURE.

MAKE the three following points a basis of operations, and Strawberry growing will be found to be a reality, viz., dig deeply, manure heavily, and plant early. The young runners should be layered about the middle of the month of June, in small pots filled with good sound loam. The pots should be placed under the runners, and a stone about the size of a small hen's egg should be laid on each runner. This keeps the soil damp, the pots steady, and the young plant in its place. When sufficient runners have been layered (which may be easily got at by measuring the land to be planted, allowing 3 feet from row to row, and $2\frac{1}{2}$ feet from plant to plant in the row), keep the young plants regularly watered daily, and, in about fifteen days, they will be rooted round the pots, and ready for planting, which should be done as follows:—Setting the line for the first row, take out holes, 9 inches in diameter and 6 inches deep, with the spade, and fill them with good loam and dung, planting the Strawberries firmly. By doing this you give the Strawberries a fair start. Afterwards give each a good watering, nicely level the soil about them, and the work of planting is completed. The system adopted by many is to plant Strawberries after Potatoes, in August and September, taking the runners from the old plants at random, and planting them with a dibber. Under such circumstances they look sorry things all the winter, and in the spring many deaths occur, making the Strawberry quarter look unsightly. The plants have little or no fruit the first year; whilst I maintain that if Strawberries are managed as directed, the first year's fruit is by a long way the best. Some say the quantity is not got thus, but what about the quality? Are not twelve Strawberries, weighing 10 oz., better than thirty weighing the same weight? The varieties which I have grown here consist of Sir Charles Napier,

British Queen, Keens's Seedling, Black Bess, and President. This season I am trying Laxton's Traveller, which has received a first-class certificate from the fruit committee of the Royal Horticultural Society. If I were asked the following question: Which is the best Strawberry? I should without hesitation answer, "Sir Charles Napier." This variety is hardy and prolific; it packs well, and carries its bloom, after being gathered, longer than any other variety with which I am acquainted. Variety is, however, not only pleasing, but fashionable; therefore, I grow Keens's Seedling for early work (Black Prince is earlier, but too small), Sir Charles Napier, Dr. Hogg, Black Bess, President, and British Queen; and, for the latest of all grown on north borders, Late Pine. Strawberry preserves are much in request here, and for that purpose I grow a pure, selected stock of Grove End Scarlet, which is prized more than any other variety for preserving. As regards productiveness, where large supplies are in demand, I may mention that on a yearling plant of Sir Charles Napier I have counted 374 expanded blooms, on Keens's Seedling 200, British Queen 150, and on Black Bess, a variety too little known, 234. Of the last I may mention that it was raised by a gentleman who never "let it out," but who gave a few special friends plants, my late employer being one of them. Black Bess is a mid-season variety, and a prodigious bearer, very dark in colour, sugary in flavour, refreshing, and in every way worthy of a place in first-class collections. I find that the best way of supplying Strawberries for my employer's table is to send in a different variety weekly, and to label all for the sake of comparison. This has a tendency to advance the interest taken in fruit culture. As to general cultivation, it consists in keeping the ground open and the weeds down. Watering is an operation which has not been performed here for these five years past. My practice is, when the Strawberry plants are in flower, to mulch them with long dung from the stables, for the purpose of keeping them damp and the fruit clean. When the fruit begins to colour I place stakes in rows over the quarter, tying rope yarn from stake to stake; and, over these, I place a net to keep off birds.

R. GILBERT.

PEACH TREES DROPPING THEIR BUDS.

THIS disease, if it may be called a disease, is so common now-a-days, and so disastrous to the Peach crop when it does occur, as to deserve some attention. Most gardeners are more or less acquainted with it from experience. In some cases, especially in that of early-forced trees, it is attended with the most ruinous consequences, every leaf-bud sometimes falling, except the terminal one on each shoot, making it very difficult to lay in a stock of bearing wood for the following year. The dropping always begins just when the buds begin to move. If the branches are tapped with the hand at this stage, they will fall off like a shower of hail; and, if the trees have been pruned on the cutting-back system, the chances are that no terminal bud will be left; and there is then no alternative but to cut all the previous year's growths back to their base, or out altogether if no buds are left, and trust to adventitious buds forming on the older wood. I have known cases quite as bad as this. Peach growers, therefore, who, like your correspondent, "Kent," in THE GARDEN the other day, are troubled with the disease, should never cut back the shoots at the winter pruning. I never knew the natural terminal bud to drop, even in the worst cases; but in shortened shoots—that is, shoots cut back to a leaf-bud—the leading bud is just as likely to fall as the others. It is a noticeable fact, that the disease has increased very much with the extension of Peach culture under glass. With Peaches out of doors it is seldom or never troublesome. Only under glass does it occur to a serious extent, and, the earlier the trees are forced, the worse it is; and here, I think, we have a clue to the cause. In an early Peach-house, for instance, when the fruit is ripe, in May or June, perhaps, and the wood and buds approaching maturity, the trees are naturally disposed to go to rest with a gradually decreasing temperature; but, though the matured foliage will fall off in due time, little or no diminution of temperature is experienced; and often, during August and September, the trees are exposed to a strong sun-heat, aggravated by the protection of glass, which forces the buds into a partial activity at the wrong time. By

October the cold weather sets in, and the trees are again brought to a sudden standstill till December or January, when they are started in the usual course; but, no sooner do the prematurely forward buds feel the stimulus than they drop off—as the fruit would certainly do at the stoning period, under similar conditions. Whether this explanation is correct or not, I have described exactly what happens, at least under the circumstances, and I can further add, that when means are taken to save the trees from being prematurely excited, by removing the lights in summer and autumn, or shading, &c., the evil disappears, or nearly so. Nine years ago we planted an early Peach-house here, and for a few years after planting the buds dropped, more or less, when the trees were started, but more especially after hot summers and autumns like 1868. At such times, I have seen the thermometer in this house stand at 90° and 95°, day after day, in spite of ample ventilation, when the trees were leafless, and should have been at complete rest. Feeling, in my own mind, sure that this was the cause of the buds dropping, I made arrangements for having the roof sashes, which were fixtures, removed entirely after the fruit was gathered in June, which practice I have adhered to for the last five or six years, and the dropping has entirely ceased from that time. If a few buds do fall off occasionally, they are so few as not to attract attention. In late houses dropping does occur, but to a less serious extent. In such cases the remedy is to keep the houses as cool and airy as possible after the wood is ripe and the leaves begin to change colour—if possible keep the trees at complete rest till they start in spring. Where this practice is adopted, bud dropping will cease to be troublesome. Dryness at the root, and want of attention otherwise, may probably accelerate the disease; but I have seen the most healthy trees, in every respect, drop their buds under the circumstances described, where both border and roots were in the most healthy condition, and where the trees received every attention. Besides the case I have recorded, many instances have come under my notice from time to time, and I have always had good reason to suppose that the evil was due to the causes I have mentioned. J. S. W.

Watering Pines.—"That many Pines are over-watered," says Mr. Muir (see p. 440), cannot be contraverted; and, considering the number of Pine growers that exist in the country, we may, I think, admit the possibility of accidents and mistakes in this as in other things, and possibly, also, the counter proposition that "many Pines are under-watered" may be propounded with equal safety. Again, Mr. Muir remarks that "fruits of all kinds, Pines not excepted, ripened and gathered from plants that are living in a semi-aquatic state, are always very much inferior in flavour to those ripened under more genial conditions." In his experience as regards this matter Mr. Muir stands quite alone, though I should imagine he is perfectly right. Hitherto, I have not seen Grapes, Peaches, or Pines grown in water. Next, he reverts to the Glasgow show, at which I neither exhibited nor visited; and what that exhibition has to do with the subject under discussion I cannot imagine, but as he seems anxious to quote the opinion of the editor of *The Gardener* in such matters, I may inform him that Mr. Thomson called here a few days before the Nottingham show, on his tour southwards, and saw our Pines, and he afterwards told me that they were amongst the best he had seen on his journey; and in the brief report of that exhibition, which was given in *The Gardener*, the fruit, generally, is described as being somewhat ordinary, Pines excepted. As to my Pines at last year's Manchester show, the few which I exhibited in my collection were the tail end of the summer fruit, and had been kept five weeks in the fruit-room; consequently, the crowns were somewhat shrivelled, but, otherwise, the fruits, which varied from 3 lbs. to 4 lbs. weight each, were, when cut up, sound and excellent, even after having been kept so long. They were mostly smooth-leaved Cayennes, and, had it not been for these considerations I should, probably, have entered in the single class for Pines which I did not do. My object in stating my success was to corroborate my practice, and I would remind your correspondent that, before he proceeds to diminish the value of other people's evidence, he should furnish some of his own, in support of what are, as yet, apparently only assertions.—J. SIMPSON.

Early White Grapes.—The earliest variety in ripening with me is the Early Malvasia, or Early Keinzheim of the Horticultural Society; it is a luscious, sweet, little white Grape, which ripens in the end of August, followed by other early white sorts, such as Early Malingre, Early Smyrna Frontignan, Chasselas Vibert, Early Saumur Frontignan, and Royal Muscadine or Chasselas de Fontainebleau of the French.—W. T.

THE FLOWER GARDEN.

CULTURE OF THE VIOLET FOR THE PARIS MARKET.

THOSE who purchase or are presented with bouquets of Violets, have, as a rule, little idea of the labour and attention required to produce this pretty little flower and prepare it for market. They think, probably, that the woods, hedges, and meadows, furnish the immense quantities of it which are seen in Paris in the early spring, and in smaller or larger quantities throughout the summer, autumn, and even winter, according to the coolness or mildness of the three last-named seasons; whence the plant has been named "*Violette des Quatre Saisons*." It is a variety of the Wild Sweet Violet (*Viola odorata*), that may have been a wild seedling sown naturally, or it may have sprung from seed gathered and sown by some cultivator intent on raising varieties. However that may be, the variety is not very well fixed, as in some cases it produces plants which vary a good deal. The plants which unite all these qualities in greatest perfection are, of course, preferred by the growers. The Sweet Violet has also produced several other varieties, such as the Single White, the Double White, the Single Rose, the Double Rose, the Double Violet or Blue, and the variety named *Violette de Parme*. This last, which differs from the Sweet Violet in having smaller and paler leaves, and large, long-stalked, very double flowers of a pale or delicate blue colour mixed with a little white at the base, and with a stronger odour, which is different from that of other Violets, is, nevertheless, considered to be nothing but a variety of the same plant. It is almost the only variety which is grown for forming bouquets along with the *Violette des Quatre Saisons*.

Cultivation of the Sweet Violet.

This charming flower is cultivated on a large scale in certain parts of the environs of Paris, often close to the Strawberry fields, and in March, when it is in full bloom, forms wide sheets of blue. It grows well in almost any kind of soil, but does best in that which is neither too dry nor too moist, and which is either flinty, sandy, or calcareous; or, better still, composed of all three. The sand especially keeps the soil slightly moist and cool during the summer, and helps to drain it in the winter. Moreover, if these plants are grown with a view to sale, it is best to choose, as much as possible, a position sheltered from the north and west, and sloping towards the south, as, under such conditions, the plants will flower better at the close of the autumn, and also in winter—two seasons when the flowers bring the highest prices. Before planting, the soil should be well stirred up with the spade or hoe, and, although the roots of the Violet do not descend very deep, the plants will grow so much the better and more vigorously, in proportion as the soil has been well stirred up. The large lumps or clods should then be broken and pulverised as much as possible with a long-toothed iron rake or with a fork. The ground having been thus prepared, lines or drills should be marked out, at a distance of 1 foot from each other, and the plants should be set at about the same distance from each other in the rows. Every four rows should form a bed, so that the flowers of two rows may be gathered from the alley on each side without trampling on the soil of the bed, or the plants themselves. These alleys should be about 20 inches wide. The plants are chosen from the strongest runners which the largest plants produce in quantities, like Strawberries, or these large plants themselves may be divided, providing they are not too old or worn out. The plants are usually inserted in the rows with the help of a dibber. The most favourable season for planting is in spring, when the greater part of the flowering is over, that is, in March or early in April. It may also be done late in summer or early in autumn, but, in cold or damp soils, young plants put in at that time are apt to suffer when the winter is severe, as they have not had time to become well-rooted; and as, in this case, it often happens that they will not flower sufficiently during the following winter and spring to be of any great value, it is a loss instead of a gain to plant them late in the year. The best kind of manure to employ, especially in rather cold soils, is street-scrappings, which are a mixture of rubbish of all kinds, and are the manure almost exclusively used by Violet-growers and Strawberry-growers in the neighbourhood of Paris. In autumn, when the ground is being dug and prepared, this manure is dug in, or sometimes it is merely spread on the surface around the plants. It possesses very active properties, and always promotes active growth. The Violet, like all other spreading plants, reproduces itself from runners, which, issuing from the parent plant, tend to exhaust it early. In the wild state this is always the case, but, under cultivation, the various operations of hoeing, manuring, &c., necessitate the removal of the runners every year, at the end of summer or early in autumn. Notwithstanding this, they continue to be produced, to the exhaustion of the old plants, an exhaustion which is also hastened by the continuous flowering of the plants during nearly the whole year; so that

in the third year after planting, the flowers become less abundant, smaller in size, and on shorter stalks. It is therefore advisable, after the third year, to pull up the old plants and make a fresh plantation of young ones.

Forcing.

In forcing them diverse processes are employed, according to the season at which they are required to flower, as well as to the practice of different cultivators. In the first place, there is the system of cool forcing under frames, which is carried out in two ways. The first of these consists in planting in a well-drained light soil, and, if possible, on ground sloping to the south, or under the shelter of a south wall, either runners or divisions of old plants, six or seven inches asunder, in beds of a size proportionate to the width of the frames. This should be done in March and April; and, if divisions of plants are used, these should be taken from plants that have not been forced the year before. After the plants are set, a mulching of street-scrapings should be spread over the soil around them. This serves both as a manure and as a protection. If street-scrapings cannot be had,

mats. The frames also should be surrounded with warm manure, or leaves, for the same purpose of keeping out the frost. When treated in this way, the plants will afford a succession of flowers up to February, and, if the mats have been kept on, they will flower still longer. The flowers are usually gathered three times a week, when the plants are in full bloom; after that, twice and once a week. According to the size of the lights, the plants will yield from four to six bouquets to each light, which, at New Year's Day, sometimes sell for 5 francs (4s. 2d.) each. The expense of culture consists, in the first place, of the purchase of the plants, which amounts to from 5 to 6 francs (4s. 2d. to 5s.) per 100; to this must be added the cost of planting, watering, gathering, packing, &c., and the interest on the cost of the frames and mats. Taken altogether, the profit on each frame used in forcing Violets, in this "cool" way, amounts to from 2s. 6d. to 4s. 4d. Violets are also forced in heat, either on a hot-bed or with the assistance of hot-water pipes, and, sometimes, both are employed together. This method is generally resorted to when a good supply of flowers is desired about New Year's Day. The details of the process are these:—In the beginning of December,

A Grotto in the garden of a Roman villa of the time of Hadrian (see page 456).

then use short stable-manure or spent hot-bed dung. Water must be given during hot weather. The plants will commence to flower in September. When they have become pretty well hardened, which will be in the course of October, the frames and lights must be put over them for protection, and in such a position that the glass will not be more than 6 inches above the leaves of the plants. Air should then be given, in proportion as it is desired to hasten or retard the flowering of the plants, which generally lasts until December or January. The second mode of forcing consists in taking up, with a ball, plants which have been put out in open air in January or February of the same year, and transplanting them at once into frames. If the plants are required to flower soon, mats should be placed over the frames; otherwise, they need not be put on until November. Air should be given until they have rooted well; but then, and afterwards, unless the weather is fine, little air should be given, as it is not the air, but the sunlight on the frames which causes the plants to flower. But, if the weather is moist, without frost, a little air should be given, to counteract the humidity; and, when the nights are cold and frosty, the frames should be covered with

thick hot-beds are made, the best of which are composed of half new stable-manure and half of leaves; both should be well mixed together before the bed is finally completed. The *raison d'être* of the leaves is this, that, at first, they hinder the manure from heating too fast, and afterwards that they retain and prolong the heat. On these beds the frames are placed, and some good soil is spread over them sufficiently deep to allow of the plants being inserted. These should be chosen from those plants which have the best-developed and most numerous flower-buds. They should always be lifted with a good ball. The hot-beds should be surrounded with fresh stable-dung, and, during the night, the frames should be covered with mats or some other protection. Very little air should be given, and only occasionally in the middle of the day, as soon as the bed begins to heat, and provided there is not much either of frost or of north-east winds. The plants should be looked after, from time to time, in order to give them such a supply of air as will either advance or retard them, so that they may come into bloom at the desired time. In forcing Violets by means of hot-water pipes, the same rules prevail which we have indicated for the process of

forcing in hot-beds. There is this exception, however, that plants forced in hot-beds flower earlier and more regularly, because the heat is uniform and underneath. When hot-water pipes are employed, no matter what care may be taken, vicissitudes of temperature will occur, especially at night. When the plants are grown under frames, in which the air is more or less confined, mildew will often occur amongst them, and care must be taken to look them over frequently, and remove all leaves that show any sign of this enemy.

Snails and Slugs.

These frequently attack the flowers of the Violet. The best remedy for them is to place among the plants leaves of Lettuce or Cabbage. [The latter, if anointed with lard, will be found the best trap. Ed.] In the morning these can be taken up and thrown into hot water. At night-time, if one wishes to go round the frames with a lantern, the marauders may be detected in the act, and a sprinkling of a pinch of guano over them will put a stop to any further annoyance from them.

Culture of the Neapolitan Violet.

The "Violette de Parme" is seldom grown about Paris, because it is more tender than the *Violette des Quatre Saisons*. It often rots off and gets frozen during winter. Nevertheless, many growers plant it in beds in gardens, in well-sheltered positions, where the soil is well drained. They are also careful to cover it with frames before the frosts come on, for it does not do to plant it out, and then cover it with mats. If this is done, the flowers hardly ever come to anything; and the only time when this transplanting can be done with success is when the plants are showing buds, and even then care must be taken to remove them with good balls. When they are placed under frames, the same treatment which has been described for the *Violette des Quatre Saisons* is applicable to them also. The only advantage which the *Violette de Parme* possesses over the last-named plant is that it flowers later—generally until May. It always sells for a higher price than the *Violette des Quatre Saisons*. It has many sub-varieties, of which market growers give the preference to those which are most floriferous, and which have the deepest-coloured flowers. It may be easily seen, from what has been related, that the culture of the Violet requires more attention than is generally supposed, and that it is not only costly, because it demands much care and attention even when it does succeed, but that it is, in bad seasons, not much of a gain, if not a positive loss.

Profits of Violet Growing.

It is difficult to calculate accurately the probable produce of a crop of Violets, as it is exceedingly variable. In one season 12,000 bouquets may be gathered from $2\frac{1}{2}$ acres of ground, while, in another season, the same ground may not yield more than 3,000 bouquets. But, usually, the profit is greater when the general crop is moderate, as, when the general crop is abundant, prices fall very low in the market, and sometimes hardly more than repay the various expenses of culture, rent of ground, &c. This will be made plainer from the following calculations on the produce of $2\frac{1}{2}$ acres, during three seasons of maximum, medium, and minimum produce. In a year of plenty (say 12,000 bouquets to $2\frac{1}{2}$ acres), the first bouquets of winter and the latest in autumn will fetch about 5d. a piece, and, when the full crop comes in in spring, 1d. a piece. Supposing one-half the crop sells at the first price, and the other half at the second, we have—

12,000 bouquets @ 3d. each £150

Against this we must set off the expenses as follows:—

	£	s.	d.
Rent of $2\frac{1}{2}$ acres of ground	12	0	0
Digging and preparing the soil	4	0	0
Three hoeings at £2 8s. 4d. each	7	5	0
Manure	14	8	4
Spreading the manure	1	5	2
Cutting off the runners	0	16	8
Gathering, packing, and other market expenses of 12,000 bouquets at 1d. each	50	0	0
Total	£89	15	2

Deducting this from £150 0 0
89 15 2

We have a profit of £60 4 10

If, now, we take a season with a medium crop (say 6,000 bouquets to $2\frac{1}{2}$ acres), these will sell for 2d. each at the lowest price and for 10d. each at the highest, or 3,000 at 2d. each and 3,000 at 10d. each—£140. The expenses will be the same as in the last case, except for the gathering, packing, and other market expenses, which for 6,000 bouquets at 1d. each will be £25, instead of £50. Deducting this from £89 15s. 2d. we have £64 15s. 2d., which, deducted from £140,

the market value of 6,000 bouquets, leaves a profit of £75 4s. 10d. Lastly, let us take a season with a minimum crop of, say, about 3,000 bouquets to $2\frac{1}{2}$ acres, of which 1,500 will fetch 1s. 0½d. each (or £78 2s. 6d.), and 1,500 will sell for 4d. each (or £25), equal in the total to £103 2s. 6d. The general expenses will be still the same, except in the matter of gathering, packing, &c., which for 3,000 bouquets at 1d. each, will amount to £12 10s. To this must be added the other expenses, which, as before, amount to £39 15s. 2d., making a total of £52 5s. 2d. Deducting this from £103 2s. 6d. (the market value of the 3,000 bouquets) we have a profit of £50 17s. 4d. From the foregoing calculations (taken from the *Revue Horticole*, from which this article is translated), it will be seen that the profit is greatest in seasons of medium produce, since, in years of maximum yield, the various expenses of gathering, packing, &c., are much increased, while the market price is diminished to the lowest, indeed sometimes so much that growers do not care to gather their flowers. On the other hand, in seasons of minimum produce, it is the other general expenses, which, remaining, as they do, unchanged, swallow up the greater part of the profits. It must be understood, however, that the figures given here are only approximative, and that in the previous calculations, we have inadvertently omitted the cost of planting, which for the hectare ($2\frac{1}{2}$ acres) amounts to £2 10s. This must be added to the expense side of the account. W. M.

THE AURICULA.

THIS is by no means a tender plant, or one at all fearful of the cold blasts of chill winter; naturally it has a robust constitution, preferring an open, but dry, spot to one more sheltered and damp. In fact, the whole race of Alpine Auriculas does best when grown under conditions somewhat similar to those usually applied to ordinary Alpine plants; although these Auriculas have, of late years, been elevated to the rank of florists' flowers. I have now in my memory the experience of an old friend, a dock clerk, who suddenly became fond of Auriculas through seeing them grown by a friend. He purchased a few plants for himself, had a few given him, and got some seed, which he sowed, raised a batch of seedlings, and thus found himself fairly started as an Auricula grower. From a few indifferent plants, with the properties of which he was comparatively unacquainted, his collection soon increased to a hundred or more, besides a fine batch of seedlings. He then obtained a few useful frames with glass-lights and trellised bottoms; and now he has added some of the best show and fancy Auriculas that are within the reach of his purse. Now here is an example which those whose vocation is of a sedentary character might well follow; and there are hundreds—aye, thousands—similarly circumstanced, who have nice little gardens, and plenty of room to carry on such work. Verily, there is more pleasure, profit, and instruction to be derived from the working of a garden, however small, by oneself, than is dreamt of by ninety-nine out of every hundred persons. To those who love gardening for its own sake, the Auricula and its cultivation offers a special attraction. Technically, the Auricula is divided into two classes, viz., the show kinds and the Alpine or fancy sorts. The first are the more expensive and less easily cultivated varieties; the latter are emphatically everybody's flowers, but they depend for their beauty very largely upon the attention and selection which they receive under cultivation. I should earnestly advise all intending growers of this flower to content themselves with the Alpine class to start with; and then, when they have acquired knowledge, learnt from experience, they may safely invest in the choicer forms of the show kinds—those singular but beautiful white, grey, and green-edged flowers, with curious markings, beautifully-defined centres, and incrustations of so-called paste. These show kinds, also, have some splendid self-coloured forms, that is, flowers in which the centre is clearly and distinctly belted with some rich hue of colour, and in which there is no edging. These are invariably striking flowers in a collection, because of the preponderance of edged kinds, nearly all of which present a light appearance. In the Alpine class, on the other hand, dark colours preponderate, that is, if the strain be good; but some strains, remarkable for coarse growth and large trusses, commonly yield flowers of diversified hues, conspicuous amongst which are buffs, browns, and other objectionable colours. These may be pretty enough in ordinary borders, but are not worth special attention.

Alpine Auriculas are, after all, the most acceptable to amateurs, and especially, as I have said, to beginners; they are cheaper, hardier, and more easily cultivated than the other kinds; indeed, they thrive well in ordinary garden soil without special care or attention, but if they are grown for purposes of exhibition, then shelter and good cultivation must be afforded them. The stock-in-trade, so to speak of an amateur Auricula grower, need not be extensive or expensive, say a couple of dozen plants to start with, one-half of which should be good and of a fair price; the other half second-rate, and, consequently, cheaper; then a "cast" each of large 60 and 48-sized pots will be stock of pottery enough for a long time. A barrowful of good compost, consisting of two-thirds yellow loam from a rich pasture, and the remaining third, well-rotted manure and silver-sand will be sufficient potting material for a twelvemonth at least. For housing the plants, a stout frame about 3 feet in width and 4 feet in depth will afford abundant space for a year or two, but if the stock be rapidly increased more room must be added. In the bottom of the frame should be either several inches of clean shingle, or, what is better, a moveable trellis, which could be raised or lowered as desired. By this means air can be made to circulate around the pots as freely as about the plants. Damp at any season is detrimental, but especially so at the blooming period, and if the frame be placed upon a few bricks, so that air may be admitted freely beneath, and plenty of air be given at the top, any mishap from that cause can scarcely occur.

Seeds may be sown as soon as ripe, but it will be useless to look for bloom from seedlings the next spring; these will, however, make strong plants for the following season, and be all the more satisfactory for the few additional month's growth they have had. Yearling plants, of the coarser kinds, will often produce good heads of bloom, but the best kinds, having a more refined habit, are of slower growth, and, in consequence, seldom bloom until the second year. If seed be sown in July, when just gathered, and it germinates freely, the seedlings should be large enough to prick out into pans or shallow boxes for the winter, and the next spring they may be potted into sixties, in which all but the very largest may flower the ensuing season, the others being shifted during the autumn into 48-sized pots. They will need but a moderate amount of water during winter; but, as blooms are thrown up, more water will be desirable. The frame should be placed under a north wall during summer, and shading should be given when sunshine is powerful.

ALEX. DEAN.

Bedfont.

EAST LOTHIAN INTERMEDIATE STOCKS.

THESE Stocks merit a fuller notice than the brief allusion to them at p. 391 of THE GARDEN. There are three distinct varieties of them—a deep purple, a pure white, and a bright scarlet; and so very distinct are these colours, that they are vividly conspicuous, even beside other plants having flowers possessing similar colours. When planted in beds by themselves, forming centres to other outlying colours, or in ribbon borders, their effect is simply magnificent. Nor are they suitable for association with Geraniums, and other summer bedding plants, alone; they are equally well fitted for planting in herbaceous borders. They grow rapidly, and flower abundantly. I have seen plants of them, put out in May, each produce two dozen full-bloomed flower-stems by August, their great Hyacinth-like spikes, of different heights, standing out in gorgeous relief against flat masses of colour. The worst feature about German Stocks raised from Continental saved seeds is, they cannot be depended on to produce definite colours; and, therefore, cannot be planted in the flower garden with any certainty that they will properly harmonise with other colours. In East Lothian, near the coast, the Stocks under notice are finely in bloom from July until February. Here, pretty far inland, they remain in tolerably good condition well into January, thus forming a link between summer and spring flowers. This variety of Stock was raised by a Mr. Campbell, near Drem, in East Lothian; and we are indebted to Mr. David Thomson for showing us how well suited it is for flower garden decoration. This he did at

Dirleton, and the rows of it, in the fine ribbon borders which he had at Archerfield, were well worth travelling miles to see. The flower-spikes of this Stock, which may be had in armfuls at Christmas from outside borders, are excellent for floral decorations of a sacred kind. Crosses and other symbolic devices may be made with them; such devices, generally on strips of zinc 2 inches wide, are edged with a single row of Holly leaves, the centres being filled with Stock blooms. The dark shining green leaves of such Hollies as *Ilex Aquifolium*, make a fine edge when the centre is white, and the light-coloured foliage of the Silver Queen *Ilex* makes a pretty and becoming edge for deep purple. In order to attach the blooms to the zinc a little glue should be rubbed on it, a plan by which the flowers can be secured as desired. Care should, however, be taken to obtain the East Lothian Stocks true to name, as other kinds are often substituted for them. J. MUIR.

BEDDING PLANTS.

THOSE among us who are old enough to have witnessed the various phases through which the bedding system has passed will, I think, admit that, although in its present development it may have lost some of its rougher, perhaps more striking, elements of beauty in the banishment of such plants as Hollyhocks and Dahlias from the flower garden, it has gained in refinement by the introduction of beauty of form, in the shape of fine-leaved plants and plants of stately growth. What is called carpet-bedding, too, gives an additional and pleasing variety to our flower gardens, and in storm or in sunshine, unlike many beds of flowering plants, its effect is constant; and, as many of the plants adapted for it are hardy, it will, I think, continue to grow in favour. The mixed system of bedding has many advocates, and, whilst agreeing in the main with a good deal that has been advanced in its favour, I must say that for large gardens, grand masses of colour at certain points are a necessity; to fritter away all the beds in mixtures, however pleasing in themselves would be monotonous. Although I look upon the bedding system as a grand means of throwing masses of floral beauty round particular spots from June till October, in a way that cannot be equalled by anything else (if we except, perhaps, Rhododendrons in spring), I see no reason why every nook and corner should be devoted to it, to the exclusion of all other modes of ornamentation. To a lover of flowers, in the true sense of the word, the Alpine garden is unsurpassed in interest and in its capability to give real pleasure at all seasons. A vivid recollection arises in my mind of an Alpine or rock garden, with which I was once intimately acquainted, I could go blindfold and find the rocky nooks where flourished the Dog's Tooth Violet, *Erinus alpinus*, *Iris reticulata*, and many other floral gems. A little more than a year ago I again saw this same garden, but death had been busy amongst its rulers, and the garden had suffered in consequence; the strong-growing species had destroyed their weaker and rarer brethren, and what was once a good collection of plants is reduced to a few common strong-growing kinds. I mention this to show that weakly-growing rare species should not be planted in the immediate neighbourhood of strong-growing common plants, unless a constant watchfulness can be exercised over them; and it is a good plan also to keep duplicates of the choicest species in pots plunged in ashes, where they can easily be attended to. What I chiefly regret in connection with the bedding system is the destruction which it has entailed upon many beautiful old-fashioned flowers. There are, however, symptoms that extreme colourists are seeing the advantage of toning down their reds with flowers less conspicuous in tint. Amongst recent introductions for bedding purposes few are more useful than Violets and Pansies. A continuation of damp weather does not destroy their brightness; they are, in fact, weather-proof. Most of them, in addition to being valuable summer bedding-plants, are especially useful for spring blooming, and they are as hardy as the common Daisy; but they should be propagated annually either by means of seeds or cuttings. Although the seedlings may vary a shade or two in colour, most of them will come true enough for all practical purposes. I do not find that they are at all particular as to soil, provided there is depth enough. They are in this respect much more manageable than the ordinary florist's Pansies. They involve no costly fire heat or trouble in potting; in fact, thousands of them are coming up from self-sown seeds last year in the beds in which they grew. During the last few years *Calceolarias* have in many places done badly, and it is hardly to be wondered at, if they are grown year after year in the same beds without change of soil. Rotation of cropping is as important in the flower-garden as in the vegetable department; and especially is this necessary where the supply of manure is short. Deep cultivation and occasional partial

renewing of the soil, with annual dressings of manure or charred refuse, are important aids to success. In one or two instances that have come under my notice, retaining the spring flowers in the beds till they were required for the summer occupants has had a bad effect upon the summer display. To carry on spring and summer gardening in the same bed involves a large outlay, if both are to be well done; and, unless it is convenient to manure heavily, and to partially renew the soil at rather frequent intervals, it is better to be content with only a few of the beds filled with bulbs and other spring-flowering plants, changing them annually, whilst the others could be filled with cuttings of evergreens that would not exhaust the soil. Where cuttings of the golden Willow and the red Dogwood can be obtained in quantity, they have a not unpleasing effect in close dwarf masses in association with the different kinds of evergreens, and they would retain their freshness well up into the spring, which the evergreens would scarcely do unless changed.

E. HOBDAV.

Good Kinds of Wallflowers.—In the list of Single Wallflowers (see p. 390) I see no notice of a very dark variety, spikes of which I send you, but not the best, which are for seed. It is the only single Wallflower which I grow, and, in consequence, I have kept it true for above fifty years. I must own, however, that common streaked yellow and brown, or the wild dwarf sort of Wallflowers, have much more perfume than this dark kind; nevertheless our garden is well perfumed by it. We have lost a double dark variety, as black as our darkest single, which I got long ago at Penshurst (Porter's Lodge), and remember, about Tunbridge there was a very good double variety in all the little gardens, not so black as the Penshurst one. The small double-yellow (of which I also send blooms) flowers for ten months; it expanded the first week of February this winter, and is invaluable. We got it from Mr. Harpur Crewe.—F. J. HOPE, *Wardie Lodge*.—[The dark Wallflower, here described, is almost black, and large and fine. The yellow kind was not a close-spiked variety, but the flowers, individually, were quite double, and handsome.—ED.]

The Butterwort (Pinguicula.)—I had often seen, and greatly admired, this exquisite little plant growing in its native habitats amongst the mountains, and as often tried to grow it, without success, until I imitated exactly the natural conditions required for its culture. The year before last I came across a quantity of it, some of which I brought home along with a portion of the soil in which it grew, and then planted it in a large pot which I placed in water in a cool greenhouse. It flourished admirably under this treatment, and is now a perfect picture, the beautiful dark-purple flowers, larger and more graceful than any Violet, rising from each rosette of pale green leaves, which lie perfectly flat upon the earth. Some of the plants, which have now as many as eight blossoms expanded and in the bud state, are extremely pretty. Its mode of self-propagation struck me as very curious, each large plant, when the season's leaves die off, appearing thickly surrounded with numerous small offsets which the parent plant seems to have the power of scattering to some distance, as I have frequently seen them lying on their sides, an inch away from their birthplace, in which position they take root and form separate plants in a little time. It is not, however, till the third year that they make any display, but they are well worth waiting for, and I strongly recommend all lovers of uncommon plants to give the Butterwort a trial, particularly those who possess that interesting thing—a bog garden. I should mention that I found it growing last time in a kind of loam, but think an admixture of peat is most beneficial. It should not be allowed to get dry, but this is easily prevented, as, the saucer in which the pot stands being once filled with water, will not require replenishing afterwards for several days.—H. S.

Iris stylosa.—This pretty winter-blooming hardy Iris, the name of which appeared not long since in some of our catalogues as a novelty, was described six years ago by M. Clemenceau, in the *Revue Horticole*, as follows:—"The flowers, which continue from December until March or April, are of a handsome azure-blue, on stalks from 6 to 8 inches high, springing from the centre of a tuft of glaucous, narrow, and sword-shaped leaves. The tuft is generally of pretty large size, especially if it has not been taken up and divided for some years. The limb of the petals is of about the same size as in the dwarf Irises of our gardens, but is elevated on the summit of a tube about 4 inches long, which looks as if it were the peduncle of the flower. In addition to beauty of colour and singularity of form, the flowers also exhale a most agreeable scent, and are produced in succession for the space of two or three months. The plant does best in sweet, well-drained, light soil, and should be placed in a sheltered position, if possible. If it is desired to enjoy to the utmost the delicate tints and fragrance of this fine species, a light covering or shelter of some kind should be placed over it so as to protect it

from heavy driving rains, snow, and hard frosts, which are always more or less injurious to the delicate tissues of flowers, even those of the hardiest plants. It is propagated by division of the tufts, the best time for performing which is in spring, immediately after the plant has done flowering. When grown in pots, it forms an excellent room plant or subject for the conservatory or winter garden.

Primula altaica.—I believe that I have at length succeeded in securing this really pretty, but scarce, plant, and I find that it is quite different from the *P. altaica* that has been grown and exhibited for the past year or two. Not long ago Mr. James Backhouse, of York, stated that the lilac Primrose, shown as *Altaica*, was but a single form of the old double lilac, a statement, however, with which I disagree, so far as relates to the single lilac, pin-eyed form, being a sport from the double, as I have in *Lilacina* a true sport from the double lilac, and it is altogether a different and much more beautiful plant than what has hitherto been thought to be *Altaica*. I think that the lilac, so called *Altaica*, is an imported variety that has been misnamed. It is very early, and in spite of the flowers being rough, uneven, and pin-eyed, it is, nevertheless, a delightful denizen of the Alpine garden. In consequence of my notes on Primroses having appeared in *THE GARDEN* a few weeks ago, I have had several communications from a clergyman in the north, who is an enthusiastic collector of hardy plants, and he has very kindly favoured me with a plant of the true *Altaica*, and I find that, in all respects except colour, it bears a close resemblance to its lilac congener, but its blossoms are a purplish-mauve, with a lemon eye. Singularly enough, my correspondent has also sent me plants of a lilac Primrose, the blooms of which resemble the *Altaica* hitherto so called, but, from the leaves of that kind the foliage differs considerably.—ALEX. DEAN.

Southernwood as a Hedge Plant.—Except as an ordinary border plant, we seldom find this little shrub put to any other use in our gardens. There is just a touch of youthful romance clinging to it when called by its common designation of *Lad's Love*, but we elders are apt to forget our earlier sensations, when many years of every-day life have passed over our heads, and, therefore, value plants less on account of their associations than for their decorative or intrinsic worth. Near here there is growing in a cottage garden a dividing hedge of *Southernwood*, and I think it makes the prettiest fence that I have seen. All who are familiar with its growth know that *Southernwood* has a dense compact habit, is never coarse, and that the foliage has an elegant and almost feathery appearance, which makes the plant, when grown in the form of a hedge, specially graceful and pleasing. This fence originated by the owner of the garden planting a strong old plant deeply in the soil, and thus inducing an abundance of young roots to break out from all the stems. Afterwards, the plant was lifted and divided, and the young ones planted about 10 inches apart to form the fence. These grew rapidly, and are now 2 feet in height and 9 inches through, and require only an occasional trimming to keep them to the needed dimensions. For gardens, where dividing lines of this character are desirable, I think the *Southernwood* is unequalled, and, certainly, nothing can be neater or less troublesome.—A. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Garland Flower (Daphne Cneorum).—This is one of the most striking of all hardy spreading shrubs now in flower, and, as it forms compact little plants about a foot in diameter, and only a few inches in height, it is specially adapted for small beds or borders in villa or suburban gardens. It has small leaves of a fresh green colour, and bears dense tufts or masses of deep rosy sweet-scented flowers. If taken up and potted, it forms a pretty little decorative plant for the greenhouse or cool conservatory.—J. H.

White Wood Lily (Trillium grandiflorum).—This is a fine old plant, that well deserves more general cultivation than it at present receives. It is perfectly hardy, and succeeds well in a moist peaty soil if shaded from hot sunshine. It varies in height from 6 or 8 inches to nearly 2 feet, and flowers in April or May. It makes a nice decorative plant for the greenhouse or conservatory when grown in pots, bearing pure white flowers at the apices of its three-leaved stems. It is now blooming freely out of doors in Mr. Parker's nursery, at Tooting, treated as a pot-plant.—J. H.

The Wigandia at Mentone.—The most conspicuously beautiful objects in the gardens at Mentone in April, are small trees of the well-known *Wigandia*, grown for its leaves only in the London parks. Specimens of it are already nearly 20 ft. high, somewhat conical in shape, and almost covered with large panicles of fine violet-blue flowers, cup-shaped, and each as large as a two-shilling piece. At some little distance off it reminds one of a well-flowered *Paulownia*, but is far handsomer. For temperate and warm countries, it will prove one of the finest ornaments.—V.

German Iris (Iris germanica).—There are few hardy plants nobler in habit or more ubiquitous than the German Iris, or the Blue Flag as it is termed by cottagers. It is one of the very best of all town plants, even if grown for its foliage alone. It commences growth early in spring, when its sword-shaped leaves are conspicuous for their fresh and lively green colour, and it bears tall spikes of rich bluish-purple flowers in May. There are several distinct varieties of this Iris varying in colour, and also in the profusion with which their flowers are borne, but all are beautiful and deserve to be planted in clumps and masses, both in shrubby borders and in neglected parts of the lawn.—F. W. B.

AN ANCIENT ROMAN VILLA GARDEN. (See page 145).

THE KITCHEN GARDEN.

CUCUMBERS IN THE OPEN AIR.

I TRY to grow large quantities of these every year, but the plants suddenly die off when in full bearing. I am having a bed made just now, in the following manner:—It is about 10 yards long, and 4 feet wide; I have it dug out one spit deep, and the soil thrown on the sides; I shall fill up 3 feet deep with long Grass and Nettles, having mown the brinks of my meadows for that purpose; I shall then cover with a foot of good old Cucumber mould and old cowdung, all well mixed with soot. A bed thus made ought, I imagine, to be a good one. My former beds consisted of about 18 inches of fresh long manure from the piggery, well covered with soil, without the soot; but I shall never try that plan again, although, I think, the chief cause of failure was wireworm. Will you kindly inform me how cultivators generally prepare a first-rate bed for ridge Cucumbers?—W. B. C.

[The culture of the Cucumber in the open air is a subject which has hitherto received but comparatively little attention. Market gardeners in the neighbourhood of London have attempted it; but, we believe, most of them have now abandoned it, the result not having proved sufficiently encouraging for them to persevere in the matter. Cuthill, in his pamphlet on "Market Gardening Round London," says:—"I have seen 14 acres of ridge Cucumbers in one man's ground; they are grown under glass, and hardened off, and planted out 6 feet asunder, and 10 feet row from row; hand-glasses are put over them. When they begin to grow, the ground is well mulched with straw, to keep the earth moist and the fruit clean. Gherkens are sown in the open air at once, in well-prepared ground at the above distances; and I have known one party to cut in one day 200,000 fruit, which were all bespoke by pickle merchants. Ever since the commencement of the Potato disease, however, Cucumbers were not grown round London." This was written in 1855. That Cucumbers form a somewhat uncertain crop in open fields all must admit, and that some localities are unsuited to their culture must also be conceded; but while their produce is in so much demand, not only in London, but in all large towns, even among the working classes, we are of opinion that their culture might be profitably extended. At present it is confined to comparatively small spots in one or two counties, the soil and climate of which seem unusually well-adapted for their growth. Small, however, as the area at present under Cucumber cultivation is, it is reported to furnish to the London markets not less than 600 tons a week, during what is termed the Cucumber season. Of these, upwards of 100 tons have been known to be sent to Covent Garden in a single day. Passengers by the Great Northern Railway on reaching the station at Sandy, in Bedfordshire, or that of St. Neot's, in Huntingdonshire, cannot have failed to have remarked light carts laden with square baskets, piled one above the other, arriving at these stations as the train approached. These baskets are full of Cucumbers about to be conveyed to the London and other markets. In the neighbourhood of the stations just named, Cucumbers are grown by the acre in the open field, many cultivators having as many as 10 acres at one time under this description of crop. The soil in the neighbourhood just indicated is, for the most part, a warm lightish loam or gravel, in every way suited to the growth of this esculent. The ground to be planted is well prepared during winter, and again deeply stirred and otherwise put in good order in spring. The seed is then sown about the beginning of May, where the plants are intended to grow, in rows some 4 feet apart, and the plants stand nearly 2 feet asunder in the row. In favourable seasons they soon push into active growth and cover the ground with vines, which, during the latter end of May, the whole of June, and beginning of July, spread in all directions and come into bearing. During their growth, weeding and thinning their superfluous shoots are well attended to, and if the plants should not entirely cover the ground, or wherever blanks occur, Mangel Wurzel is planted in the vacant spaces. At 2, 3, or 4 yards apart are also rows of Onions, set early in the spring and being allowed to run to seed, serve, in some measure, both for shade and shelter. Where Onions are not

used for this purpose, Rye, sown in the autumn 3, 4, or 5 yards apart, and cut as soon as the vines cover the ground, is employed instead; Peas are also, sometimes, used for the same purpose. In this way the ground is induced to produce two or three kinds of crops at the same time, and if one should happen to fail, one or more of the others, as the case may be, to a certain extent takes its place. By the middle of July or earlier, according to the season, the crop is ready for a first gathering, and from that time to the end of September fruit, varying in length from 10 inches to a foot, green, straight, and solid, though sometimes somewhat unshapely, is continually being cut, sometimes to the extent of 3 tons at a time, and that from little more than as many acres. What an acre of Cucumbers realises in the way of money we are unable to say with certainty; but they are stated to yield a good profit to the grower, even if he should get no more than 1d. or 2d. a dozen for them. At these prices sums varying from £20 to £60 an acre, according to the season, are said to have been obtained for them. When gathered they undergo the process of sorting, the best being generally sent to London, second-rate kinds to the provincial markets, and what are small, crooked, or discoloured are given to pigs. Ripe ones are saved for seed, so that little or no waste is ever experienced with crops of this kind. The baskets in which Cucumbers are sent to market are called "pads." In shape they resemble those used by wine merchants, *i.e.*, square with hinged lids, and they generally hold about two bushels. It has often surprised people who think Cucumbers cannot be grown without a frame, how cottagers were able to produce such fine specimens of them as they frequently do at local exhibitions. There is, however, no difficulty in the matter; indeed, the wonder ought to be, that Cucumbers are not more extensively cultivated out of doors during summer than they are. The cottager selects the warmest corner of his garden for them. When the spot has been fixed on, two or three circular holes are made, 3 feet across and about 18 inches deep. These are filled with garden refuse, mixed with some rough manure, and covered about 8 or 10 inches deep with some of the richest and best of the soil that was thrown out of the holes. In the centre are sown four or five seeds an inch deep, and these are protected by a flower-pot or an oiled-paper cap until they have vegetated. In the fields above alluded to, however, no such trouble is taken. The ground is merely, as we have stated, well stirred and worked, thrown into slight ridges, and the seed sown without any bottom-heat or artificial protection whatever. Thus it will be seen how easy it is to have plenty of Cucumbers, with comparatively little expense in the way of preparation or labour; and that, as a crop, they are remunerative is evident from the fact, that ground which would grow cereals or root-crops in perfection is devoted to Cucumbers, even by large cultivators of grain crops.—M.]

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Spent Hops as Manure.—Spent Hops are a very valuable fertiliser. They may be used as an absorbent in the stable, or be composted with the manure, or piled up until rotten, being frequently turned to prevent dry rot.

Cabbage Growing Extraordinary.—A Virginia farmer, from 300,000 plants, set out in November and December, obtained a spring crop of Cabbages amounting in value to 13,000 dollars (£2,600).

Osborn Dwarf Bean.—This is a decided acquisition to the list of first-class vegetables. While I am always ready to appreciate sterling merit in new comers, I never discard old sorts until I feel confident of the superiority of the new; but, after a careful trial, I can confidently say that this is a Bean that may be relied on. It is of dwarf sturdy growth, an enormous cropper, and, where French Beans are required the whole year round, it will be sure to be the principal sort grown.—JAMES GROOM, *Henham Gardens*.

French Beans.—My ground being of a cold character, I generally lose my first crop of these. How can I obviate such a disaster?—W. J. [For the first out-of-door crop, it would be a good plan, in your case, to have a quantity started in small pots at the end of April or beginning of May. These might be placed in very slight heat, so that they would not be over-tender, and should be gradually hardened off towards the middle or end of May, for planting out. The warmest spot in the garden must be selected for them, such as at the foot of a south wall, and some covering must be provided for their shelter.—Ed.]

Fresh Leaves as Manure.—Can I use these without danger of mildew? I have formed a rockery for sub-tropical plants, and have a bank of very sandy gravelly soil, and one of sandy peat, both, of course, very poor. How can I best enrich them? I have plenty of rotten manure and last year's leaves now well rotted.—H. F. [We would advise you either to work plenty of good loam and well-rotted dung into the soil of your banks, or to cast out the original soil in them and make a fresh bed for your plants of the materials just named. Leaves are only useful as manure when thoroughly decayed, and in that state no danger from mildew need be apprehended.—Ed.]

GARDEN DESTROYERS.

SCARING BIRDS.

The mischief done by blackbirds and thrushes, in the kitchen and fruit garden, is chiefly the work of the young birds of the season, which, having been reared in the neighbouring coverts, and acquired their full vigour and activity, on the nourishing food afforded by innumerable slugs, worms, and insects, carried to them by the old ones from gardens and fields, now come to claim a change of diet, and repayment for their services from a share of our fruit. As they are insatiable in devouring it, we are compelled to defend ourselves as well as we can. Nets are useful safeguards, so far as they can be used; springes or nooses of hair or wire are good, but especially twigs, with birdlime, may be resorted to. Nor ought the young blackbirds and thrushes so captured to be thoughtlessly killed and thrown away. They make truly "a dainty dish," either roasted by themselves, or with pigeons, or as an addition in a pigeon pie. The parent birds are not so easily taken, and being in the moult during the fruit season, nourish themselves rather on worms and slugs in the Turnip fields, and are not much seen in gardens. With the first frosty nights of September, a migratory movement towards the south takes place among all the young yearling blackbirds and thrushes, whilst numbers again betake themselves to the hedges and furze coverts near the sea-coasts, and westward especially, where frost is least felt in autumn, and wild berries are most plentiful. The great object, therefore, which gardeners should try to effect, is to scare away the intruders during the season of Strawberries, Cherries, Currants, &c., in July and August. A gun may be occasionally fired in earnest, but its use is always attended with as much danger to children and others, as to the birds. But low-priced squibs and crackers may be lighted and thrown down early in the morning with excellent effect, and every now and then through the day. The very smell of the gunpowder, and smoking of the paper from the exhausted fireworks are alarming to the enemy. In winter time the presence of a pair or two of blackbirds is beneficial to a garden (and more will never stay, so quarrelsome are they), and their song in spring, in concert with that of the thrush, is as delightful there as in the shrubbery or woodlands. Be it observed, above all, that steel traps for birds, in gardens, are things that can never be tolerated. They are instruments of barbarous cruelty even when used for rats. I have known a gamekeeper, who had felt constrained to use them largely, to keep down rabbits, yet speak of them with horror and disgust. At the present season sparrows are in disgrace with gardeners. Let the commonest and cheapest crackers be tried, with assurance of success. If known to be in demand for gardens, these petty fireworks could be made at very small cost. Touchpaper (that is, common brown paper soaked in strong saltpetre-water, and dried) may be readily provided by the gardener himself. Pieces of it, thrown down among his Gooseberries and Currants, would go on smouldering and smoking for an hour, when lighted for the purpose. By such simple means the bird grievance may be much abated in every garden. Turnip fields and Mangolds are greatly benefited by blackbirds and thrushes, which live under the foliage of the crop in August, consuming slugs, beetles, caterpillars, worms, and wireworms. Let them be driven, therefore, as much as possible out of gardens and into the Turnip-fields rather than be killed. R. C. E.

ORIGIN OF THE PHYLLOXERA.

WHATEVER may be the opinion as to the influence of food and climate on man, there can be no doubt that, according as one descends the scale of creation, those influences become more and more apparent, and when, at last, one arrives at those little beings, which I have more especially in view, aphides and the like, we should beware of trusting too much to the classification of entomologists, and considering a plant safe from the ravages of such or such an aphid, because it may have been classed as *A. sambuci*, *A. rosæ*, or *A. dianthi*. Boisduval, in his excellent work on entomology, describes forty-nine species of *Aphis*, mostly classed according to the plants which they infest. I have seen it in some cases, and firmly believe it to hold good in all, that any one of these species, driven to it by starvation, will take to almost any other plant, get naturalised on it, and after the first viviparous generation (and these occur every

eight or ten days) will assume a totally different aspect from what it had in its native habitat. Go, for instance, to the first Elder bush and shake off into your hand a few of those black bloom-covered aphides, looking like very small black Plums, which cover the shoots with their closely packed bodies, and carry them (though, mind, I do not advise it) to your greenhouse, where rows of Fuchsias display their clean and shining foliage, and pour out your aphides on one of their leaves. Now, the Fuchsia is a plant generally free from aphides, and consequently not a favourite with them. Yet, if you return in a fortnight or so, you will find every Fuchsia infested by aphides of a light greenish-white colour, shiny and waxy-looking, much smaller than *A. sambuci*, and very like those of the Carnation. It has always been my opinion that the Phylloxera, in France, is neither a new creation, nor an importation with foreign Vines, but a parasite of some plant either growing as weeds, or cultivated between the Vines of the first Vineyards attacked; the plants, in question, having at that time either been no longer cultivated, or, if weeds, more effectually rooted up than usual, their parasites have, from sheer starvation, been driven to the Vine, where they became acclimatised, and finally changed into the actual Phylloxera as now known. At the last sitting of the Horticultural Society of France, M. Rivière, of the Luxembourg and Jardin du Hamma, Algiers, in describing the culture of the Eucalyptus globulus in that country, stated that in some vast plains planted with young trees, great numbers had been destroyed by the larva of a small beetle inhabiting certain wild plants which had been ploughed up in preparing the ground for the Eucalypti. Now, here is a case in point: a tree from the Antipodes, of a nature totally different from any growing in Algeria, and very strongly aromatic, is at once adopted by a creature far more highly organised than any greenfly. Well, the food being once changed, the change in the appearance of the insect is only an affair of time; and we shall have a new pest, the Eucalyptus beetle. As of animals, so of vegetables, and I am as firmly convinced as a person can be of anything of which he has not ocular demonstration, that the Potato disease, the *oidium* of the Vine, and many other vegetable parasites, originally came from plants most probably very different from Potatoes and Vines, although their present characteristics might be so peculiar and well defined as to lead botanists to deny that they could possibly at any time have been the parasites of anything else. F. P.

THE NEW POTATO BEETLE.

As, happily, readers of this paper have had no experience with the Colorado beetle as yet, but are anticipating its invasion of their Potato fields during the coming season, they will, of course, be interested in learning the results of observations and experience where this pest has been prevalent for several years past. And first I would state it has been found, as a general rule, that it takes three years for the beetles to attain their strength of numbers and mischief in a locality. That is to say, their first appearance is usually in small numbers, and only in a few fields of a township or neighbourhood; the next year there will be found abundance, and destructive to some fields if not opposed; then the third year, and for several years afterwards, they will be in full force.

Use of Paris Green.

Poisoning with Paris green is found the most effective and practical mode of fighting the beetle. In regard to this remedy there is need of some intelligence and caution. The use of this, or other poison, will not be found necessary the first season of the appearance of the beetles, as they can easily be picked off by hand, when their numbers are few. And also the second year, we found it best to pick off by hand the beetles that appeared early in the season, if possible, before they laid their eggs; as the number of the larvæ was thereby greatly lessened, and it is the larvæ or young insects that do the most mischief, though the mature beetles are not lacking in destructiveness, and when too numerous to be picked off by hand we dose them with the poison. About the first week in July the young larvæ begin to appear; and then successive broods continue to hatch out until frosts come, or the Potato tops are ripe. As soon as these larvæ appear we use the Paris green. Various methods of applying it have been practised. Until last year the majority of our farmers mixed the poison with thirty or forty times its bulk of plaster, flour, or fine middlings—any fine substance that will give it bulk—then dusted the mixture through a perforated tin can, like a kitchen dredging box, on the tops of the plants, where the pests were seen. But this mode of application is liable to cause serious harm to the persons who do the work, as the green is so virulent a poison that a very little of the dust inhaled into the lungs or the nose is apt to cause painful irritation. The eyes also must be protected, and any sore or scratch upon the hands will suffer from the poison if any

chances to reach it. Hence we prefer mixing the Paris green with water, and sprinkling this on the Potato tops. A heaped tablespoonful of the green to a ten-quart pail of water is about the right strength. The green does not dissolve in the water, only mixes with it, giving it a pale green colour, but settling to the bottom if left to stand a few moments. On this account the mixture cannot be prepared in barrels and conveyed to the field, though it is common to convey the water in this way, to save labour, and put in the green with a spoon, for each bucketful. The mode of sprinkling the plants is capable of some improvement. The use of a garden watering-can is the simplest, but not sufficiently economical, unless the plants are in rows and quite badly infested. The more common mode is to take a small broom with a short handle—a common clothes broom will do—and dip this into the pail of liquid, then sprinkle it on the plants. With a little practice an active boy or man will do this work very expertly. The dipping of the broom into the liquid keeps it stirred, so as to prevent the green from settling to the bottom, as it will do to some extent in a sprinkling can. The number of applications of the poison required will, of course, depend on the abundance of the insects, and somewhat on the weather. If the crop is badly infested, and the weather warm, so that the larvæ hatch rapidly, it will be necessary to sprinkle the plants once a week for several weeks. At other times, once in ten days will suffice; and commonly it is not necessary to apply the liquid to all the plants—some being exempt from the beetles and larvæ. The amount of Paris green required for an acre varies from 2 to 4 lbs. The extensive use of this poisonous drug as a remedy for the Potato beetle has, of course, greatly stimulated its manufacture; and, as usual in such cases, there is a great deal of adulteration of the article, and the sale of cheap and poor samples for the pure and genuine. Country druggists are liable to be imposed upon in this way, as well as their customers, especially when their supplies are obtained from brokers instead of directly from the manufacturers.

Precautionary Instructions.

The following is from a circular issued by Messrs. Raynolds, and sent to all who purchase Paris green of them:—As the handling of dry Paris green, especially by persons unaccustomed to its use, is attended with considerable risk and often followed by serious consequences, we make the following suggestions founded on our experience as manufacturers: All packages, whether large or small, should be plainly marked poison. There is great danger in the mixing of this green for Potato bug, owing to the fine dust which arises in the process, which is inhaled, and also rapidly absorbed by the pores of the skin, especially if the person using it should be in a state of perspiration. To guard against this, the hands and face (particularly the nostrils) should be protected as much as possible, and should be carefully washed after working with it, or with any of the preparations of which it is an ingredient. As it penetrates and poisons wood—gets into the seams and crevices of articles made of metal—and even into earthenware that is at all porous; all household utensils, or anything in barn or stable (which cattle or horses could have access to) in which the article may have been mixed, or from which it has been used, should be carefully set aside, and never again used for any other purpose. Malignant sores are not unfrequently caused by scratching the skin when itching or irritated from handling the green. It should be constantly borne in mind that it is a more dangerous and deadly poison than arsenic, and planters and others, when purchasing, should be duly cautioned to exercise the utmost care in using it.

Remedy for the Poison.

The free use of milk as a beverage is recommended, but we have found hydrated per-oxide of iron (a simple harmless remedy), the best antidote. Sores caused by the green should be well covered with it, as with an ordinary salve, and a teaspoonful in a wine-glass of water should be taken twice a day, internally, while working with the green. This remedy can be obtained from any druggist or chemist. The consumption of Paris green has largely increased within a few years, and the article is now applied to such a variety of purposes, that carelessness in its use, or ignorance of its highly dangerous properties on the part of those who use it, cannot fail to produce the most deplorable results.

[The above valuable instructions, published in the *Albany Cultivator*, by Mr. M. B. Bateman, of Ohio, deserve to be borne in mind by Potato cultivators.]

Vine Insects.—The enclosed, my gardener says, eat his Vine leaves during the night. He has not seen similar ones before, and he asks you to be good enough to tell him what they are, and what means you can suggest for getting rid of them?—Westwood. [The insect sent is a beetle named *Otiorhynchus sulcatus*, which is very destructive both in the larval and perfect state, especially the former. Fern growers suffer greatly from it. A careful and persistent search among the earth at the roots for the whitish grubs, is the only effectual means that we know of getting rid of it.—A. M.]

THE PROPAGATOR.

CULTURE OF GREVILLEAS.

AMONG New Holland plants which have been brought into cultivation, those belonging to the family of the *Proteaceæ* occupy one of the foremost ranks. They are, however, rarely met with in our gardens, notwithstanding the elegance of their foliage, and the beauty and singularity of their flowers. This, we believe, is to be attributed to the difficulty which is experienced in propagating them, and on this subject we shall say a few words. We shall here only mention two genera of the family, viz.: The *Grevilleas* and the *Hakeas*. The genus *Grevillea* comprises a very large number of species, some of which are easily struck from cuttings made in the usual manner, but the greater number of them are propagated with great difficulty, either in this way or by means of layers. These two processes have, consequently, been abandoned, and, instead of them, grafting has been substituted successfully. The stock employed is *Grevillea robusta*, seeds of which are easily procured in abundance and germinate readily. I have grafted, says V. Viviani-Morel in *Revue Horticole*, on this species, *Grevillea Manglesii*, *G. Trobei*, *G. longifolia*, *G. Bauerii*, &c., all of which do well and grow with great vigour when treated thus, and I have no doubt that their culture is thereby rendered more easy.

Hakeas.

The genus *Hakea* succeeds equally well when grafted on the same stock, the grafts uniting rapidly, and with great solidity, the species *H. Lambertii*, *H. gibbosa*, and *H. carinata*, especially, have given most satisfactory results. I have tried *Protea argentea* on the same stock, but it has exhibited little vigour of growth, and appears to maintain its vitality with difficulty. When grafting any of these subjects, I proceed as follows:—If the stocks are not too large, I place the grafts under cloches, otherwise in a glazed frame in the propagating-house, taking care to expose the grafts well to the lighted side of the house. Side cleft-grafting, appears to be firmest and most solid method, but veneering or ordinary cleft-grafting may be also employed. The most suitable time for operating seems to be in April and May, but, as these plants are always in a state of growth, except during winter, I think they might be grafted, without any disadvantage, from the time they begin to grow in spring until October. By grafting early in the season, however, handsome and well-grown plants will be formed by the time that autumn arrives.

Orchids from Cuttings.—About midsummer some few years ago we had a grand flower show, which was largely supported by plants from our establishment, both in the competing classes and for exhibition only. Amongst our Orchids we showed a fine specimen of *Aërides odoratum*, which was a little one-sided. We had many larger plants of the *Aërides*, but they were too heavy to move; therefore, in order to make perfect our one-sided specimen, the head gardener unscrupulously cut the very finest branches laden with flower-spikes off the plants left at home, and ingeniously fixed them in the pot in which the show specimen was growing; the result was the finest plant of *Aërides odoratum*, perhaps, ever seen. All went well, and we staged our *Aërides* in the class of the best Orchids in the exhibition. When admitted, after the judges had finished their work, I observed that our specimen was awarded the first prize, a circumstance at which I was pleased; but dare not go near it for fear that the inserted pieces would look shrivelled, and that our dishonesty would be discovered. We brought home our plants at night and next day I was surprised to find that the recently cut branches did not shrivel in the least, nor have they since. They took to their new quarters most kindly, and grew quite as well as if roots had been attached to them when put in. The gardener, however, informed me that had the branches been severed and inserted before the blooms were fully expanded they would have shrivelled, but that when the flowers were mature, no visible signs of the fraud could be detected.—F.

Water Pressure in Fountains.—A reservoir 20 ft. square and 10 ft. deep is filled with water and connected by means of a 2 in. pipe with a circular basin 9 ft. in diameter and 4 ft. 6 in. in depth, 150 yards away; how high would the water rise in a $\frac{1}{2}$ in. jet, the difference of level being 12 ft.?—W. S. [The size of the lower circular basin has nothing to do with the question, the pipe leading from the reservoir and terminating in the jet instead of opening into the lower basin. From the well-known law of hydrostatics, the water from the jet will rise to nearly the same height as that in the reservoir.—Ed.]

THE INDOOR GARDEN.

CURCULIGO RECURVATA.

THIS plant is one of the most graceful of those generally grown for indoor decorative purposes, and it so nearly resembles some of the Palms in habit, that it might easily be mistaken for some member of that family. Its value for ornamental purposes consists in its long lance-shaped leaves being of a fresh green colour, and gracefully recurved on all sides. As a table plant it has few equals, and deserves more extended culture for that purpose alone. Its variegated variety is still more handsome, each leaf being boldly striped with creamy-white or pale yellow. A pretty little specimen of this plant occupied a prominent position in Mr. Bull's collection of plants

pots filled with moist fibrous peat, with the addition of a little turfy loam, but they must not on any account be allowed to become dry at the root. In a general way, however, planting out will be found to be the best plan, as it is less troublesome to the cultivator, and gives better results in the long run. When planted out in a cool peaty compost, and trained on the roof of a partially-shaded greenhouse, Lapagerias (both red and white) seldom fail to make luxuriant growths, and to flower abundantly. For corridors, connecting the house with the conservatory, such plants are peculiarly well adapted, and never fail to bloom well if liberally treated with regard to moisture when making their growth. There are several distinct varieties of the rosy-flowered form, differing from each other in size, colour, and markings. The white-flowered kind is, however, the greatest favourite with many, and it never looks better than when trained overhead, so that one can view its pearly whiteness against the deep green foliage of the plant itself. At one time it was

Curculigo recurvata variegata.

suitable for table decorations, shown the other day at South Kensington. This variety grows well in an ordinary plant-stove, or in a warm greenhouse; and, in order to exhibit its brilliant variegation to advantage, its foliage should be carefully sponged occasionally with clean soft water. Young plants of this *Curculigo* should be potted in a compost, consisting of loam and peat, to which should be added sufficient well-washed sandstone grit to keep the whole in a porous state.

LAPAGERIAS.

THOUGH the rosy and white flowered Lapagerias are amongst the most beautiful of all cool greenhouse climbers, they are not, as a rule, well grown by amateur cultivators. They do well enough in

thought that Lapagerias were difficult to propagate, inasmuch as cuttings of them, taken off and inserted in the usual way, would often keep fresh for a year or more, and, at the end of that time, be no nearer rooting than when first put in. Seed, however, if it can be obtained, is found to germinate freely; and shoots, a yard or more in length, twined round the top of the pots, or inserted in the border and covered with soil, form roots at some of the points, and soon make nice little plants. Some make a slight incision at each joint—an operation which, it is thought, hastens the production of roots. In this way Mr. Speed, of Chatsworth, raises plants of Lapagerias as readily as he does Geraniums, his specimens being planted in a deep cool border, kept constantly moist, in one of the Camellia houses, in which the plants themselves grow with extraordinary vigour, and soon cover the light wire trellises with deep green foliage and rosy or white flowers, according to the variety thus treated. B.

FENCES.

By JAMES GRIGOR.

MANY varieties of trees and shrubs have been recommended for hedge fencing, all of which are no doubt more or less suited for the purposes of inclosure; but, as there are some kinds so eminently adapted beyond others, it becomes necessary to distinguish which they are, and to insist upon their being adopted accordingly. Their adoption, however, must depend upon certain circumstances, viz., the character and situation of the soil. As in all other things, Nature has observed a beautiful adaptation amongst trees and shrubs with reference to the food they imbibe, and the peculiar habitation they affect; and it really requires no great discernment to follow her correctly throughout this interesting distribution.

The Hawthorn (*Cratægus Oxyacantha*).

Of all the trees and shrubs suited to the climate of Britain, none has been found so eligible for hedge fences as the common White-thorn. It is true that in mountainous and exposed situations, where a combination of circumstances operate against vegetation, it refuses to grow with that vigour which characterises it throughout the plains and cultivated uplands of England. Its province, however, might be easily extended beyond its present limits by using as its forerunner lines or strips of Scotch Pine (*Pinus sylvestris*) planted on each side of the site intended for the Hawthorn hedge, but not too near to rob the part to be sheltered of its nourishment. The Hawthorn, when properly treated, is a very fast grower, and, under most circumstances, is considered to be very ornamental. As a fence, it is smooth, stubborn, and long-lived. It is easily reared; and in this respect, at least, it has the advantage over either the Holly, Crab, or Sloe. As is well known, it is a deciduous tree, shedding its leaves in winter, and, therefore, better suited to protect crops than to shelter cattle, though, in this last respect, it is by no means to be rejected; for though it is not equal to the Beech in warmth, it has a decided advantage over that tree, as a fence, in becoming an impenetrable barrier to all sorts of cattle. It should not be intermixed with other sorts of trees, for, though growing tolerably well with the Holly and Beech in some soils, the treatment in an essential point, viz., trimming, which is insisted upon in its proper place, is not applicable to all.

Soil and Situation.—The soil it delights in most is a hazelly loam, or, if not too retentive of water, a good clay bottom. At the same time, it will grow well on sand, if free from iron, and on almost every other description of land except chalk and pure gravel. Even on these, artificial means will enable it to grow freely. By displacing the gravel and chalk, and filling up the trench to the depth of 3 feet with loam, I have found that such sub-soils will not hinder it from reaching to the height of 5 feet in six years. On wet soil it is soon covered with Lichen, a sure indication that it is not in a thriving state.

The Preparation of the Soil.—This is, perhaps, the most important process connected with hedge fencing, though it is one which is the least of all attended to. Nothing can repay the planter more satisfactorily than the previous management of the land, and I have adopted it as a rule whenever called upon to form a fence, if the proprietor should object to go to the expense of having the land trenched at least to the depth of two feet, and well manured, to decline the undertaking altogether. This trenching and manuring I hold to be necessary under all circumstances, whether the "hedge and ditch" form be adopted or the sets planted on the level surface of the ground, or on a slope. If practicable, the land should be trenched several months before the time of planting, and immediately manured, so that the manure and the soil may be completely incorporated when the trench is opened up for the reception of the plants. The trench should be at least 2½ feet in width. It is delightful to witness the vigour and rapidity of growth which a hedge will assume after the soil is prepared in this way, the plants generally maintaining a uniformity of action, such as an unprepared bed never displays. It is the grossest thoughtlessness to suppose that the Hawthorn, any more than Wheat or Turnips, will rise luxuriantly unless excited by the richness of the soil, either naturally, or by the application of artificial means. Amongst other advantages, I may mention that well-prepared soil, compared with that which has not been manured, will save all the expense of protecting the fence for about two years, an item which must be very heavy in districts where young Fir poles are scarce. Hence the necessity of commencing the work in a proper and reasonable way.

The Construction of the Bed in which the Plants are Placed.—This is of essential importance, and ought to be regulated by local circumstances. If, for instance, the soil be dry, a ditch will not be required to drain the land; but if wood to protect the fence cannot be had, of course a ditch becomes necessary. If the soil, again, has too much moisture, a ditch is to be preferred even in

cases where wood is plentiful. The mode in which the sites for hedges are formed at present throughout England is in many cases highly objectionable. What is called the "hedge and ditch plan" is one of the best, though in many cases imperfectly executed. It is effected by digging out a ditch parallel to the line on which it is intended to place the fence, 5 feet in width at top, 3 feet in depth, and 1 foot wide at bottom: the soil out of this channel is thrown upon that side where the hedge is to be planted, thus forming a sort of ridge for the plants to grow on. Now, with regard to this plan it is to be observed that it is advantageous only either in soils which have too much moisture, or wherever wood for paling to protect the hedge cannot be procured conveniently. This should be invariably borne in mind, and I repeat it now, because it has become common to proceed with a ditch under all circumstances. If posts and rails can be had, it is very plain that there can be no propriety in forming a ditch where there is no superfluous moisture to draw off. And again, if formed only for a fence to the hedge, there can be no necessity for keeping it open for an indefinite time after the hedge has arrived at maturity. In wet soils, as already observed, such a ditch is indispensable; but wherever the soil is favourable, it is rather a hindrance to the growth of the hedge, which it must of course limit to draw its nourishment from one side only, as well as drain off a part of the moisture from its already contracted resources. It follows, therefore, that at the end of three or four years, when the hedge will require no further protection, the ditch should be filled, and the land brought into cultivation. I have already described the usual way of forming hedge and ditch; but the plan is susceptible of a great improvement, which is as follows:—Suppose a plane surface; after the preparation of the soil, described elsewhere, insert the plants in an upright position with the roots inclining to the field side; at 12 inches behind the line thus formed by the plants, commence the side of the ditch, the mould from which should be thrown over the line of the plants, in order to form a bank to protect the fence on the inner, or field side. At this rate, you have a ditch on the outer, and a bank of earth on the inner side, which latter, if topped with small branches or brushwood, will form a protection to the hedge as long as necessary. One of the common plans is to insert the Thorns on the brink of the ditch, which is often washed in with rain; and again, the plants are not unfrequently placed on the top of the mound, instead of the surface, level with the adjoining land. It is moreover to be observed that the ridge or bank on the inner side must not be put close upon the roots, for access to air is indispensable to the proper performance of their functions. This is no doubt the reason why hedges buried under a high mound of earth succeed so indifferently. The plan pursued throughout most parts of England, of forming a ridge or bank of soil, and planting the Quicks on the top of it, is so thoroughly absurd, that one wonders how men conversant with the usual operation of the elements should have ever thought of it. No hedge can prosper if planted in this way. The rain comes, but it washes down the sides of the bank only; the sun shines upon it, but as there is no moisture in the ridge, his influences tend rather in this case to hinder vegetation; frosts loosen the surface, and the soil moulders away from the roots, which, in the course of time, are exposed for the searching winds to operate upon. Hence it is that throughout England there is not a single good close fence founded on this plan; the result being that even after ten or fifteen years' nursing the hedge has to be patched and mended with dead branches. In fact, if such a fence were to be kept clean, as all fences should be, this necessary operation would, in the course of a year or two, cause it to fall to pieces; for the roots of rank herbage, Brambles, &c., which surround it, bind the bank together, so that the weeds and rubbish may be truly said to form a part of the system. Added to this is the great width of the bank, raised, too, by impoverishing the soil on each side, which are in themselves sufficient reasons for rejecting this injurious though common mode of preparing sites for fences. The object of every planter and improver is to form at once an immediate and durable fence, and for this purpose there ought to be a more liberal provision made for the necessary expenses at its first formation. Under all ordinary circumstances, where the soil is not too damp, my plan has been, after trenching and manuring, to plant on the plane surface of the ground, in which cases the roots have the full benefit of the soil on both sides, the full benefit of the rains from heaven, and, instead of being baked by his rays, the full benefit of the sun also. In four years such a fence is strong and impenetrable, requiring no protection, and, if assisted by manuring its weak parts during its progress to maturity, presenting a beautiful, regular, and complete appearance.

Time for Planting.—The best season for planting is immediately after the fall of the leaf in autumn; for at that juncture a tree is at complete rest, and has not commenced to prepare the necessary secretion for its support during the following spring and summer. Let it prepare it therefore in its new station. There is a

slight perspiratory action going on from the bark of trees even in winter, so that the more humid the atmosphere is the less will a plant suffer by being removed. Autumn, then, is, on this account, also the more eligible season. It is not to be denied that many hedges are planted and succeed tolerably in the months of February and March; but, it is equally certain that, in many seasons, during these months the atmosphere is so cold and dry as materially to affect vegetation. I am confident the latter part of October and the commencement of November is the best time both for the Hawthorns themselves, and for getting the best plants to be had at the nurseries.

The Choice of Plants.—This is a subject on which a variety of opinions prevail, some maintaining that it is better even to sow the Haws in the line where they ought to remain. This mode, as also the planting of one or two year's seedlings, can never find general favour with planters, on account of the length of time exhausted in protecting the fence, and consequent expense of cleaning; for a hedge which grows but slowly requires a great deal more attention than a strong one, which rapidly covers the soil, and gets the mastery over the weeds. Generally, the age of plants used for fences is four years, either one-year seedlings, which, after being transplanted, have stood three years in lines, or two years' seedlings, which have stood two years in the nursery lines. The size, however, is of more importance than the age, and the thickness of the stem is to be looked to, and not the height of the plant. Those of the thickness of a man's finger, or such as are an inch-and-a-half in circumference, are to be preferred to any other; and the oftener they have undergone the process of transplantation in the nursery the better will they be furnished with fibrous roots, a consideration which should be always borne in mind. There is a plan, not often practised by respectable nurserymen, but very common with market gardeners, of lifting a large quantity of the Whitethorn at a certain time and binding them in bundles about the size of a sheaf of Corn. Those bundles are taken to market with their roots exposed to the sun and wind at certain periods for a whole day, and if left unsold are taken home to undergo the same treatment till disposed of. Such plants are said to have "stood the market," and are quite worthless. Akin to this process is the nurseryman's practice of counting up several thousands of Hawthorn plants, binding them in hundreds or in parcels of two or three hundreds each, and laying them so bound into the soil to await a customer, it may be, for several months. A great proportion of the plants so treated must die, because in covering them up the soil does not get to the centre of the bundle, which usually falls a prey to the searching winds of spring. Plants which are so lifted before they are actually required should have the full benefit of the soil by being laid in thinly, so that the roots may not in any case touch or rest against each other. Of course, plants which have been lifted carefully, with few of their roots injured, are to be preferred to those which are in other respects better suited. A small plant, with its root uninjured, is better than a strong plant, as to size, with an indifferent root.

The Preparation of the Plants.—This consists in cutting off the tops to within 2 inches of the ground mark, so that when set they will appear this length above the surface of the soil. This is the only operation connected with hedge-fencing which I cannot exactly reconcile with physiological principles. Experience has always convinced me that the plants thrive better when so treated, though it is generally thought that the branches and leaves are required to assist in renovating the roots which suffer by transplantation. Be this as it may, it is unquestionable that plants which are headed-down in the way recommended, shoot out much more vigorously than those which are planted with their tops on. The roots should not be touched with the pruning-knife at all, for the removal of every healthy root, and especially the spongioles, which are most apt to be removed, is the loss of as many life agents. Plants, indeed, under favourable circumstances, have the power of forming new spongioles, but this is by no means a reason why those roots which are already formed should be displaced. It is also important that, previous to planting, the Quicks should be sorted, as near as possible, to a uniform size; so that no plant may have the advantage over another in rising exuberantly to the detriment of its weaker neighbours, as is always the case when different sizes are used. Nurserymen in general make it a point to assort the plants in a proper method; but it is as well that planters should know the importance of getting them as near as possible of an equal size and description.

Planting.—In this operation the first thing to be done is to stretch a line, so that it may run along the centre of the prepared ground. Close to this line, which will form one side of it, a perpendicular trench is to be opened with the spade, sufficiently deep and roomy to hold all the roots of the plants, which are to be placed 6 inches apart from each other, and as deep as they had been in the nursery lines. In cases where the plants are very strong, the space between each plant should be 8 inches. Over the roots a sufficient

portion of mould is to be placed with the hand in order to keep them firm in their places, when an additional quantity is to be filled in with the spade. The line of plants is then to be trod gently, yet firmly, with the foot, when the remainder of the soil may be levelled in about the stems of the plants, and the surface finally smoothened with a garden-rake. The plan of planting with the dibble is highly improper, because it necessarily gathers all the roots together into a small compass; indeed, careless labourers will cut off the roots rather than take the trouble to put them all into the hole formed with the dibble. The opening of a trench with the plough is also to be condemned on account of its forming a firm smooth surface at the bottom, through which the roots can with difficulty penetrate. It is, besides, impossible to do the work with any degree of neatness where the plough is introduced; but the chief consideration is, that where it is used the hedge will not grow so well as in those cases where the spade is adopted.

Protection.—This should follow as a matter of course. Many a well-formed and carefully planted hedge is ruined for want of being guarded from the attacks of cattle browsing upon them; and many more are retarded by the fences set around them being either incomplete, or allowed, after any accidental inroad upon them, to remain without being mended. The nature of the protection will depend entirely on local circumstances. In all cases where wood is plentiful, posts and rails are to be adopted. The posts should be 4½ feet in length, pointed or sharpened at the end with an axe, and driven into the ground with a mallet at the distance of 4½ feet from each other, and to the depth of 15 inches. Various other contrivances have been adopted with wood, in order to protect hedges, but in no form has this material been used to such advantage as in the shape of posts and rails. Common hurdles, indeed, have, in some instances, been known to protect a hedge until it has arrived at maturity, but in general they are deficient in strength and firmness, while their cost is not less than that of the other. Mere brushwood loppings of trees or old hedges, and all sorts of wattled works, however perfect in themselves, are not suited to resist cattle unless placed on the top of a bank, and this bank should be only adopted in conjunction with a ditch, as I shall notice presently. With the exception, then of the posts and rails, and the various modifications of this kind of hedge-fencing, I do not hesitate to pronounce all other sorts of protection to a hedge, when used on the plane surface of a field, as inefficient, and a source only of continual trouble and expense. The other kind of protection to a newly planted hedge has been already adverted to, and consists of a ditch dug out on one side, and a bank formed on the other with the soil taken out of the ditch. This bank should be topped with any sort of strong underwood most convenient to be had, but the most effectual resistance to cattle is formed of the loppings of old Hawthorn hedges, Blackthorn, or Sloe.

Cleaning.—When a hedge is planted, it should have the full benefit of the soil, and no weeds should be allowed to grow. Weeds rob the soil of its nourishment, choke the young plants, and prevent the rains from getting at their roots. The bottom of the hedge should be regularly hoed with a common hoe (for slovenly gardeners with a Dutch hoe leave half of the weeds around the stems of the plants), and the weeds raked off as soon as the hoeing is completed. There is no operation performed so abominably throughout England as that of hoeing. Whether it be Turnips, Cabbages, or hedge-bottoms, the same slovenly uniformity is observable throughout; and I almost despair of ever seeing this necessary work executed so well as it ought to be. The Scotch, who rather excel in forming hedge-fences, very much neglect the cleaning department. The English, again, clean not at all; indeed, the weeds and herbage, according to the present system, form a part of the hedge, and if they were regularly removed, the fence would be in danger of falling to pieces. It is impossible to lay down rules as to the periods when the hoeing and raking should be performed. It may be mentioned, however, that so soon as the weeds appear, they should be destroyed, and the timely execution of this work will save a great deal of expense and trouble. Nothing in the whole circle of gardening or agriculture has a better appearance than neatly kept hedge-bottoms, and nothing more bespeaks prevailing order throughout a garden, a farm, or an estate. Ivy and Honeysuckle are to be treated in this case as weeds, and should be wholly eradicated. They overcome, and ultimately smother, all hedge-plants within their reach.

Pruning or Trimming.—A hedge should not be pruned till the end of the third year, when it will require to be shaped and moulded to a certain degree of uniformity. The branches and leaves should be left untouched for this period, in order to strengthen the stems. No hedge can have strong stems unless the branches from those stems are allowed to grow, and the leaves on those branches to elaborate the sap fit for the support of the plant. This assertion is abundantly proved by every plant in a hedge which is

allowed to shoot up into a tree; such plants, in the course of a few years, having stems many times thicker than any of the others which are regularly shorn of their foliage. In trimming the Hawthorn, the hedge-shears should be discarded altogether, for they do not make a clean cut, and it is besides a tedious, and, consequently, an expensive method. The only implement which expert hedgers use is the hedge-bill, of which there are several varieties; and it is astonishing what beautiful work a dexterous hand executes with this tool.

The Sloe (*Prunus spinosa*).

This plant is by some called the Spring Plum; by others, the Sloe Thorn; but, most generally, it goes under the name of the Sloe or Blackthorn. In situations where the soil is loamy and not overcharged with moisture, this shrub is found to answer very well for the purpose of fences. It grows rapidly, has formidable spines, and is very lasting. It has no claim upon our attention, however, beyond the Hawthorn, whilst it falls very short of having all the recommendations applicable to that tree. The great fault of the Sloe is its suckers, which it sends up in such profusion as to threaten the usurpation of whole fields in its neighbourhood. The plants should be invariably grown from seed, in which case few or no suckers will rise from the roots. The fruit are ripe in October, when they should be gathered and laid in a heap, mixed with sand, in the open air, and turned over several times during winter until the pulp is decomposed. Advantage should be taken of open weather during January for the purpose of sowing them, which should be done in beds, with a covering of an inch-and-a-quarter in depth. When two years old they should be transplanted into rows to remain for one year, when they will be fit to be removed into hedge-lines as recommended for the Hawthorn, to which reference is made for all necessary instructions. The Sloe being deciduous, it is to be planted chiefly to divide arable fields.

The Crab or Wild Apple (*Pyrus Malus*).

When strong plants of this tree are used, they will form a fence even in a shorter time than the Hawthorn. They should be selected of six or seven years' age, the tops cut off to within 4 or 5 inches of the root, and planted at a foot apart. In rich, well-prepared soil, a bush of shoots will rise from each stool, many of which will measure 3 feet in length and be robust in proportion; but it has one great disqualification which alone prevents it from being in general use—its liability to be attacked by caterpillars. So fond are these insects of fastening upon this tree that I have often seen the leaves for hundreds of yards completely eaten off by them; and when this takes place before the hedge has arrived at maturity, the danger is almost irreparable. It often happens that for several years a fence of this description may remain unattacked; and, on the other hand, it as frequently occurs that for two or three years successively they become a prey to those insects. In planting a hedge of this description it is very important to ascertain that the plants used have been raised from the true wild Crab; for such as are raised from the seeds of cultivated Apples, and even cultivated wildings, are found to be almost thornless, and, consequently, unfit for the purposes of defence. Reckoning the cost of the plants at 1d. each, a price at which they may be had at any nursery, the expense of forming the hedge complete, without fencing, would be 1s. 10d. per perch, being 10d. more than the cost of a Hawthorn fence for the same space. For the information of those who are desirous of raising the plants, I annex the process:—When the Crabs are gathered, which will be in October, they should be carried to a rot-heap in the open air and mixed with mould to hasten decomposition. If turned several times during winter, the pulp will be so completely rotten that the seeds will be found detached from it sufficiently to ensure germination when sown, which should be attended to during open weather in the month of March. They should be covered to the depth of an inch, and, when two years old, transplanted into nursery-lines, there to remain for a similar time, when they should undergo another transplantation for one year previous to their being planted finally out. Thus they will be five years old. At the end of three years the hedge formed of such plants should be pruned or switched with a hedge-bill into a regular form, as recommended for the Hawthorn, and at four years old it will be strong enough to stand unprotected as a fence. In grounds near to dwellings, or of an ornamental character, unfrequented by passengers, it would confer great beauty if a strong plant was left every twenty yards to shoot up into a tree, to be grafted with one or other of the ornamental Siberian Crabs, or some of the smaller cider Apples which have little or no shade.

The Holly (*Ilex Aquifolium*).

For home districts, and especially for grazing grounds, no tree presents so many qualifications for a hedge as the Holly. Being a close-growing shrub, and an evergreen, it forms a most desirable

shelter for cattle pasturing in fields surrounded by it; and, as it grows much better than the Hawthorn under hedgerow trees (which are absolutely necessary around grazing lands), it ought in every case to be adopted in enclosing meadows and pastures not overcharged with moisture. It is, besides, a much more beautiful object than the Hawthorn; and, being recommended near to dwellings, it is important to recollect that it is a tree which does not exhale any perceptible vapour. Added to these are the following important considerations:—First, its keeping itself almost free from weeds, for from the closeness of its branches at bottom, it excludes the air so effectually that none can grow; secondly, its not being liable to the attacks of any insects; and, thirdly, its not being resorted to by birds. The reasons why it has not been so generally adopted as it deserves are—first, a prevalent idea that it is a slow grower; and, secondly, the high price of the plants. A strict compliance with the rules laid down for the preparation of the soil and for the choice of plants, will obviate the first objection; and the other may be modified considerably by every one raising the plants for himself, agreeably to the instructions detailed.

Soil and Situation.—Let no one be deterred from planting the Holly from an idea that the soil is not suitable for it, providing it is not bog land, or soil absolutely saturated with wet. It certainly triumphs over more varied localities than the Hawthorn; it is found flourishing on dry gravelly land, as well as on strong clay. Sand, and sandy loam, are the soils it delights in most, and, when it meets with these, it shoots up luxuriantly.

Preparation of the Soil.—As in the case of the Hawthorn, and all other hedge trees, the site intended for the Holly should be trenched and manured several months before the time of planting. The trench in this case I would recommend to be a yard in width, and at least a yard in depth. It matters not what sort of manure be used, for, by the time the soil is turned up, all sorts will be pretty well reduced to a certain quality. The chief thing is to have the soil loose and fertile, and, to accomplish the latter, nothing can be better than well-rotted farm-yard manure. By the deep trenching recommended, the soil will be raised about half a foot higher than it was before, but it will afterwards sink down, so that none of it should be removed.

Site for the Plants.—The plane surface, with a fence on either side, is best; but where the materials for fencing cannot be procured, cast a ditch on one side, and raise a mound on the other with the soil taken out of the ditch, and if the soil should be insufficient for that purpose, top it with dead branches such as can be got in the neighbourhood. The bank raised must not be immediately over the roots of the plants, for a certain degree of air is necessary to their free development; the side of it, therefore, should be 15 inches away from the plants.

Time for Planting.—The best season for planting is from November till March; for, though the Holly and all evergreens are often removed during summer, the most eligible season must be that in which there is the least chance of their being affected by evaporation. The particular day to be chosen is when the atmosphere is humid, and the elements still; for, though some may think these unnecessary precautions, they will assuredly tell well on the first year's growth of the plants. It must be remembered that the Holly is rather a shy plant to remove; hence the necessity of choosing the cloudiest weather for the purpose.

Choice of Plants.—No plants should be used except those which had been transplanted the previous year; in which case every plant will be furnished with an abundance of fibrous roots, and, though they may not look so well as those which had stood in one place for two or three years, yet their certainty of growing overbalances every other consideration. Plants of six to ten years of age should be preferred to younger ones, for young plants are proverbial for the slowness of their growth, but, when they get to about eight years of age, they commence to grow rapidly. They require no preparation, either by pruning the root or the top. Where the distance is not great, balls of earth may be carried with the plants, and this precaution will still further ensure their vigorous growth even during the first season.

Planting the Holly.—This is accomplished by setting the line, and opening a straight trench or furrow with the spade, as recommended for the Hawthorn. In this trench the plants should be set upright and close to the side of the trench, so that a straight line may be formed by them. The distance between the plants should be at least a foot, and, in cases where they are very bushy, 15 inches apart will be close enough. They should be planted about half-an-inch deeper than they stood before, and the soil, laid immediately to their roots, should, if possible, be pulverised. In order that they may stand firm and upright, they should be trod gently immediately after the roots are covered, and, during this operation, the best opportunity presents itself for adjusting such of

the plants as do not fall in exactly to the straight line. By taking hold of the top and treading the root at the same time, any plant may be easily made to assume its proper position.

Pruning and After-management.—For the first two seasons the hedge will require no pruning, but, after the third year, such parts of the sides as become broad and irregular had better be clipped into uniformity. I say clipped, meaning by the hedge shears, for the Holly is too thick, and its leaves too numerous, to allow of its being trimmed with a hedge-bill. I have been long anxious for such an opportunity as the present to enforce the necessity of taking the management of fences out of the hands of ignorant, though well-meaning, labourers, who have little idea of beauty and order, and who are very unfit to perform the nice operation of managing hedges. But the question is, who else are to look after them? Gardeners are not always on the spot, and even if they were, a great many of them are void of education on this head, and, I may add, as careless as labourers. A Holly hedge is considered at maturity when it reaches the height of 6 feet, beyond which it should not be allowed to grow, unless in special cases; for, if higher, the expense of clipping is very much increased. It should be perfectly straight, broad at bottom, and gradually tapering to the top, somewhat in the shape of a narrow letter A. The time for clipping is October, and it is not necessary that this should be performed oftener than once every year.

Cleaning.—This is all-important in hedge fencing, as it is in every other department of agriculture. Hedge fences are too often nurseries for weeds, which are allowed to ripen their seeds, ready at all seasons to be disseminated throughout the adjacent fields. I need scarcely add that the soil, of itself, will no more produce weeds than it will in like way produce foreign timber trees, so that, if every one would be careful to cut them off before they got to maturity, we should have much less labour and trouble in cleaning. Not one man in twenty understands what it is to hoe and rake the ground in perfection, for, according to the present practice of those who presumptuously call themselves gardeners, at least one fourth part of the weeds are allowed to remain untouched, and very generally to ripen and disseminate their seeds. Holly hedges are much easier to keep free from weeds than any other sort of fence, on account of the plants growing so close to the surface of the soil, and thus choking the herbage. Few or no weeds will be found under the hedge, but the outsides should, of course, be kept as clean as that part which is shaded by the branches. Under ordinary circumstances, the hoeing and raking would not be required oftener than three times during a season, viz., in May, July, and September; but, during wet summers, favourable to the growth of weeds, an additional cleaning would be required.

Mode of Growing the Young Plants.—I annex the nursery culture of this tree on account of its being comparatively an expensive plant to procure of nurserymen. I do this in order that every person may rear the plant for himself. It is known to everyone that the Holly is a most plentiful bearer of seed, being in most seasons literally clad with beautiful scarlet berries which, with the branch, are generally called "Christmas." These berries are perfectly ripe in November and December, when they should be gathered, and after being mixed with sand, laid in a pit in open ground till the December following; that is, for twelve months, when they should be sown during open weather. When in the pit, they should be turned over frequently so as to hasten the rotting of the pulp in which they are encased. The soil in which they are sown should be free sandy loam, shaded if possible from the south, so that the sun may not dry up the beds. For the sake of weeding them conveniently, those beds should not be more than 4 or 4½ feet wide, the soil should be made soft and fine by raking it, and the depth to which they should be covered is from a quarter to half an inch. I do not approve of sowing the seeds immediately after their being gathered, because, first, there is the loss of one year of the soil which they occupy; second, there is the cleaning of the space for a like period; and thirdly, the soil lying undisturbed so long gets so firm as to materially hinder the growth of the tender plants when they do appear. The young plants will begin to spring in May and June, and should be kept perfectly free from weeds. At the end of the second season, during the months of November and December, the plants should be removed into lines about a foot distant from each other, and the plants placed about 4 inches apart. Here they should remain for two years, when they should be again removed into lines 18 inches apart, and the plants placed about 6 inches from each other; in those lines they are to remain for a similar period. The plants will now be six years old, and if they have grown freely, they will be fit in another year to take their place as fence plants. With this view, therefore, they should be again removed into lines 20 inches or 2 feet apart, and placed in those lines about a foot distant from each other, here to remain, as stated, for one year. When lifted, such

plants will have large bushy roots, and nothing but the grossest carelessness will prevent them from forming in a short time a beautiful and durable fence.

The Beech.

This tree grows rapidly on all prepared soils, and forms a very beautiful fence. In rich soil, it retains a great proportion of its leaves in a withered state during winter; and is, on this account, excellent for nursing early Grass on such lands as are set apart for feeding and fattening different kinds of live stock. Its only defect is a want of that rigidity so striking in the Whitethorn and Crab; hence it cannot in all cases be safely trusted where cattle are grazing, unless it be protected by a ditch next to the field where they usually are. This circumstance, however, is capable of being turned to good account in soils naturally too damp for it, where a ditch would be required as well for the drainage of the land as for a protection to the hedge. In fencing such land, then, let a ditch be dug out on the field side as already detailed, 5 feet in width at top, 3 feet in depth, and 1 foot wide at bottom; the soil from the ditch is to be thrown over the line intended for the hedge (not as a bank on which to plant it, as is usually done, but for a fence to it), and the hedge itself is to be planted parallel with the ditch at about 9 inches from the edge of it. With regard to this tree, it may be stated that in the colder and more exposed tracts of arable and pasture lands, as well as on those which are too damp for the Hawthorn, it is better adapted than any other tree. Thus it becomes, on the one hand, a link between the Hawthorn and the Furze, and, on the other, between the Hawthorn and the Willow, Poplar, &c. In order to give a higher degree of rigidity to a Beech fence I have, in several instances, planted a double line of plants, and I have no doubt that this plan will obviate the defect alluded to, but as yet my hedges have not been long enough planted to prove this position. Between the parallel lines I leave a space of 18 inches, so that the stems of the plants, when grown up, form a sort of strong frame-work on either side, which I am persuaded no description of cattle will be able to break through. Between each plant in the lines a space of 15 inches should be left; and, as pointed out with regard to every other tree, no weeds should be allowed to rise amongst the plants or near to them. The time to clip is the month of October, and the form to which hedges of this description should be moulded is the same as that recommended in the case of the Hawthorn. From the facility with which it may be reared, its quickness of growth, and the valuable protection it affords to cattle in pasture lands, this tree certainly deserves to be planted more universally than it has hitherto been. From the nature of the young shoots, the hedge-bill cannot be advantageously employed in trimming the Beech; yet it may be remarked that no tree so well repays the expense of clipping, for during summer time it is, of all others, the most ornamental.

The Hornbeam and the Elm.

These trees are sometimes used for fences; but neither of them has anything to recommend them in preference to the Beech. Indeed, the Hornbeam is, in many respects, so like the Beech that, at a distance, it is often mistaken for it. One consideration in favour of the Beech over both these trees is, that nurserymen sell the plants at a few shillings less per thousand than they charge for Hornbeam, and at a considerably less price than what is demanded for Elm. —*Journal of the Royal Horticultural Society.*

Cowan's Heating Apparatus.—A number of gentlemen, at the invitation of Messrs. Trench and Murray, of Trafalgar Square, visited Hatfield, the seat of the Marquis of Salisbury, on Friday last, to inspect the system for heating hothouses, Vineries, and large ranges of buildings generally, with which our readers are already familiar. Mr. Bennett, the gardener at Hatfield, spoke enthusiastically of the plan, and stated that he heats twenty-one houses by it at less cost than nine are heated in another part of the grounds in the old manner. A number of questions were asked by gentlemen present, and explanations given by Mr. Cowan; and the general opinion expressed was entirely in favour of the new method. It was mentioned at the luncheon which followed the inspection that a company will probably be formed for purchasing and working the patent. Our own opinion is strongly in favour of the system, and so is that of many others; nor is it any wonder that this is the case, considering that a good many large ranges are effectively heated by it already. If such is the case in the infancy of the system, we may expect even more remarkable results by and bye. Mr. Cowan is already manufacturing boilers proved to produce a better result than those hitherto used, and we entertain no doubt that there is a great future for Cowan's system, provided the new company secures the inventor's assistance permanently. This system of heating will have many applications apart from its horticultural uses.

WORK FOR THE WEEK.

Flower Garden and Pleasure Ground.

THIS season, the month of May has certainly been uncertain, a registering thermometer, on the night of the 16th, having indicated 8° of frost; while, on the 20th, there were 2°—facts which afford sufficient evidence of the danger of putting out tender plants until something like a decided change has taken place; this desideratum appeared to be, to some extent, realised on the 23rd, when the wind changed from north-east to south-west, accompanied by a slight fall of rain and a considerable increase of temperature. In some situations, the soil of the flower-beds will be found to be in so desiccated a condition as to render planting, as yet, impracticable; but where, fortunately, this is not the case, no further delay should take place in furnishing beds with plants, as it must be borne in mind that the season for floral display in the open air is necessarily of short duration; and, on this account, it is also necessary to plant tolerably thick, in order that the beds may become, as soon as possible, effective. Immense numbers of plants are, consequently, required for this purpose. So much, indeed, is this the case, that, in most establishments, it has become necessary to discontinue the practice of potting off separately the various species of plants used for bedding out, recourse being had to boxes, seed-pans, &c.; and most varieties appear to succeed equally well, when turned out of such boxes and store-pans, as when turned out of small pots. Amongst plants which it is quite unnecessary to pot off separately, may be mentioned the various varieties of *Calceolarias* which should be struck during the month of October in store pots, well drained and filled with soil composed of river-sand and leaf-mould, and placed in a cold pit or frame, which should be kept close until the cuttings have become fairly rooted, when, being nearly hardy, they may be planted out in a trench or in a turf pit, so that they can be protected during severe weather, and they will generally be found to be in a fit state to move into the flower beds or borders by the middle of May. Spring-struck cuttings of *Verbenas*, *Ageratums*, *Coleuses*, *Iresines*, *Alternantheras*, &c., should also be shaken from the store-pots, and at once planted in the beds and borders where they may be required; but, in all instances, spring-struck cuttings are best. In all cases, however, water liberally as the planting proceeds, and this must be repeated more or less frequently, in accordance with the state of the weather. Keep a few plants of each of the sorts used in pots or store-pans in order to be in readiness to replace failures, which may occasionally occur even under the best management. A few plants of the various sorts of *Tricolor* and other *Pelargoniums* which may be employed as bedders, and which are not of rapid growth, should be planted out in the reserve garden in order to furnish cuttings for the following season, and to obviate the necessity of taking cuttings from beds before they can well be spared for that purpose. In many instances, *Roses* are suffering severely from the attacks of aphides and leaf-rolling caterpillars. The latter should be carefully picked off and destroyed, or the leaves containing them should be pressed, so as to crush the pests to death; whilst diluted tobacco-water should be used to syringe the plants infested with aphides, or they may be well dusted with Pooley's tobacco-powder in the evening, and syringed with rain-water the following morning. Plantations of *Roses* should also be liberally watered and mulched with good half-rotted manure, more particularly those plants which have been recently removed. Remove seed-pods from *Rhododendrons* and other American plants, the blooms of which, on account of the great drought which has, in many localities, been experienced, have faded sooner than usual this season; and, by attending early to this matter, increased strength will be given to the plants, to enable them to make growth for the following year. They ought also now to have a thorough flooding of water, and valuable specimens may afterwards be mulched, in order to enable the soil to retain moisture; for mulching, the mowings of the lawn, &c., offer a suitable material. Many Coniferous and other ornamental trees have this season suffered severely from the effects of recent frosts, and a very destructive maggot also inflicts, about this time, serious injury upon the tender shoots of the *Pinus insignis*, *P. Nordmanniana*, *Douglas Fir*, and other Conifers. This should, therefore, be carefully looked for and destroyed. Squirrels are also exceedingly destructive to all the *Pinus* tribe. The present season affords no excuse for weeds on gravel walks and drives, and advantage should be taken of heavy rainfalls to apply a heavy roller on the following day, as few things can add more to the beauty, or make gardens and pleasure grounds more thoroughly enjoyable than clean, firm, dry, and level walks.—P. GRIEVE, *Culford Gardens*.

Hardy Flowers.

Hardy annuals, if coming up too thickly, will now require thinning, and perennials sown in the open border should likewise receive

attention in this way, taking care in the case of choice kinds to re-plant the thinnings. Specimens of herbaceous plants in pots should not be allowed to suffer from want of water, and they should receive attention in the way of staking and removing dead blooms. Any seeds of perennials unsown should now be either sown in pots or in the open ground. See to the staking of border plants, and, if desirable, in particular cases, to form perfect specimens, this is best attained by judicious thinning—a remark specially applicable to such plants as *Helianthus rigidus* and *orgalis*, some *Delphiniums*, *Asters*, *Achilleas*, *Tanacetum crispum*, &c. Many perennials used for spring-bedding, such as *Myosotis dissitiflora*, *Cheiranthuses*, *Daisies*, *Primroses*, and *Pansies*, will now have to be removed to make room for the summer occupants of the beds; and in doing so the stock should, if necessary, be increased by dividing the tufts, while of such plants as the *Iberises*, *Double Wallflowers*, *Alyssum spinosum* and sextile cuttings should be inserted in sandy soil on a north border, and, if comeatable, they may be covered with a handlight, to facilitate rooting. The most attractive hardy plants in bloom during the past week have been the *Oriental Poppy*, the large scarlet blooms of which are highly conspicuous, various kinds of *Iris*, notably the dwarf *I. cristata*, of which I have seen fine specimens blooming profusely both on a warm border and in pots. The white blooms of the *Florentine Iris* are also just now conspicuous in most gardens, and so are the scarlet flowers of *Geum chilense*; *Czackia Liliastrum* is also producing its delicate white blooms somewhat freely; *Jacob's Ladder* (*Polemonium caeruleum*) and its varieties, are likewise at present nicely in flower; and I noticed a distinct dwarf species, called *Polemonium humile*, with lilac-blue flowers, which promises to be a useful plant for rock-work or front margins of mixed borders. A very pretty dwarf hardy bulb, called *Hyacinthus amethystinus*, is just now in perfection. The fine and continuous-blooming *Erodium Manescavi*, is also in flower, but this, like many other plants, is not blooming so freely this season as usual.—T. SPANSWICK.

The Kitchen Garden.

The rainfall during the last six months has been much under the average, but the land has never been in a more workable or healthier condition for growing crops than at present, neither is there now any lack of moisture. The loose friable texture of the surface has, in the absence of heavy rains, acted as a check upon evaporation; and the soil, consequently, remains in a moist condition, although no great amount of rain has fallen in this neighbourhood, at least for months. The advantages to be derived from a frequent stirring or aëration of the soil cannot be overrated. The hoe at this season is the most useful implement in the garden; its frequent use not only renders watering less necessary in dry weather, but destroys, almost in the germ, the annual weeds which are always ready to spring into active growth, and which, if neglected even for a short time, give so much trouble to eradicate. Vegetable seeds of all kinds have never germinated better than they have done this season; and, as a consequence, it is more than usually necessary that thinning should be timely attended to. I believe, however, that it is a mistake to thin out any crop all at once; for, in our changeable climate, singling out plants that have previously stood thickly is calculated to give too great a check to the growth. Root crops, such as *Carrots* and *Parsnips*, should have their drills hoed through at short intervals, leaving the plants standing in little patches. The final singling is best done in showery weather, or just before rain is expected, so as to settle the young plants that are left for a crop in their position. As a rule, medium-sized roots are more esteemed, in private establishments, than large coarse ones; therefore, severe thinning is hardly necessary, unless very large roots are required for some special purpose. About 6 inches in the row may be taken as giving a fair space for development in the case of *Carrots*, *Chicory*, *Salsafy*, and *Scorzonera*; 8 inches for *Parsnips*, *Beet*, and *Turnips*; and 4 inches for *Onions* (I am assuming that in no case are the drills less than a foot apart); whilst *Carrots* and *Parsnips* should have 15 inches. A good sowing of *Walcheren* and *Veitch's Autumn Giant Cauliflower* should now be made without delay, if not already done, for autumn use. If the land is very dry, the drills may be soaked with water before sowing the seeds, and then covered with light rich soil. Having a somewhat difficult soil to manage, I have for years made up, in the winter, a heap of compost, in which burn earth largely predominates, for the purpose of covering small seeds and so satisfied am I of its advantages, that I intend never again to be without it. The young plants are more vigorous, and less liable to be attacked by the fly. Cauliflowers that are now ready to plant out should have a cool position, where the land has been well-worked and manured; plant in deep drills or trenches and mulch with manure. *Tomatoes*, that have been standing under temporary shelter, should now, even in late backward districts, be planted out. Vacant spaces on south walls should first be filled up, but, as the demand for *Tomatoes* is increasing, all bare places on east

THE GARDEN.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE NEW SCHOOL OF HORTICULTURE AT VERSAILLES.

THE famous and once Imperial kitchen garden at Versailles is at last turned into a school of gardening. It is the most suitable spot that could have been obtained about Paris for the purpose, the scheme seems to have been carefully considered, and, in all ways, worthy of success. Recently, on visiting some of the pleasantest suburbs round Paris, and those which only a few seasons ago presented scenes of what seemed irreparable desolation, we were agreeably surprised at the great change that had taken place for the better; not only were traces of the destruction wrought by the war unseen, but the gardens and fields looked better cultivated and better kept than they were before the war. And now, disorganised as the country is in the struggle for a stable government, it is gratifying to see such minute attention bestowed on the new school of gardening. The programme of this excellent national institution has just been published, and reads as follows:—The School of Horticulture, established in the Royal Kitchen Garden of Versailles, is placed under the jurisdiction of the Minister of Agriculture and Commerce. Only out-pupils are admitted; the instruction given is entirely gratuitous; and the course of study continues for three years.

Conditions of Admission.—The candidates must not be less than seventeen, or more than twenty-seven, years old at the time of entrance. Applications for admission, drawn up on stamped paper, should be addressed to the Minister of Agriculture and Commerce, so that he may receive them by the 20th of September, at the latest. No notice will be taken of any application sent in after that date. Each application must be accompanied by (1) a certificate of the candidate's birth, as a native of France; (2) a certificate of good character, signed by the local authorities; (3) a medical certificate, to the effect that the candidate is sufficiently strong and healthy to undertake the occupation of a gardener. On receipt of these documents, which should be legally drawn up, the Minister, if everything is satisfactory, will authorise the candidate to present himself for an examination, of which he will send him due notice.

Entrance Examination.—Every candidate must undergo an entrance examination in the following elementary subjects:—(1) Reading; (2) writing and spelling (from dictation); (3) numeration, and the first four rules of arithmetic. Credit will be given to the candidates for any technical knowledge which they may possess. This examination will be held in the school on the 1st October, which is the date fixed for the commencement of the academical year, and the entrance of pupils. Every candidate who shall pass this examination in a satisfactory manner, is at once placed on the list of pupils, and has, thenceforth, right of entrance into the school.

Course of Instruction.—The main object of the course of instruction pursued in the School of Horticulture at Versailles is to train up skilled and intelligent gardeners, possessing all the theoretical and practical knowledge that is necessary in horticultural operations. It embraces the following subjects:—(1) The cultivation of fruit-trees in the open air and under glass; pomology; (2) the cultivation of forest and ornamental trees, comprising nursery work in general; (3) the cultivation of vegetables in the open air, and by forcing; (4) the cultivation of flowering plants, in the open air and under glass; (5) elementary and descriptive botany; (6) the principles of landscape-gardening and garden architecture; (7) elementary instruction in physics, meteorology, chemistry, geology, and mineralogy, as applied to horticulture; (8) the elements of zoology and entomology, in their relation to horticulture and arboriculture; (9) arithmetic and geometry, applied to gardening purposes, such as the measuring of surfaces, finding cubic contents, laying down plans to scale, &c.; (10) line drawing, and sketching plants and implements; (11) lessons in the French language and book-keeping. The practical instruction is supplied in a systematic course of manual labour, which embraces every operation of gardening. The time is so divided between these two branches of instruction, that all the pupils will take part in the work of the garden every day, and thereby acquire the knowledge and manual dexterity which are so indispensable. In addition to the instruction imparted in the school, the pupils will be taken

from time to time to visit the principal horticultural establishments, in order to familiarise them with the best examples of practical horticulture and arboriculture.

Examinations at the end of the year and on leaving the school.—At the end of every academical year, a general examination will take place for the purpose of classifying the pupils. Those who fail to pass, through this examination, into a higher division, will cease to be members of the school. Those pupils who pass a satisfactory examination on leaving the school, will receive, on the recommendation of the examiners, a certificate of merit from the Minister of Agriculture and Commerce. Moreover, those pupils who distinguish themselves most at the final examination, may (if their acquirements, and fitness in other respects, point them out as deserving of the favour) receive an appointment, for one year's practice, in one of the leading French or foreign horticultural establishments. An allowance of 1,200 francs (£48) is attached to each of these appointments, the number of which is not to exceed three every year. It must be understood, however, that these appointments cannot be claimed as a right by those pupils who come out among the first at the final examination. A nomination to one of them will depend on whether the examiners have formed a judgment of the pupil, in the course of the examination, as to whether he is a person likely to make a good use of this complementary means of improvement; preference being given to those pupils who manifest a desire for further knowledge, and an earnest devotion to their profession.

Bursaries.—Bursaries, six in number, and each of the value of 600 francs (£24), will be annually given to those pupils whose names stand first on the entrance-list, to help to defray their expenses while they remain at Versailles. Holders of these bursaries will receive them in monthly payments of 50 francs (£2). The institution will also receive pupils sent from the departments, towns, and agricultural or horticultural associations, whose expenses are defrayed by the department, town, or association to which they belong. All the pupils, whether holders of bursaries or not, go through the same course of study, practical work, and examinations, and are amenable to the same internal regulations. In the school, all the pupils stand on the same footing, and are subject to the same rules.

Discipline.—Special rules are framed for regulating the hours of attendance in the school, the employment of time, the course of out-door operations, and the maintenance of order in the establishment. To each rule is appended the penalty incurred by its infringement. Every year, the course of theoretical instruction is suspended for two months (from August 1 to October 1). During this time, leave of absence may be granted to those pupils who ask for it; but the director has the power of limiting the periods of absence, or refusing them altogether, in order to enable him to have always a sufficient number of hands to keep the gardens in order, or to carry out any works of importance or urgency. Any pupil, who does not return at the expiration of his leave of absence, is looked upon as having left the school; his name is erased from the roll, and cannot be replaced without the sanction of the Minister of Agriculture and Commerce.

THE SPECTATOR ON HINCKSEY AND ON GARDENERS.

"THEY (the students) might just as well dig their poor neighbours' gardens, or mend worn-out roads, as do anything else, and thus find out what manual labour is like, besides helping to spread æsthetic tastes, which Mr. Ruskin, with, we fear, a little too much sanguineness, holds to be of a civilising kind. Gardeners, we sometimes fear, are just as little civilised as any other labourers, though they do produce and admire flowers, and get some vague notions of colour—say, about half as accurate as those of a Turkish weaver or Japanese potter, or Cashmere shawl seller—and a conceit with which their is nothing, thank God! on this earth to compare. Talk of the vanity of a poet, or a certificated schoolmaster, or a farmer of Tennyson's sketching, they are humble men compared with a gardener who has raised a new plant, or done anything in the least noteworthy in the way of Orchids, or won a prize at the county flower-show. He feels as if he had made the plants, and wonders, not always inaudibly, why Providence was so stupid as not to consult him before Eden, with its muddle of climates, was finally laid out. Whether flower-growing and road-making, however, civilise or not, Mr. Ruskin thinks they do, and has pressed his view of them with such zeal and energy that he has found followers, and actually induced a few of the undergraduates, with springy spines and good lungs and strong wrists, and some vague sense of the enthusiasm of humanity, to dig hard in poor people's gardens just outside Oxford, and re-cut a convenient, but neglected, road, and do a good turn at once to their neighbours and themselves."

NOTES OF THE WEEK.

— IN the York nurseries, the great Siberian Lady's-Slipper (*Cypripedium macranthum*) has recently been finely in flower. It has large self purple-crimson blossoms, and, being perfectly hardy, promises to be a grand addition to Lady's-Slippers. Hitherto, all attempts to cultivate it have proved almost universally failures.

— WE have received from the Rev. Mr. Ellacombe a bloom of *Glossocomia ovata*, taken from a plant of this Bellwort, now in blossom at Bitton. It is a hardy downy perennial, a native of Northern India, with ovate heart-shaped leaves, and bell-like flowers, more singular than beautiful, which emit a peculiar odour.

— THE Court of Queen's Bench has decided that green Tea, "faced" or painted with gypsum and Prussian blue, even though the operation be done in China, is adulterated; and that persons selling such Tea are committing an offence within the meaning of the statute.

— THE *Botanical Magazine* for this month, contains in addition to *Lessertia perennans*, a purple-flowered African Leguminous plant, *Grevillea fasciculata*, *Calanthe curculigoides*, and *Saxifraga florulenta*; a good representation of *Crocus cancellatus*, a native of Greece and Asia Minor. Its bulbs are coated with coarse network in such a way as to distinguish it from most other kinds of *Crocus*, and the flowers, which are white, slightly streaked with reddish-purple, are large and striking.

— AMONGST *Gentians* grown in Messrs. Backhouse's nurseries at York, *G. verna* has produced 2,000 blossoms simultaneously—a magnificent "sheet" of dazzling blue. *G. imbricata* has also flowered. *G. pyrenaica* is now in bloom; the blossoms being vivid purple—a rare and perhaps unique exception in colour in this genus. *G. bavarica*, darker than *verna*, and, if possible, more brilliant, is now both in flower and bud. The rare *G. Froelichii*, with sky-blue flowers, like those of *G. Pneumonanthe*, but in dwarf tufts, is progressing, as is also the white variety of *G. acaulis*.

— MR. PRINCE, of the Observatory, Crowborough, Tunbridge Wells, states, that upon reference to his meteorological journal for the last thirty years, he does not find any record of such a continuance of frosts in May as in the present season. Vegetation has consequently suffered severely. The young foliage of the Oak, Ash, Chestnut, Hazel, Sycamore, and even the Bramble, has been very much injured. The Potato haulm is cut down to the ground, and at least half of the crop of Cherries, Plums, Pears, and Gooseberries has been destroyed, as well as the leading shoots of out-door Vines.

— AT a special court of Common Council, held the other day at Guildhall, the Chairman of the Markets Committee brought forward a report, recommending that the premiums of £300, £200, and £100, agreed to be given by the Court to the authors of the best designs for the proposed new fruit and vegetable market, upon the site of the old market in Farringdon-street, should be given respectively to the designs sent in under the titles of "Estelle," "Wholesale and Retail," and "Anchor." They also recommended that the sum of £50 should be given to "Plan," "Well-studied B," and "Westminster," the authors of three other plans, upon condition that the designs became the property of the Corporation. In answer to a question put by one of the members, the Chairman explained that, although these plans were accepted, the Corporation was not in any way bound to carry out either of them, but might use portions of each, as they considered most expedient. After a short discussion the report was agreed to, and the premiums ordered to be paid. Twenty-four designs had been received, and the estimated cost of the building, according to the three selected, was respectively £65,750, £88,000, and £68,890.

— *SILENE HOOKERI*, a distinct dwarf species of Catchfly, with large flesh-coloured flowers, the petals of which are finely divided, is now in blossom on the rock-work at Kew, where a strong plant of *Cyclobothra pulchella* is also producing pretty yellow flowers. Several plants of the true Alpine Forget-me-not are also nicely in bloom; and the flowers of several species of *Allium* are conspicuous, particularly those of *A. pallidum*, a low-growing kind, about 9 inches high, the white blooms of which are borne in abundance. We also noticed, too, *Onosma taurica* labelled *Anosma taurica*, a fact which shows that even at Kew botanical spelling is not always to be trusted. In the herbaceous grounds several highly interesting plants are now in bloom, notably the pretty dwarf species of *Dianthus* called *brachyanthus*, with light rose-coloured blooms, a plant alluded to by us on several previous occasions, but one which has not, so far as we have observed, yet come into commerce; a nice tuft of *Geranium subcaulescens*, with pretty blooms of a fleshy-rose colour; and *Orobis atropurpureus*, an old species too seldom seen. The true Official Rhubarb is also in flower, but its value as a decorative plant consists in its distinct-looking noble foliage rather than its flowers. Some *Ferulas*, planted out in a bed near the museum,

appear to have received much benefit from a mulching of manure, a practice well worth attention in the case of other plants in dry seasons on light soil.

— PERHAPS the gayest perennial now in flower in the York nurseries is *Lithospermum Gastoni*. Imagine masses of from fifty to one hundred stems, from 4 to 8 inches high, forming a tuft only 12 to 18 inches across, and each stem bearing from three to six lovely sky-blue flowers, as large as a sixpence, and some idea may be formed of the beauty of this plant. It only shows its real character, however, when very strong, that is, after having been established some two or three years at least.

— It is expected that the forthcoming anniversary dinner of the Gardeners' Royal Benevolent Institution, which is to take place on the 2nd of July, under the presidency of Mr. Alfred De Rothschild, will be a great success. The committee, we are informed, have arranged that three persons, who have been subscribers to the charity for over fifteen years, and who have otherwise in every way complied with the regulations, should be added to the pension list this summer, without election. Other candidates, less eligible, must, therefore, wait until they can be admitted in the usual way.

— "BEDDING OUT," which, on account of the unfavourable weather, has been deferred to an unusually late period this year, has been carried on in our metropolitan parks and gardens with vigour during the past week. In the sub-tropical garden at Battersea numerous tropical plants have also been planted out, such as *Wigandias*, *Cannas*, *Aralias*, *Solanums*, &c., and already appear to have started into growth in their new quarters. Plants of *Cannas*, which have been in the beds all the winter, have also, notwithstanding the lateness of the season, attained a height of upwards of 2 feet.

— DR. MOORE, of Glasnevin, who has just returned from Florence and Vienna, has brought us some very interesting information as regards that fine plant Dampier's Glory Pea. This, as everybody knows, is a plant most difficult to cultivate to anything like a vigorous flowering condition. In the Schoenbrunn Gardens, at Vienna, he was surprised to see many plants of it, fine pyramids, 4 feet high, full of flower. These have been obtained by grafting *Clianthus Dampieri* on the old and more easily grown and vigorous *C. puniceus*. In this way the Dampier Glory Pea grows with a vigour worthy of its noble blooms. Dr. Moore was informed that plants of this *Clianthus* were a good deal used for indoor decoration.

— AT a recent meeting of the scientific committee of the Royal Horticultural Society, Dr. Voelcker stated the results of his investigation of the soil of a London square in which Messrs. Veitch had twice planted Planes, which in each case had died. He found, on examining the clear watery solution from treating the soil with distilled water, that the soil contained one-tenth per cent. of common salt, and two-tenths per cent. of nitrates. He did not doubt that it was owing to the place having been constantly used in the way of nuisances that the presence of salt and nitrates was due. In the same way rabbits kill hedges, and it is well known that it is years before Grass will grow on their runs.

— THE Society of Arts has in consideration the organisation of a series of provincial exhibitions of an industrial character, to be held in the centres of the manufacturing districts. As the proposal was only made at a meeting the other day the plan is, as yet, by no means complete, but a principal part of it seems to be that the special industries of each locality should be, as far as possible, illustrated in its exhibition. The experience of the Horticultural and Agricultural Societies, and of the British Association, goes to show that much may be hoped for from a migratory arrangement like that proposed, while there can be little doubt that such exhibitions, if properly carried out, might do a great deal in assisting the growth of that technical instruction, the absence of which is so great a hindrance to the British workman in his struggle with Continental rivals. We understand that the idea of a building suited for such exhibitions originated with Mr. Wm. E. Rendle, well known for his various inventions in horticultural buildings.

— AT a late field-meeting of the Woolhope Naturalists' Club, the effects of the late frosts upon vegetation were everywhere noticed. In low grounds, frost-bitten Cowslips were gathered; and, on heights, the sward was parched, and the culms of the short Grass blanched and dead. Even the hardy Bilberry (*Vaccinium myrtillus*) had its young leaves nipped into a browner shade than usual, and its growth stunted to little more than half its usual height—except, indeed, in a few places where the plant was sheltered by masses of rock. The Rock Bedstraw (*Galium saxatile*), which ought, at this season, to have covered the surface with its delicate white flowers, was visible only to a close search; and the only wild flowers which seemed wholly unaffected were the pretty Mountain Pansy (*Viola lutea*), the bright yellow lip of which adorned the sward wherever there was half-an-inch of soil to afford it foothold, and stunted specimens of the Dog Violet (*Viola canina*).

THE FLOWER GARDEN.

THE GREAT SPOTTED IRIS IN THE GARDEN OF THE ARCHBISHOP OF CANTERBURY.

THIS plant (*Iris susiana*) has long been one of the most interesting known to European cultivators; its blooms are among the most striking flowers in our gardens, and it was well-known and figured so long ago as the time of Parkinson, yet it has never become a commonly grown plant, and to see it in flower is a rarity. The reason of this has always seemed to us to be the fact of its being somewhat difficult to cultivate. We supposed it to be somewhat tender, and it is usually grown in a frame or pit, or greenhouse. Even treated thus, however, it is usually a delicate-growing subject, and seldom flowers. Its fate eventually, is usually to be forgotten and neglected, and, finally, to disappear from the garden altogether. We had several times tried to establish it under hand-lights in warm borders, but always failed to cause a healthy growth. Looking round the Archbishop of Canterbury's garden, at Stonehouse, a few weeks ago, we saw some wide-spreading and healthy tufts of Iris, with here and there a blackish-looking bud, seemingly different in aspect from Irises usually grown in borders, and, on examination, these proved to be tufts of our old friend *Iris susiana*! Last week we received fully expanded blooms, the largest we have seen—a single flower being three times the size of that depicted in the annexed illustration. A non-botanical member of our staff at first sight mistook the quaint and huge blossom for a bonnet! This plant has been grown for a good many years at Stonehouse as a common border flower, receiving no more attention than do the masses of German Iris in cottage gardens. The soil is chalky, and the situation very near the sea, but by no means so favourable for vegetation as many other parts of England. The important fact then, to bear in mind is, that *Iris susiana* may be treated as a perfectly hardy plant in many parts of the country, as well as the Isle of Thanet; a dry bottom and free soil are, no doubt, essential to success. The fact that this species may be grown in the open air with the many others that are now obtainable, is another reason for growing Irises more frequently. Lilies have become very popular of late; the Irises deserve to be equally so, for they are the noblest hardy flowers of the early summer. Many superb kinds are never seen in our gardens, though as easily grown as the common German kinds now in

blossom in London back-gardens. The best way to grow a choice selection in a garden of any size, is in a large isolated bed, oval or circular in outline. It should be rich and open in texture, and well drained for the sake of a few of the more delicate species; most of the kinds grow freely enough in stiff coldish soil. The plants vary in size from *I. pallida* and *I. ochroleuca*, 3 or 4 feet high, down to some not half-a-foot high, as *I. cristata*. They vary strikingly in colour and markings too, so that an attraction of no mean order is a well-planted and well-arranged mass of Irises alone. A few of the finer Lilies, however, may be placed among them with good effect, and round the margins, in early spring, bulbous flowers may be dotted. W. R.

The great Spotted Iris (one-third the natural size).

SAXIFRAGES.

By J. C. NIVEN.

The None-so-Pretty Group.

WHEN I entered upon the task of analysing the Mossy section—which I completed in my last article (see p. 419)—I was sanguine enough to think that, having so far progressed, I should have got through the most difficult part of my subject. Here, however, when I contemplate the array of species and varieties which naturally associate themselves together under the old-fashioned title which I have given above, I find confusion quite as predominant in this as in the Mossy group; true, their numbers are less, but in this respect only is my task lighter.

The None-so-Pretty, or London Pride, is a plant familiar to all from childhood; what happy associations connected with the morning of life and first attempts at posy-making, the very mention of the name calls to mind; it is so, at least with me, and no doubt will be the same with many of my readers. It seems almost too bad, after the above charming title, to even hint that the classical term applied to this group is Robertsonia, and that along with it I purpose allying the *Miscopetalum* section, which Engler, owing to some minute structural peculiarity, has banished

to a far-removed part of his "Monograph;" and, by way of a stepping-stone from my last section—which, in outward appearances, presents such a striking dissimilarity—I will import the old meadow Saxifrage, in the granulated fleshy roots of which, as well as in the power of producing axillary buds, we have, if not a sort of relationship, at least a pretty close analogy to those bud-bearing species, which I enumerated at the close of my last article as peculiar to Southern Spain and Northern Africa.

S. granulata of Linnæus is a thorough lowland representative of the Saxifrages, a native of Britain, and by no means rare; it will

be familiar to many of my readers in its wild state. It is generally met with along the marginal line between woods and meadows, where it appears thoroughly to enjoy the partial shade of the trees, and also the root shelter of the adjacent herbage. Its lower leaves are reniform and deeply lobed. It is in the axils of the first formed radical leaves that the granulated buds or bulbils are formed, and wonderfully pretty they are with their blunt fleshy coral-like scales. The stem rises to a height of 12 to 15 inches. The flowers are large and scattered, and have very much the aspect of those of the previous group, supported, however, on more erect and sturdy stalks.

S. granulata fl. pl.—The only instance, within my knowledge, of real duplication that occurs in the genus; exceptionally, we meet with ten petals in place of five, but here we have a perfectly double flower, pure white, formed of a dense mass of petals, added to which the arrangement of the flowers in the inflorescence is far more compact than in the single form, and the whole habit of the plant is dwarfer. What its origin is I cannot discover, nor is there, I believe, any record of its having been met with wild; be this as it may, it is a most desirable plant for garden culture, and by no means as frequently seen in the front rank of the herbaceous border as it ought to be. There is also a variegated form of *granulata*, but so undecided and evanescent is the variegation that the mere mention of the fact will suffice.

S. bulbifera of Linnæus, as a species, claims a very close relationship to the preceding, but differs, first, in the general development of the plant being on a smaller scale, and second, in the bulbils being formed in the axils of the leaves above the ground, even in the leafy bracts of the stem; again, it affects mountains rather than meadows. This species may be at the present time in cultivation, but I have not seen it for years. It is a native of Sicily, Corsica, and Sardinia, and also the Carpathian Mountains; it is by no means either so beautiful or permanent a plant as its granulated congener, the less permanent character originating from the fact that the plant is liable to die off before the bulbils have reached sufficient maturity to retain their vitality for another season.

S. rotundifolia enjoys a good old Linnæan and most appropriate specific title, the round-leaved Saxifrage. By the casual observer the leaves would be at once pronounced round, but, really they are reniform, the lower ones supported on long hairy stalks, the margins are irregularly notched, those on the stem are almost lobed; the inflorescence is a leafy branching cyme, rising to a height of 12 inches; the flowers are white, dotted over on the inner surface with minute pink spots, so minute that they are unobservable at a distance, but charming in their exquisite delicacy, when the flower is closely examined. This, and the succeeding species, are distinguished from those in both the Crustaceous and Mossy sections, by an important structural peculiarity, in the fact that the ovary is superior, a distinction, whose value my botanical readers will readily understand; geographically speaking, this species appears to enjoy a wide range in South Europe, and also in Asia Minor. It is a free grower in any ordinary garden soil, where it forms dense compact tufts of a good perennial character.

S. rotundifolia var. reniformis has, as the name at once indicates, more markedly reniform leaves than the typical plant; it is also a stronger grower, and appears to be very partial to moisture. In the flowers, no special distinction is noticeable—so far, at least, as I have been able to detect; but the plant is altogether more hairy, and has a sufficiently distinct aspect to retain it as a variety, though certainly not to raise it to the specific rank which we sometimes find assigned to it.

S. repanda of Willdenow is by Engler recognised only as a variation of *rotundifolia*. Here, I think, Willdenow's older name is well worthy of being retained in its specific entirety. The leaves are double, and sometimes treble, the diameter of the round-leaved Saxifrage, of a thick fleshy substance; the marginal notches are obtuse and blunt-pointed; the flowering stems are foliaceous, much branched, many-flowered, and rise to a height of 2 feet, or even more, thus giving, in their giant stature, associated with the large fleshy leaves, quite a distinct contour to the plant; added to which, the entire surface, including both stem and leaves, is suffused with long hairs; the flowers are larger, and the pink markings are more conspicuous. It is a native of southern Italy, Sicily, Greece, and the Caucasus, where it abounds in the low mountain valleys.

S. angulosa of Schott—referred, also, by Engler, to the round-leaved form—is a very distinct-looking plant; its leaves are somewhat obliquely reniform, the margins indented with irregular rounded crenatures; it is dwarfer in growth, and more slender, as well as constitutionally more delicate, than any of the preceding. It has not yet flowered with me; so, in retaining its specific identity, I am guided by the general appearance and habit of the plant.

S. taygetea of Boissier possesses such individuality of character, that it is simply astonishing that Engler, in place of merging it into

a mere form of our typical species, did not for once in a way break through the rules respecting nomenclature, and give it the characteristic title of *soldanellæfolia*; Boissier's name, under many orthographical variations, having now been recognised for some time, I have retained it, and may here state that it means the Saxifrage of Mount Taygetos, one of the old classical hill tops of the Peloponnesus. Our plant is a dwarf compact grower, the leaves small, quite round, glabrous and fleshy, and supported on long foot-stalks, the margin undivided and perfectly smooth; the flower-stem is leafless, about 5 or 6 inches high, unbranched, except at the summit; the flowers have broader petals than any of the previous species; the markings almost altogether absent, and each individual petal is concave. As a species, I feel sure all who cultivate it will agree with me that it is essentially distinct, and well deserving a more characteristic name than it possesses.

S. umbrosa of Linnæus.—This is, undoubtedly, the gentian None-so-Pretty or London Pride; the former name originating in the charming simplicity of its flowers, and the latter in its power to grow and flourish under the adverse circumstances which the smoky atmosphere of London, and, indeed, all our large cities present. Often have I stopped to admire great patches of it growing luxuriantly under circumstances so unfavourable that even the ordinary weeds had died out and left it in its proud position as complete master of the situation. One special attribute it has, is that years will elapse before it shows any indication of having exhausted the soil; and another is that, growing naturally—as its specific name indicates—in shady localities, it will thrive better in a north aspect, where no direct ray of sunshine penetrates, than it will on a warm sunny bank. To give a detailed description of a plant so well known would be a complete waste of space. I must, however, point out one important character that distinguishes it from another species, *S. Geum*, with which it is very often confused, and to which it is very closely allied; in *umbrosa*, the leaves are broadly oval, gradually tapering into the foot-stalk, and devoid of hairs. It is a native of Ireland, where it grows abundantly, especially in the southern districts; it is also found in England and Scotland, but is both local and rare. The only other recorded localities is the south of Spain and, strange enough, the north of Africa. Possibly, being such a common plant, collectors have passed it over as not worth taking; hence, its limited representation in our large Saxifrage herbaria.

S. umbrosa var. serratifolia, sometimes also called *Melvillii* and *acanthifolia* is a form in which the margins of the leaves are much more deeply indented than those of the old typical plant; further, they retain the same character very constantly in cultivation.

S. umbrosa var. Oglevieana is an especially distinct form that I have cultivated for years, in fact, so long that I cannot remember the source whence I obtained it; it is a compact grower. The leaves are narrow, very irregularly and deeply notched; the margins incurved, and remarkable for the broad light-coloured midrib, which, being about the same width as the blade portion at each side, gives a distinct variegated appearance. The flowers are produced in dense panicles, about 8 inches high, the primary and secondary stems of the inflorescence, as well as the buds being of a beautiful red colour; the petals also are pinkish. I was under the impression at one time that this was no more than a stunted form, and, with a view to test it fairly, planted a nice tuft under most favourable conditions for a vigorous growth, but produced no change whatever. I was, however, delighted with the result in the beautiful appearance of the plant when in full bloom. I should much like to get further particulars as to its origin, and possibly some of my readers may be able to enlighten me thereon. I ought to state that I have seen it under the specific name of *Ægilops*, and, further, that no notice or description of it is given in Engler's "Monograph."

S. umbrosa variegata forms an exceedingly pretty plant, where it retains its variegation; this it does in some soils and situations with considerable constancy. Should it tend to revert back to the normal type, care should be taken to plant it in very poor soil—a corner of the rockery, filled with gravel, will answer the purpose admirably. If planted in rich garden soil, it is almost sure to revert to the green or normal state with the first season's growth.

S. Andrewsii of Harvey, would, at first sight, be readily taken as a spatulate variety of *umbrosa*. The leaves are, however, more erect and sharply notched along the margin by a series of minute cartilaginous and rigid serratures. The appearance of the plant leads one to look upon it as of hybrid origin, and this is confirmed the more when, on examining the flower, we find that the ovary is, what is technically termed, half-inferior, thus incorporating a very important structural character into this group which it does not otherwise possess. I am disposed to agree with Engler, that it is a hybrid between

lingulata and umbrosa, but how about its origin? Found by Mr. Andrews in one of the wild glens in Kerry, where no single Crustaceous Saxifrage grows; whence then could have originated the structural variation of that section. If it be a true species, how is it that it has never been found since, at least never that I have heard of? Surely it was not the very last representative of a now extinct indigenous specific type? I have, on several occasions, saved seeds of it and sown them, but was only once successful in raising three weakly seedlings, one of which only weathered the first season and died soon after; not, however, before it unmistakably showed its close relationship to the true umbrosa.

S. Andrewsii var. *Guthrieana* has shorter and narrower leaves, and more evident signs of its Crustaceous origin; it is, I believe, a seedling therefrom, that originated in the neighbourhood of Edinburgh, thus indicating the parentage more pronounced on the one side as compared with the result of my experiment, where the tendency was to revert to the other parent. There is a very beautifully variegated form of this, that, were it a freer grower, would become a most useful plant, but it is rare one sees a healthy vigorous plant of it. That these very opposite sections do hybridise the one with the other is confirmed, in the fact that I have a very interesting cross between *Cotyledon* and *umbrosa*, which shows intermediate characters between the two in every respect, except the position of the ovary, which retains, singularly enough, the character of the pistil-bearing plant.

BEDDING PLANTS WITHOUT POTS.

ALLOW me to inform your readers how I have managed to raise enough and to spare of first-class bedding plants. About the 10th of August I had everything in readiness for propagating them. All were to be inserted in boxes 12 inches wide, 36 inches long, and 9 inches deep. These were crocked, and over the crocks were put the riddlings of leaf mould, consisting of Beech nuts, &c., which made good drainage. Next was put a good layer of ordinary soil, which does well for *Pelargoniums*, *Verbenas*, *Agatheas*, and similar plants; these materials were levelled and pressed, and half-an-inch of sand was put on the surface, the whole being about half-an-inch below the edge of the box. The sand was then moistened through a rosed watering pot, giving just enough to prevent the soil filling the holes made by the dibble when inserting the cuttings. Good strong cuttings were then taken from the plants in the beds, with which a hamper was filled and carried to the propagating shed. The two lower leaves of the cuttings were then removed, as well as any blooms that happened to be on them; a clean cut was made immediately below a joint, and the cutting was ready. A good large dibble was then used for making the holes, the cuttings were inserted, the soil made firm, and a good watering given. They were placed in a shaded situation until roots were emitted, when they were fully exposed to the weather until frost began to make its appearance, when they were placed in empty Melon and Cucumber frames until the Grapes were cut from the Vines, which was about the end of November. Temporary stages were then made in the Vineries, and the boxes placed on them. Air was then admitted, both night and day, when the weather was favourable, and no fire-heat was used, except in the severest weather. Thus situated in very dry soil, they retained excellent health until the beginning of February, when they became too thick (I mean the *Pelargoniums* and *Verbenas* which we took out of the boxes); and, having only a limited supply of pots that would suit them, we treated them as follows:—We got several balls of twine, like those used by shopkeepers; also a quantity of Moss from the woods, and soil. We then took a small handful of Moss, and flattened it out on the palm of the hand; on that we put a handful of soil, and on this the plant; then a little more soil, and then tied the whole up in such a way as to keep both soil and Moss firmly round the plant. The boxes were re-filled with the “mossed plants,” retaining the drainage, of course, and putting the plants low enough to have the balls below the edges of the boxes. A layer of soil was then put over them to hide the Moss. I need hardly add that, thus treated, room could not be found for more than half the number of plants that were formerly in the boxes. Fortunately, we had a small glass-house used in the summer time for “succession plants” for the greenhouse, in which were good shelves and a good stage. Into this we put the

rest of the plants, keeping each variety to itself, and placing a little soil over the Moss to keep the balls moist. Whenever we watered them, we did so with a roseless pot, and kept all wet off the leaves. Thus situated, they grew and flourished without artificial heat until they were put out to harden, and were ultimately placed in the flower garden and borders. We left *Königa*, *Cerastium* (the latter we propagate by means of cuttings and not by division), *Agathea*, *Lobelia*, *Gnaphalium*, *Verbena venosa*, &c., in the cutting-boxes, but *Verbenas* and *Geraniums* we mossed, and with excellent results. Our *Calceolarias* we treated in a different way. In the end of September, we procured some boxes that were well drained, and filled with soil in which leaf-mould preponderated; and, on the surface, was put a layer of sand. When taking off the cuttings from the parent plants, we took good care to select such as were in good condition. They were immediately prepared and inserted in the boxes; and, having given them a liberal watering, we placed them in a shady place, and not, as some recommend, under the scorching influence of the sun. Thus situated, they remained until it was time to place them indoors, when we set them in the greenhouse just alluded to, shading them when the sun was shining brightly. About the beginning of February, they became too large for their boxes, so we prepared some frames, placing fresh leaves in the bottom of them. We then trampled them firmly down, and level. Over this, which was put in for drainage, was placed a compost of rotten leaves, well-decomposed stable or Melon dung, and a fourth-part of Melon loam; these were levelled but not trampled upon. The plants were then taken out of the boxes with as much care and with as good balls as possible, and were planted in the frames, the operation being carried on on a fine day. A hole was then made with the hand, the plant inserted, and the ball covered over with the material, pressing the whole gently and giving copious waterings. The plants remained there and were covered in frosty weather, until more room was required, when they were, indeed, in splendid condition; they were then put into frames in fresh soil, given more room; and here they remained until they were planted out the other day, when each plant would yield, without injury to itself, from eight to twelve cuttings. Everyone ought to know that a cool place is the best for *Calceolarias*, giving them a liberal supply of water, when they want it; indeed, they should never be allowed to get too dry. I hope that cultivators who have been in the habit of growing *Calceolarias* in pots in Vineries will give this mode of treatment a fair trial.

JOHN BRENNAN.

Loughgall.

New and Improved Pæonias.—Any one who is not acquainted with the numerous magnificent varieties of herbaceous Pæonias which now exist, cannot form anything like a full idea of the beauty which has been developed in this genus of hardy plants. Vulgarly is the idea which has long been associated with the effects of the Pæonia; and, as regards the old, roughly-formed, and glaring-coloured varieties, emitting odours anything but pleasant, the association may be correct, especially when such old varieties were misplaced in choice selections of plants. But there is a race of Pæonias now in cultivation which, for perfection of form and delicacy of colouring, vie with the queen of flowers herself, and many of them are sweet-scented. They embrace all the delicacy of colouring which lies between the pure white, the pale pink, the delicate blush, the brilliant rosy-purple, the crimson, and various other effective and pleasing colours. Such varieties as *Alice de Julvecourt*, which has guard petals of the most delicate pink, with the centre petals of a beautiful blush-white, slightly flaked with crimson-purple. The flowers are as double and compact as the finest rose, and the blooms of great size. Then there are such as *Léonie*, of a delicate peach, with splendidly double flowers, symmetrical in form. And there are such as *Caroline Allain*, with beautiful blush guard-petals, and the centre sulphur, tipped with white. We were more astonished with a boxful of cut blooms of these and such as these, and with a bed of them that we saw in Mr. Parker's nursery, at Tooting, London, than with any hardy plants we have ever seen; and, as they become known, predict for them great popularity. For planting in shrubbery borders, or singly or in groups in odd nooks on Grass, nothing could be more effective. They bloom from the middle of June to the end of July, and grow well in any ordinary garden soil moderately enriched with manure. They are easily increased by division. The following twenty-four varieties may be relied upon as

very effective, and combine a great variety of delicate colouring:—Alice Julvecourt, Comte de Cassy, Anthusa, Caroline Allain, Charles Binder, Beauty de Vellicante, Decandolle, Faust, Festiva maxima, Isabella Karlitzky, Jeanne d'Arc, Léonie, Madame Furtado, Madame Vilmorin, Magnificent, Monsieur de Rousselon, Madonna, Marquis de Lory, Modest Guerin, Pulcherrima, Standard de Grande, Rosamond, Sidonia, Virginie, Triumphe de Paris, Versicolor, Whiteji.—*The Gardener*.

Cure for Weeds on Walks.—Where paths are very bad, the best plan is to hoe them up, and then rake off the weeds as far as possible. Then a good dressing of salt or sulphuric acid may be given; the former thickly strewn over the surface, the latter in the proportion of 1lb. to 20lb. of water—but it ought to be prepared in a glazed earthenware pan, and the ground just wetted with it, using the rose from a watering-pot; but the acid should not touch the Grass edgings, or any plant growing by the side of the paths, as it kills wherever it touches. It not only destroys any growing weeds, but also the seeds that have not yet germinated. In a day or two afterwards well roll the walk, and it will have quite a fresh and bright appearance. In all small gardens the paths should be kept free from weeds by means of hand-weeding.—Q.

Roses for Town Gardens.—The selection of "Thirty-two Roses for Town Gardens," given in THE GARDEN (see p. 438), has afforded me much interest. I was, however, somewhat surprised to see Charles Lefebvre and Madame Victor Verdier included in the list, as, from the remarks of Mr. Reynolds Hole, in alluding to these two Roses (Vol. I. pp. 159, 251), it would appear that they are to be classed among the doubtful kinds, being delicate or variable sorts. Referring still farther to back numbers of THE GARDEN, I find that Mr. Hobday (Vol. II. p. 551), in recording his own experience, speaks very hopefully of the chances of the suburban roseist, provided the latter makes up his mind to aim rather at a selection of varieties than a collection. What does Mr. Hobday say to the list under notice, which would seem in any case to admit of a little variation in regard to colour among the Hybrid Perpetuals? Will he kindly say whether or not there would be any objection to adding the following, viz.:—*Crimson*, Senateur Vaisse, Alfred Colomb; *carmine*, Victor Verdier; *pink*, Comtesse de Chabillant, Madlle. Thérèse Levet; *blush*, Madame Rivers, Caroline de Sansal; *white*, Madlle. Bonnaire.—M. R.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Canadian Bitter Root (*Lewisia rediviva*).—Scores, if not hundreds of buds, are set on this handsome and curious hardy plant in the York nurseries, promising a grand display shortly.—J. H.

Butterworts.—Your correspondent, who is so much and justly pleased with *Pinguicula vulgaris* (the wild English Butterwort) when well grown, can scarcely fail to be delighted with *P. alpina*, which, in general appearance, closely resembles it, though rather smaller in all its parts. The flowers are white tinted with lemon colour and a trace of pink. In moist shady crevices of rock-work (not overhung with other vegetation), and in a soil composed of peat and loam, it is a very pretty object.—DELTA.

Poet's Narcissus (*Narcissus poeticus*).—This is one of the most useful of all the Narcissi, and deserves to be planted in great clumps in neglected parts of the grounds, where it will soon establish itself if left untouched by lawnmower or scythe. Its pure white sweet-scented flowers are well adapted for cutting, and come in very usefully for vases or large bouquets. There are several varieties of this Narcissus, varying in the depth of the purple or saffron rim to the flat cup, and one form has double flowers nearly as white and as fragrant as those of a Gardenia, qualities which make it a valuable addition to cut flowers.—B.

Myosotis dissitiflora.—This has flowered most luxuriantly with me this spring, producing such a mass of bright sky-blue blossoms as to be for a time literally unrivalled. I had the whole of my stock (about 2,000 plants) put out early in the winter on a south border, and they occupied about five rods of ground. One half were seedlings, the other half divided old plants; but, although these latter did fairly well, the seedlings did much better, so much so, in fact, that I shall not save old plants any more. Seed should be sown early in July, and, if properly shaded and watered for a few weeks, an abundance of strong plants will be ready in November for planting out.—A.

Primula altaica (Lehmann).—A strange error seems to be prevalent regarding this Asiatic Primula. The true plant is closely allied to our wild *P. farinosa*. It has nothing whatever to do with the wild Primrose, either in shape of leaf or blossom. It bears a head of many flowers, each about half-an-inch across, of a very pale pink or flesh colour, changing to nearly white, on stems about 6 inches high. Its leaves are narrower even than those of *P. farinosa*; narrower, perhaps, than those of any other known species of Primrose in proportion to their length, and are entire or obsoletely dentate, and taper downwards into a petiole. I greatly doubt its having ever been introduced even into Europe in a living state.—JAS. BACKHOUSE, York.

The Male Orchis as a Border and Pot Plant.—A correspondent of the *Irish Farmers' Gazette*, speaks as follows of this plant:—"I had great success this spring with Orchis mascula in pots; some of them had three and four spikes, fully 12 inches high. They were better than Hyacinths, and remained three times as long in flower; they are about the most easily managed things I know of." Is not this encouraging, and how many more even finer subjects have we at our doors, the cultivation of which would be equally easy, as, for instance, the fragrant *Gymnadenia conopsea*, with its tall purple spikes; *Orchis latifolia*, in its varied forms; *O. Morio*, the Bee Orchis; the white *Habenarias*, &c., all of which we have reason to know are capable of being wonderfully developed under cultivation.

THE FRUIT GARDEN.

STRAWBERRY CULTURE IN THE BLACK FOREST.

THE principle of association in the raising and disposal of fruit and vegetables would appear to be gaining ground in Germany. A short time ago we gave an account of the doings of an Asparagus growing company, an association of well-to-do farmers, gardeners, and landowners, in the neighbourhood of Brunswick. Again, the reader's attention is called to an instance of successful co-operation in the case of the inhabitants of a poor village. Staufenberg, the village in question, is situated between Gernsbach and Baden, in the Black Forest, and the special culture which has raised its inhabitants to their present comparatively prosperous condition is Strawberry growing for the market. Of the two hundred peasants and others who divide the neighbouring land between them, the largest occupier does not cultivate more than 8 or 9 acres, and it therefore will not surprise us to hear that 1 ton is usually about the largest quantity of Strawberries raised by any single individual. Last year, being an exceptionally fine one for Strawberries, the crop probably averaged a ton to each grower, which, at the ordinary price of 50s. to 66s.—say 58s.—the cwt., would bring him in the nice little sum of £58. From this must, of course, be deducted the rent, labour, value of manure, carriage, and expense of sale: but, even then, a handsome balance remains. The gathering has to be done either late in the evening (after sundown) or—which is the preferable time—quite early in the morning (before sunrise), otherwise the Strawberries would not arrive at their destination in a marketable state. An association, established on Schulze-Delitz principles, and consisting chiefly of the different Staufenberg growers, undertakes to forward the fruit, by train, to Frankfort-on-the-Main and other towns, and also to effect the sale of it. Only a small portion of the produce is disposed of as table fruit; by far the greater quantity is sold to confectioners and dealers in preserved fruit, and finds its way, candied or preserved, or in the form of jelly, syrup, wine, &c., to all parts of Germany. The chief sorts of Strawberry cultivated are the Large Red, the so-called Brown Italian, the common and large Annas, also—finest of all—the Cinnamon Strawberry. A northern aspect, unsuitable for many other cultures, is the one preferred for Strawberries, and land so situated in the neighbourhood of Staufenberg has, therefore, greatly risen in value. The fruit grown on southerly slopes, which ripens first, can be most profitably disposed of to retail purchasers in Baden, Rastatt, Karlsruhe, and Wilbad. At the last-named place the association has erected a handsome wooden building for the sale of its produce, and every evening during the season the forest paths leading to it from Staufenberg are frequented by a little army of fruit-carriers.—T. S., in *Field*.

Watering Pines.—Permit me to add, to what I have already said on this subject, that since I last wrote we have shifted 500 Pine suckers from small pots into fruiting ones, and that amongst them were a few which had been grown under drip. The soil about these was, therefore, much moister than that in the case of such as were more favourably situated. The balls of the moist plants were sodden and half pasty; what few roots they had were black and lifeless, while the balls of those which were not extremely dry, but sufficiently so to allow the loose soil to be rubbed off gently with the hand, leaving the rootlets prominent and ready to penetrate the new soil, were a mass of fine, fresh, white, vigorous roots. These plants will at once start into growth, and by September will have matured a fine head; they will have their pots literally filled with healthy roots, ready to rest for a couple of months, and then start into growth, and fruit early next year, with every certainty of brilliant results. The half-rooted few will be only getting into growing condition six weeks hence; by the autumn they will not be more than half developed, and, after dwindling throughout the winter, they may probably, through good treatment, be induced to fruit imperfectly about the month of August next year. The difference between wet and comparatively dry treatment will thus be apparent.—J. MUIR.

Heavy Strawberry Crop.—A market gardener located near Lawrence, Massachusetts, recently assured the *New York Tribune* that last season he sold more than 2,800 dollars' (£560) worth of Strawberries from 2 acres of ground. His method is as follows:—In the spring of the year he plants on well-prepared soil in hills 2 feet apart. The variety chosen is Wilson's Albany. The beds are kept cultivated during the season, and all runners and blossoms are carefully clipped away. The next season the crop is taken, and although the present year was in many places unfavourable for Strawberries, yet on this particular plot nearly 6,000 quarts per acre were gathered. After bearing one year, the beds are ploughed up, and other crops planted. Meanwhile other beds are coming to a bearing condition.

MR. HANBURY'S GARDEN AT LA MORTOLA,
NEAR MENTONE.

AMONG the many gardens which dot the shores of the Riviera, there is none more interesting to the lover of a varied collection of plants than this. Thoroughly sheltered on the north by mountain ranges, the district is as favourable for vegetation as any along the shores of the Mediterranean. The garden we are about to describe, and which is the happy home of a most numerous collection of plants, is perfectly protected in its greater part, but in part, also, is carried out on a little promontory into the iris-dyed sea; and hence cool and fresh breezes temper the great heat of summer. So many lovers of gardening are satisfied with a few carefully-selected kinds of plants, that it is at all times a relief to find a garden in which we see some evidence of the infinite variety of the vegetable kingdom, and some flowers other than those that come before us every day. We have never seen a garden in which the claims of variety are more fully recognised than here, or one from which we derived more pleasure and instruction. The first objects which struck our attention here (as one might be struck by seeing Tree Ferns in an Essex marsh) were some magnificent blooming specimens belonging to an order which we generally know in its most humble representatives, the Borage tribe. These were the

Giant Echiums,

plants which seem to be of the highest importance to cultivators, as possessing beauty in a high degree, and being, withal, utterly distinct in aspect from anything we now cultivate under glass or out of doors. Among the various tribes of hardy flowers that adorn our gardens, none are more attractive to the lover of plants than the Borage or Forget-me-not Order. By the stream-side (home of the common Forget-me-not), in the wood, where the blue of the wood Forget-me-not (*Myosotis sylvatica*) rivals that of the Blue-bell; on high mountains where the beauty of the mountain species (*M. alpestris* and *M. dissitiflora*) claims our admiration as much as the Gentians themselves; in the shady shrubberies where the creeping Forget-me-not (*Omphalodes verna*) loves to run wild, and shows its blue eyes in early spring; in the hill copses, where the many kinds of *Symphytum* show their iridescent bells—in all these places we are familiar with their beauty in its many forms. The plants to which we now call attention are, in aspect, as distinct from any of these as it is possible for plants of the same order to be; and yet the individual flower is, in shape and colour, much like those of our garden favourites above-named. The *Echiums* form bushes 2 to 4 feet high, and from these are sent up the most superb spike-like columns of bloom, quite as striking, in their way, as the flower-stems of the Grass Trees of Australia, or of vigorous *Yuccas*, seen in full bloom, with this difference in favour of the *Echiums*—that their spikes are made up of flowers of the finest blue. The spikes are sometimes more than 3 feet long,

each crest-spike being made up of innumerable small ones, on which the flowers open in succession, but in such order that the whole of the column-like spike is for many weeks a mass of blossoms. The species grown here are *Echium arboreum*, *E. fastuosum*, *E. giganteum*, and *E. candicans*, all being blue but the last, which is white. Here they grow quite freely in the open air, and send up flower-spikes freely, too. These are never crowded together, however, but each spike is isolated sufficiently to be seen to good effect. The white kind was in many cases confined to one stem and one great long spike of flowers; whereas the blue species form sturdy bushes. These plants come from the Canary Islands, and well deserve good cultivation with us for conservatory decoration. Indeed, there

are no plants more likely to form a wholly new attraction at our flower shows than these; light, airy, greenhouse treatment would suit them perfectly. Mr. Winter—Mr. Hanbury's able gardener—propagates these fine plants easily by seed sown in April, and also the more branching kinds by cuttings, at will.

Succulent Plants in the Open Air.

As the Gum trees of Australia are quite at home in Southern Europe and in California, so the succulents of the Cape and other hot countries find an equally congenial home here at Mentone. Almost every kind grows well that has been planted out, and the result is a collection of succulent plants of the most extensive and interesting character. Most effective in their way are the nobler kinds of *Agave*—*A. Ixtli*, *A. picta*, *A. ferox*, *A. Cantala*, *A. Rumphii*, *A. laxa*, *A. applanata*, *A. filifera*, and *A. Bouchei*. Other succulents, most conspicuous, are—*Mesembryanthemum edule*, which has yellow and magenta flowers, and many other species; *Opuntia*, many species; *Euphorbia arborescens*, 10 feet high; *Kleinia neriifolia*, large bushes, lately in flower; many other species of *Kleinia*, *Cereus*, *Aloe*, *Haworthia*, *Crassula*, *Cotyledon*, *Rochea*, and *Gasteria*. *Kleinia tomentosa* flowered first in Europe in this garden, and was figured from this specimen in the *Botanical Magazine*. At the end of April, undoubtedly the most beautiful of all these plants are the *Mesembryanthemums*, so much neglected in England. We treat them, where they

are grown at all, as a number of weedy things of "botanical interest." No Gentians, or Roses, or Passion-flowers, possess a more refined and yet brilliant glory of colour than do these, scrambling over the edgings and hanging down the walls to a length of 10 feet or so. By trimming them in and repressing them, we effectually destroy their beauty; by allowing them to hang down freely and gracefully, as is their natural habit, from baskets or pots, we may add many a new and brilliant charm to our greenhouses. And, as scores of the species will thrive in sunny windows, they are, it need scarcely be said, of high importance for the garden in the house. The flowering qualities of some of the *Aloes* make them worthy of a place in our greenhouses, though they rarely get this, and only

Iris susiana as a Border Plant (see p. 477).

appear to attract notice from their foliage; yet the flowers of *Aloe ciliaris* are as showy as a *Tritoma* here, and many other kinds are worthy of culture for their flowers alone. Some of the finer variegated *Agaves*, like *A. picta* (as fine, in its way, as the variegated American *Aloe*), deserve extensive culture with us.

Walls, and how they are Embellished.

We have long advocated the adornment of walls, and enumerated the many plants that thrive perfectly well on them in our cold and wet climate, and here we have an opportunity of seeing how much may be made of walls in a climate where their surface is almost scorched by a blazing sun. In consequence of the ground being terraced here and there, there are a good many walls which have earth behind them, and in such cases a hole made through the wall, and leading to the earth behind, is all that is required for the establishment of some vigorous trailer, which will soon drape the wall with verdure and flowers. The *Mesembryanthemums* would quite suffice for the adornment of every kind of wall here if no other plants existed suited for the same purpose. One kind alone, the crimson form of *M. edule* hangs down the wall for many feet, and bears vividly-coloured flowers, each flower as large as a full-sized *Rose*. The great majority of this fine family will grow in like positions, or between the stones in a rude terrace wall, so that all desiring to adorn walls and like surfaces with plants in warm and temperate regions need not hesitate as to how to begin. The common *Caper* (*Capparis spinosa*) grows here on the walls as it does in many other parts of Southern Europe—and what more attractive than its handsome cups of brush-like stamens? But there is another race of plants from the Cape rarely seen on walls, and which are probably quite as useful for their embellishment as the *Mesembryanthemums*, and these are the various species of *Pelargonium*; both the species and the varieties are at home on walls; but, as many of the fine species are worth a place in our gardens it is, of course, these that have the place of honour; grown in this way and allowed to form bushes, as is their wont, they have a charming effect when in flower. Thus this spreading mass of our old friend, the Citron-scented *Pelargonium* (*P. citriodorum*), which spreads forth at the top of a low terrace-wall and falls some distance down its face, and is in full bloom, reminds us of the specimens of fancy *Pelargoniums* which are seen at our shows. In marked contrast with it is the deep and rich hue of *P. triste*. Here, too, is the original *P. zonale*, parent of a numerous race—itself very much less attractive than many of the species which have never come into general cultivation. All our varieties of bedding, show, and fancy *Pelargoniums* might, in this climate, be grown on walls, if it were so desired. Thus we see that both in warm and cold districts all such surfaces may be turned into interesting and beautiful flower-gardens, and the plants that may be grown upon them are innumerable. What is true of walls in the open air, applies, also, to those under glass, and where they are not designed to bear creepers, it is much better so to form the wall by leaving interstices and hollows in its surface, that plants can root in it with facility. This is, sometimes, now done, as at Baron Rothschild's, at Ferrières. Some adopt the rustic mode of forming the surface of the wall. There is a plan in use here, and, also, in many parts of Italy, even in humble houses, which deserves notice. The low wall which encloses a small terrace, or even a small open landing outside of the windows, is frequently made hollow so as to allow space for a trench of earth from 3 to 4 feet deep and about 2 feet wide; this, filled with good soil, forms a capital border in which to plant anything that may be desired. On the top of a wall so planned a very graceful garland of vegetation may soon be established, while creepers may be allowed to fall freely down the face of the wall.

Plants of Economical and Medicinal Interest.

The garden is remarkable for having a number of plants possessing interest, besides that of their beauty, some of which are not to be seen even in our botanical gardens. They are, for the most part, recently planted, but thriving, and will soon form a feature of much interest to the botanist. Henceforward, doubtless, we must include the Australian Gum trees

among medicinal plants; a little way off—towards Nice, and at the mouth of the Var—some of the commonest species were planted, with the result of making a spot habitable that was previously fatal to human life. There are seventeen species of Gum tree cultivated here; if one species possesses the astonishing properties attributed to it, it is probable the allied kinds have it too; and, on all accounts, the family deserve the attention of cultivators in temperate and warm countries, as the wood is very fine in many cases, the growth rapid, on the part of healthy trees, picturesque, and graceful. A tree of *E. globulus*, planted here in March, 1869, is now 48 feet high. Among the more interesting plants grown are the following: *Catha edulis*, used by the Arabs for chewing; the Chinese Pepper, *Xanthoxylum alatum*, *Z. Bungei*, from Pekin; *Pentzia virgata*, a plant recommended at the Cape for sheep-fodder; *Pistacia vera*; *Myrica sapida*, a new fruit, like an *Arbutus*; the Purple Guava, which ripens its fruit well here in December; the Loquat, which fruits in May; the Edible Passion-flower, which ripens in July; the Kumquat, or small China Orange; the Chinese Quince (*Cydonia sinensis*); *Casimiroa edulis*, yet young; *Diospyros Kaki*, a Chinese fruit, much spoken of lately; the Bergamotte (*Citrus Bergamia*); *Citrus Bigaradia*; the West India Lime; the Pomme d'Adam, the Chinese Pomeloe; and many other plants of like interest, but more commonly met with in botanic gardens; *Argania Sideroxylon*, the Argan tree of Morocco, may also be seen here. It is a spiny evergreen tree, with a trunk of considerable size, but of low stature. It gives off branches at a few feet from the ground, which incline downwards till they rest on the earth; at length, at a considerable distance from the stem, they ascend. A tree mentioned in the *Journal of Botany* for April, 1854, measured 16 feet only in height, while the circumference was as much 220 feet. The fruit is an egg-shaped or roundish drupe, dotted with white. The culture of the plant for the sake of its oil has been recommended in Australia and certain parts of Cape Colony subject to droughts.

Miscellaneous.

Some remarkable specimens of the Shanghai Palm (*Chamærops Fortunei*) are here, with stems from 12 to 18 feet high. These, much higher than we are accustomed to see the plant, are not the products of Mentone, but were imported from China by Mr. Hanbury, coming on the deck of a steamer to Marseilles. Specimens of *Cycas revoluta*, which grew in Mr. Hanbury's garden at Shanghai, accompany these. There are two remarkable specimens of the Date Palm, calculated of the age of 120 and 140 years respectively. A graceful and interesting plant here is *Nandina domestica*, which, in habit, reminds one of some of the herbaceous *Aralias*, but is more slender and graceful; it is one of the most favourite plants of the Chinese, occurring in cottage gardens everywhere about Shanghai; it bears bundles of bright scarlet berries. Another great favourite of the Chinese, *Olea fragrans*, is here also. Of *Acacias*, twenty-five species are grown in the open air, *A. cyanophylla*, *ovata*, *lophantha*, *speciosa*, *nematophylla*, and *brachybotrya*, being the best. Australian plants are well represented, *Banksia marcescens* being in flower. The *Polygalas* we are familiar with in greenhouses in England, thrive here admirably, most noticeable among them being a curious, almost leafless one, called *P. virgata*, a beautiful kind, which, so far as the habit and shoots are concerned, resembles the Spanish Broom; this plant is well worthy of culture in our greenhouses. The single yellow *Banksian Rose* is in its glory here, throwing off long and graceful shoots from walls and trees, up which it is a good plan to let it run. It seems to possess quite as good claims for general cultivation as either of the double kinds; indeed, some would probably think its showers of golden cups, each full of stamens, prettier than the double kinds. These all grow to perfection here, and so luxuriantly that they usually defeat the attempts to train them primly to walls and other surfaces. This is all the better, as the long, slender, and gracefully-curved shoots made during the previous summer are now chains of blossoms. The *Banksian Rose*, with all its flowering branches primly trimmed to a wall, is a very much less attractive object than when these are allowed to spring forth in a free and natural manner. As it is most difficult to grow anything like a verdant or closely-

woven turf here, from the great drought in summer and the scarcity of water, such Grass as there is is dotted full of Anemones of various sorts, and other wild flowers of the district; and thus, instead of a lawn, we have a pretty wild flower-garden. Many scraggy occasionally-mown spots in the rougher parts of English pleasure-grounds would look all the better for being treated in a somewhat like manner. A *Bougainvillea* of extraordinary richness of colour (*B. Warszewiczii*) was, though a young and small plant, full of flower; its merits are probably not yet known to English growers of these plants.

W. R.

THE INDOOR GARDEN.

VARIEGATED ORCHIDS.

WHILE by far the greater number of cultivated Orchids are grown solely for the sake of their beautifully coloured, singularly varied, and often fragrant flowers, and present nothing remarkable in their foliage, there are two genera of terrestrial kinds (*Anætochilus* and *Physurus*) the leaves of which are richly coloured and highly ornamental, while the flowers are quite insignificant. The two genera are very closely related to each other, although they belong to widely distant regions, the *Anætochili* being indigenous to the East Indian Islands and Continent; while the *Physuri* are natives of tropical parts of South America, and especially of Brazil. All the species of both have short rhizomes, very short stems, and alternate leaves, more or less oval in shape, often heart-shaped at the base and pointed at the apex, on very short foot-stalks, which embrace or clasp the stem. The flowers are arranged in clusters or terminal spikes. They are of a white or reddish colour, and are undeserving of notice, in an ornamental point of view. The difference between the two genera consists chiefly in the colouring of their leaves and the distribution of their habitats. The leaves of the *Anætochili* are generally more velvety, and their veinings are mostly of a golden-red colour—rarely white. The leaves of the *Physuri*, on the other hand, are distinguished by their brilliant green colour and their silvery veinings. The native countries of each have been already mentioned. *Anætochilus Lobbianus* (of which we give an illustration) is one of the finest of the genus. It is a native of Java, and was named after Mr. Thomas Lobb, who introduced it into Europe. Its leaves are oval, pointed at the apex, velvety, of a very dark green colour round the margins, while the central part is of a yellowish-red. The whole of the upper surface is traversed by a net-work of veinings of a brilliant golden-yellow colour. The under surface is red. The plant is also known in gardens under the names of *A. xanthophyllus* and *A. latimaculatus*. Of other *Anætochili* a descriptive account of the most ornamental species will be found at p. 180 of our current volume. Of the genus *Physurus*, these are the finest species in cultivation:—*Physurus pictus* (Lindley)—also known as *Anætochilus pictus argenteus* (Hort.) *Physurus pictus reticulatus* (Reich. fil.)—and *Microchilus pictus* (C. Morren). This is a native of Brazil, and is distinguished by its lance-shaped, brilliant green leaves, with silvery veinings. *Physurus argenteus* (Hort.) (*P. pictus holargyrus*—Reich. fil.), is a kind which is sometimes confounded with *pictus*, from which, however, it is distinguished by the oval-

Anætochilus (xanthophyllus) Lobbianus (natural size).

pointed shape of its leaves, which are also heart-shaped at the base. They are of a deep green colour, marked with fine large silvery veins, and a net-work of numerous small secondary veinings of the same colour. All these plants require the same treatment, that is, they should be grown in pots, the lower half of which should, for the sake of securing perfect drainage, be filled with broken crocks, while the rest of the pots should be filled with a compost of peat, charcoal, and Sphagnum, the surface being covered with a layer of living Sphagnum. The plants, after being potted, should be placed under a bell-glass or cloche, in a warm house, where the temperature during summer should range from 70° to 78° Fahr., and in winter from 55° to 60° Fahr. A moist atmosphere is indispensable, and this should be maintained equally and constantly during the summer, but in winter, when the plants require some rest, the supply of moisture should be considerably diminished. The plants should at all times be kept well sheltered from the direct rays of the sun, and the inside of the bell-glass or cloche, under which they are placed, should be carefully wiped out every morning and evening, otherwise the condensed moisture, accumulating on the glass, will drip on to the leaves, making

holes wherever it touches. As the principal object in cultivating these plants is to bring the foliage to its full perfection of beauty, the flowers should be pinched off as soon as they begin to appear. This will throw more vigour into the leaves, cause them to grow closer together, and vastly improve the lustre and richness of the colouring. It is also favourable to the multiplication of the plant, as it causes numerous shoots to spring from the axils of the lower leaves, and also from the rhizome. These shoots, when detached and planted, will form each a new plant. They should, of course, be potted in the same compost, and subjected to the same treatment which has been above described for full-grown plants. Of variegated Orchids in general, the following is a list of some of the more remarkable, viz., *Anætochilus argyroneurus*, *A. Bullenii*, *A. Dayii*, *A. Dominii*, *A. El Dorado*, *A. intermedius*, *A. javanicus*, *A. latimaculatus*, *A. Lobbii*, *A. Lowii*, *A. L. virescens*, *A. Nevilleanus*, *A. petola*, *A. querceticolus*, *A. Reinwardtii*, *A. Ruckerii*, *A. setaceus*, *A. s. cor-*

datus, *A. s. grandifolius*, *A. s. inornatus*, *A. striatus*, *A. Turnerii*, *A. Veitchii*, *A. xanthophyllus*, *A. zebrinus*, *Cypripedium barbatum* (several varieties), *C. concolor*, *C. Dayii*, *C. Harrisianum*, *C. Hookeræ*, *C. niveum*, *C. pardinum*, *C. purpuratum*, *C. superbiens*, *C. venustum*, *Dendrobium japonicum variegatum*, *D. nobile variegatum*, *Goodyera Dawsoniana*, *G. discolor*, *G. Dominii*, *G. macrantha*, *G. Ordiana*, *G. picta*, *G. pubescens*, *G. rubro-venia*, *G. Veitchii*, *G. velutina*, *Microstylis discolor*, *Oncidium Papilio*, *Orchis maculata superba* (many other species), *Ophrys* (many species), *Phajus maculatus*, *Phalænopsis Schilleriana*, *Physurus argenteus*, *P. a. pictus*, *P. fimbrialis*, *P. maculatus*, *P. nobilis*.

W. M.

TYERMAN'S HARE'S-FOOT FERN.

(DAVALLIA TYERMANII.)

NEARLY all the Hare's-foot Ferns are beautiful, being elegant in habit, and they are also well adapted for cutting and for grouping either in bouquets, vases, or as dinner-table decorations. This, which is one of the most distinct species in the whole group, has been named, in compliment to the

late curator of the Liverpool Botanic Gardens, Mr. Tyerman. It is easily distinguished from its congeners by its silvery rhizomes and dark glossy fronds, which are of good substance, and, like those of many other species of the genus, last for a considerable time after being cut. It grows well in the ordinary temperature of the tropical Fernery or plant-stove, in an open and well-drained compost of peat, fibrous loam, and coarse sand. It does better in a basket or flat earthenware pan than in a pot, as its rhizomes have in that case liberty to develop themselves fully, and they are also seen to much better advantage than when crowded together. It likes to creep among lumps of rough peat and nodules of moist sandstone. It has been imported from West tropical Africa, and ought to be grown in every select collection of stove Ferns.

B.

LARGE SCARLET-FRUITED SOLANUM.

(SOLANUM BETACEUM.)

AMONG easily-grown ornamental plants of large size which are employed for forming groups, *Solanum betaceum* is particularly valuable. It is a native of Brazil, and forms a handsome bushy shrub 16 feet or more in height, and as much in circumference. The leaves are of a deep green and the flowers of a pale blue. In September the plant is covered with a multitude of scarlet fruit, as large as a hen's egg, and presents, all through the winter, a magnificent appearance in well-grown specimens. It requires the heat of a temperate house to ripen the fruit. The plant is easily raised from seed, which should be sown in pans on a hot-bed, and, as they germinate very rapidly, the seedlings may be potted off in about eight days, and removed into the open air for the summer about the beginning of May. The fine foliage and blue flowers of the plants will add much to the attractions of gardens during the season. At the approach of winter, and before the appearance of frost, the plants should be re-potted in pots of suitable sizes, and removed into the plant-house. The soil used should consist of two-thirds peat soil and one-third free loam. During the winter water should be very sparingly given. Some idea of the beauty of this plant may be entertained from the account of a specimen given by M. Telli re, in the *Revue Horticole*. This, he states, was over 16 feet high, and bore 1,200 fruits of a brilliant scarlet colour, and each as large as a hen's egg. The *Solanum betaceum* appears to be hardly known in this country, but it is well worthy of cultivation, either for summer or winter ornamental purposes. Seed of it is not expensive, and may be obtained, we believe, from M. Loise-Chauvi re, nurseryman, 14, Quai de la M gisserie, Paris.

W. M.

Green-leaved Drac nas.—It may not be sufficiently well known that this section of ornamental Dragon trees is much hardier than the crimson or creamy variegated kinds. This is a fact, however, and it ought to make the green varieties very popular as decorative plants for rooms, windows, and other situations in the house. The best species are *D. congesta*, *D. rubra*, *D. gracilis*, *D. heliconiaefolia*, *D. Draco*, and *D. latifolia*, all of which have fresh green foliage more or less elegantly recurved, and are invaluable either to the amateur or professional floral decorator. I have often thought that if seedlings were raised from home-saved seeds a still hardier race of *Drac nas* might be obtained. *Apropos* of this, I may mention that a plant of *D. latifolia* now bears a great panicle of large greenish-white flowers, in the succulent-house at Kew, and it is by no means unusual for many of the other species to bloom in this country; and, with a little care in fertilisation, some interesting and useful hybrids might possibly be obtained.—B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Agapanthus umbellatus as a Balcony Plant.—I have two large plants of this that have been established in small tubs for years, and each of them is this season throwing up about a dozen spikes of bloom. They succeed perfectly in any good turfy compost, but require a liberal supply of water at the root, especially during hot dry weather.—J. H., *Sydenham*.

Boronia megastigma.—This is the reverse of attractive, so far as bright colours are concerned; but its blooms are very fragrant. I selected a plant of it some months ago from a list of new plants, but when it first opened its flowers I was disappointed with it. It is one of those plants that do not captivate at first sight, but its graceful habit of growth and delicate perfume make it a favourite.—B.

Sobralia macrantha nana.—Of all the varieties of *S. macrantha* we have ever seen, this, received direct from our Mexican collector, is by far the finest. It flowers profusely when only 12 to 20 inches high (one of our flowering stems is only 11 inches high), and the labellum alone of the plant now in bloom with us is 10 inches in circumference, altogether it is one of the most charming Orchids imaginable. Every plant of it that we have is the same, the tallest stem being only 23 inches, and this a solitary exception out of 15 or 20 stems.—JAS. BACKHOUSE, *York*.

THE GARDEN IN THE HOUSE.

BOUQUETS FROM FIELD AND GARDEN.

IN reviewing the flower-painting of this year's exhibition of the Royal Academy, it was observed by THE GARDEN in the notice of Miss Mutrie's "My First Bouquet," that the fashionable "cauliflower" bouquets of the present day might be occasionally supplemented by a freer style of grouping, in which the foliage of each flower should play a part, however subordinate. The excessive formality of the present orthodox form of presentation or ball-room bouquets, exhibits a kind of close packing in which the delicate graces of flower-form are entirely submerged in consequence of this close, even tight, juxtaposition. The end sought in this kind of grouping, appears to be a method of packing together (according to price) an abundance of rare, and, consequently, expensive flowers, all of which must be got into the same lump. This system, of course, necessitates the use of such flowers as are more or less rare, and there is, perhaps, no other way of making up a bouquet that shall be fairly worth, in intrinsic value, from 5s. to 5 guineas. The cut flowers of which the bouquet is composed are, probably, worth all the money, at their respective market prices; and, for certain occasions, bouquets so manufactured, may be deemed appropriate, even necessary; but as works of art they are utterly valueless. A few elegant Grasses from the meadow, combined with a selection, at any season, of flowering branchlets from the shrubbery or common garden border, and a free-handed and tasteful grouping, without crowding, and with a well-balanced proportion of natural foliage, may be made to form a composition, such as a painter might desire to transfer to his canvas, while he assuredly could never wish to dip brush in colour for one of the expensive bouquets of the "cauliflower" type. Such has long been a favourite theory of the writer in the matter of flower grouping; and the other day he found it gracefully exemplified on the drawing-room table of a friend, by a graceful half-wild bouquet from field and garden, formed with the free grace and uncrowded arrangement which, as nearly as may be, illustrated his views. It is needless to state that a lady's fingers and a lady's taste were the joint authors of the composition. In the arrangement, each flower and Grass of the gathering had been made to find its seemingly proper place, unjostled by its neighbour, and so freely and easily located in its basket-work receptacle, supported on three slender canes of Bamboo, that even its foliage had room to display its graces and modes of growth. With the permission of the lady flower-grouper herself, a drawing was at once made for this journal, a reproduction of which, in the form of a careful wood-engraving will be found on the opposite page. The central object was a small spray of Guelder Rose, with two or three of its spherical masses of snowy flowers, surrounded and supported by their own leaves. There was also a Rose, perhaps one of the first of the season in the garden where it was gathered; and there were some smaller Scotch Roses, accompanied by sprays of their miniature foliage. There was also, it will be seen, a flower of white Pink, with buds, and with leaves which have room to display their delicately slender forms and the pale glaucous hue of their dainty green. A common Corn-flag towered in the centre; and on the left was a single Iris, backed by its blade-like leaves. Grasses of several kinds shot upward, crowned by their feather-like inflorescence, which added a pleasing lightness and careless grace to the composition. The effect was heightened as regards colour by two sprays, not more, of *Pelargonium* flowers, gathered with their leaves; and additional grace was secured both by drooping Grasses, and by two or three kinds of Fern, one gracefully-weeping frond being allowed to droop negligently to the table, the slender extremity of which curled itself fantastically, as with a set declaration against primness, trimness, or any kind of slavish formality. The value of our native Grasses for arrangements of this kind is well shown in this case. Ferns themselves cannot show so airy a grace or such delicacy of form. Many graceful wild Grasses may be gathered in our hedgerows, and many beautiful hardy Grasses, not natives of this country, are as easily grown in any cottage garden as the hardy flowers of which this charming bouquet was composed.

H. N. H.

THE KITCHEN GARDEN.

FERTILISERS AND THEIR PROPERTIES.

By THOMAS BAINES.

SCIENCE has done much during the present century for horticulture in the way of manures; yet, even amongst the most learned in such matters considerable difference of opinion has existed; what one has pronounced to be an established fact, another has pulled to pieces, as a conclusion based upon mistaken observations and insufficient data; this applies more especially to combinations or mixtures of manure; for instance, by one we are told that the man who allows lime to be mixed with farm-yard manure simply wastes both, and throws his labour away into the bargain; then, by another, we are informed that this is a mistake, that the combination answers admirably—sound alike in theory and practice. In the use of manures quite as much depends upon the nature of the soil as upon the particular crop for which we are manuring; and this difference of soil exists in almost every locality; nay, further, it frequently happens that two pieces of land, only separated by a fence, are so different in this respect that the particular manure adapted for a given crop upon one may be anything but the most suitable to use for the other under a similar crop. Let me not be misunderstood; I should be extremely sorry to in any way disparage the importance and benefits conferred upon horticulture by means of chemical research, when confirmed by actual experience, but without this all-important confirmation, I look upon practice handed down from generation to generation as a safer guide to follow than the chemist in his laboratory, who is unacquainted with the nature of the soil for which he prescribes a particular manure. Plants, in relation to the food that sustains them, stand in a somewhat analogous position to animals; what is food for one is poison for another, with this important difference, that if distasteful the animal will refuse it; not so the plant, which has not the power of rejecting, however unsuited or inimical may be whatever is contained in the soil in which its roots are placed. This is a fact well known to anyone who has observed the beneficial effects of dressings of salt upon marine plants, such as Asparagus and Seakale, heavy enough to have caused death if applied to others different in their nature. In the numerous subjects the gardener cultivates, the opportunity exists for combining science with practice, through the exercise of careful observation, but, it is not always that this very necessary element is brought to bear; often, there is the same yearly application of identically the same kind of manure, for all, and every variety of crop that has been used for time immemorial. There are innumerable gardens where stable-manure, leaf-mould, and other vegetable matter has been used until the whole body of soil has become a mass of humus incapable of growing many things. Vastly preferable to stable manure for general use in the garden, is such as is obtained from the farm-yard, viz., a mixture of that of horses, cows, and pigs, all carried away together as it is made; not only does this contain from the first the elements necessary to maintain the soil much longer in a fertile state, but there is so much less waste in the process of fermentation, consequent upon the mixture never heating to a degree that will expel the ammonia. Yet even the mixture of manure just named admits of being much improved by the regular addition in the preparation of an absorbent, such as ordinary loam, peat, charred garden refuse, or burnt clay; if any of these are used in the proportion of one-half, or one-third, a given quantity of this manure, so prepared, will do at least one-third more good than the usually half-exhausted stuff applied to most gardens. In many places there does not exist the means or convenience for obtaining the manure fresh as it is made, or for preparing it in the above manner; but there is no reason why such provision might not be made. By the use of such, we should hear much less seldom of gardens being worn out. Again, the quality of manure is considerably improved by the position in which it is placed whilst being prepared. The old method was to throw it into a hole, which, being a downhill movement, was, of course, the easiest to begin with; but there was the after difficulty of getting it out again, without taking into account the waste occasioned by

the accumulation of surface-water in such places, in brewing the strength out of it. A manure heap should always be on, or above, the surface level, and so placed that there can be no accumulation of water, and where the little that does run from it can be collected in a tank made for the purpose. Liquid-manure is required for most things, and this will be found to be sufficient, and much less labour, than the especial preparation of horse droppings. In the preparation of manure, as collected together, it is impossible to make it too solid. Excessive fermentation never will take place, unless it contains too much air, which cannot occur if the whole mass lays perfectly close. The extra strength of manure, made and allowed to accumulate in cattle boxes, where the animals run loose, treading it down as closely as possible, is due more to its losing nothing by fermentation through the solidity which the whole mass attains, than by its protection from rain. The Cheshire farmers in the neighbourhood of Manchester know this, and profit by it. When in the autumn they have selected the ground for their next year's Mangolds, Turnips, and Potatoes, they commence drawing large quantities of manure, principally from Manchester, placing it upon the highest point of land on which they intend to use it, and, instead of laying it loose and high, they make the heap a low oblong square, sloping down to nothing at both ends, so that they can draw each load with the horses as it comes right on to the top. The feet of the horses and the wheels of the carts make the whole mass so close that it never heats, so as to injure it. To every two loads of stable manure, of which this principally consists, one load of fine ashes from the dust yard is added. This acts as an absorbent; and manure so treated loses little in bulk from the time it is put together until it is carted on to the land, and will cut out almost as solid as clay. This, in itself, is sufficient proof, without any chemical test that the manure loses little of its natural strength, a fact still further confirmed by the enormous crops obtained by moderate dressings. To secure the best results in the cultivation of any particular plant, it is not only necessary to select such manures as, by their natural constituents, are best suited to the requirements of the species of plant we wish to grow, but also such as are rich in the particular element in which the soil happens to be deficient; this latter can only be determined by analysis of the soil, or by its apparent nature confirmed through actual experience; consequently, this only admits of being treated from a general point of view. For most descriptions of soil and of crop, good farm-yard dung stands unequalled; but, as I have already attempted to show, it may be applied to a particular piece of ground until it produces not nearly the effect it ought to. Highly concentrated ammonial manures, of which we may take good Peruvian guano as the type, are much more suitable for crops, such as Turnips, Beet, Carrots, Parsnips, Cabbages, Lettuces, or anything of a similar character (wherein the object is to build up the substance of the plant quickly without the introduction of any more fibre into it than can be avoided) than they are suited for such things as Peas, Beans, French Beans, or anything of which the seed is the edible part; nevertheless, they are all excellent substitutes in part for solid manure, where such happens to be deficient. Where the soil has become almost effete, and reduced to humus, causing the crops to run too much to haulm and leaf, liberal dressings (not mere sprinklings) of lime will be found advantageous, with an alternate application of common salt, more especially if the land is very dry, the nature of the salt helping to retain moisture. The most enduring of animal substances, bone, horn, hoof-parings, hair, and woollen rags, are amongst the best and most lasting manures, and are not near so much used in gardens as they ought to be; all these, except bones, may, with advantage, be applied to any description of soil. Bones do not answer well on very dry light land; for, unless they are dissolved, their decomposition on such soils is too slow.

What are the Advantages of Double Cropping?—About this season gardeners in many places are in the habit of double cropping, which, in my opinion, is a bad practice. I should be glad to learn what are its advantages. Shade might, perhaps, be afforded between rows of Peas or Beans, but then the benefits derived from

summer showers, which are needful, would be, in a great measure, denied. Then there is a great interruption to the ordinary operations. In removing Pea sticks, for instance, even with the greatest care, injury will occur to the other crop, which is always inferior to one not so confined; then the soil has to be loosened up again, making three loosenings in the season. All this is too much where sufficient strength to work the garden is not allowed. Double cropping might be admissible in cottagers' gardens, where space is limited; but, when a gardener has four or five acres of land to attend to, with only some three men to do the work, to double crop part of the kitchen garden is too much. What think your readers?—A SUBSCRIBER.

MULCHING IN THE FRUIT, FLOWER, AND KITCHEN GARDEN.

At this season of the year, mulching (*i.e.*, covering the surface of the ground between growing crops with some loose material to prevent evaporation) effectually will save much labour in watering, and to a very considerable extent make up for poverty in the soil. Materials for mulching are generally plentiful in most gardens; decayed hot-bed manure is one of the best, and when this cannot be had, short Grass is generally plentiful. Most fruit and vegetable crops are benefited by mulching, but some more so than others. The Raspberry, for instance, which delights in a somewhat moist soil, and is a shallow rooter, should always be mulched in dry situations. Our soil is dry and thin, and not well adapted to the Raspberry; but by mulching thickly, we always secure great crops of fine fruit. In fact, the weight of the fruit is nearly doubled in consequence. Celery, too, is mulched thickly with short Grass as soon as planted, and it seldom requires more than one or two good waterings. Let the weather be ever so dry, the surface under the Grass is always moist. The mildew which affects the Pea in dry summers, is greatly checked, or altogether prevented, by good mulchings along the rows, and extending outwards from the sides about 18 inches. Brussels Sprouts, Broccoli, Cauliflower, &c., which often hang fire after planting in a dry June, make marvellous progress with their roots under a good layer of short Grass. Potatoes, though they, too, are much benefited by the same means in dry seasons, are better without it, as a rule, in case of wet setting in in autumn, and thereby aggravating the disease; but this is the only exception. The health of Gooseberry and Currant bushes is greatly promoted by mulching, and indeed all kinds of fruit-trees, especially stone-fruits; and newly-planted trees of all descriptions are often saved from perishing by a good top-dressing of rotten litter, and such like, during summer and winter. In the flower-garden, mulching is not so admissible, but we generally practise it with Calceolarias, and the disease is unknown with us, though we have to contend with a dry caky soil. The Iresine, too, should be mulched; it is a moisture-loving plant, and will thrive if mulched where it will sometimes not do any good otherwise. In Vine and Peach borders, whether inside or outside, mulching is almost indispensable. In some places where they are raked painfully smooth and neat, sometimes they get so rent with the drought during summer, that a man has to go over them every week to fill up the cracks. Good Grapes are seldom to be found under such circumstances. A mulching, 4 or 5 inches thick, of rotten litter and leaves is best for Vines, and a border so dressed need never offend an eye not painfully sensitive on the score of neatness. Large plants in pots, such as Figs, pot Vines, Pines, orchard-house trees, &c., should also be mulched when practicable, as roots are often near the surface, and are apt to suffer from irregular attention in watering. Apart from the advantages of mulching in a labour-saving respect, and as a conservator of moisture, it keeps the soil about the roots at an equable temperature, by preventing radiation in cold weather, and the bare soil from the roasting effects of the sun in warm weather—a condition of things very unfavourable to vegetable life generally.—*Gardener.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Early Peas.—Our first Peas were Ringleaders, which were gathered here on the 21st ult., and Laxton's William the First came in on the 26th. The latter is a green Marrow of the first quality, and a decided acquisition.—R. G., *Burghley.*

Large Rhubarb.—Is this anything extraordinary in the way of Rhubarb: the stem (cut off close to the ribs of the leaf), 20 in. long, and 9 in. in circumference; weight 3 lbs. 13 oz. ? If so, I have just cut a stem agreeing to this description.—JOHN MARTEN, *Chilham, Canterbury.*

Potatoes and the Late Frosts.—The frost caught us napping the other day; but we, nevertheless, learn something even by disappointment. American Potatoes are not of the best quality, far from it, but that is not their only fault. I grow Climax because it grows large and early; also, Early Rose, but it is most tender, all of it here having suffered, while the good old Lapstone Kidney is not touched, and is the prince of Potatoes, when of the true kind.—R. GILBERT, *Burghley.*

GARDEN DESTROYERS.

SCARING BIRDS.

YOUR correspondent, "R. C. E." (p. 465), in his remarks on scaring birds off fruit-trees by means of squibs and crackers, has, I fear, not given us gardeners an effectual remedy to get rid of our feathered enemies. We have all heard of catching birds by putting salt on their tails, and I am surprised that "R. C. E." has not alluded to this plan. The four-and-twenty young birds and thrushes baked in a pie along with pigeons is, however, not a bad idea; and half-a-dozen pies of such dimensions, in the course of the season, would help to thin the young generation of these birds. These pies, however, would not be supplied with young birds, caught by means of twigs loaded with bird-lime, or with springes or nooses of hair or wire; on the contrary, the gun, traps, or nets would have to be resorted to in cases of necessity. I am not sure that young blackbirds and thrushes do all the mischief in our fruit-gardens; for the old ones, whether moulting or not, I have found quite as bad and more daring. I believe the thrush is entitled to more lenity than the blackbird in the fruit season, for it is not nearly so daring or ravenous as a fruit eater, and it destroys incalculable numbers of slugs and grubs in spring and autumn. "R. C. E." alludes to a tender-hearted gamekeeper who was horrified at the barbarity of catching rabbits with steel traps; he must, I should think, have been the very first of his profession to show such qualms of pity. Such a man, of course, would never think of catching hawks, weasels, cats, or birds of any kind by such means; and he must have been a valuable servant on account of the heads of game which he reared for his employer. If squibs and crackers, and pieces of touch-paper, and similar petty fireworks, will help to scare away blackbirds and thrushes in the fruit season, the time will soon arrive for the trials to commence; and those who put their trust in "R. C. E.'s" recommendations must keep their powder dry for the occasion. W. TILLERY.

Receipt for destroying Thrips.—Dissolve 8 lbs. of the best soft-soap in 12 gallons of warm rain water; then, when the water is cold add a gallon of strong tobacco juice. Indian Azaleas are very subject to this pest, and if the plants can be dipped in this mixture, or, if too large, syringed with it twice, at the interval of two or three weeks, it will quite clear them of it. After dipping or syringing the plants with this mixture, and before it dries on the foliage, it is safest to syringe them again with clean soft water; thus all the dead insects will be washed off and the foliage made clean. Fumigation with tobacco is a good check against the thrips, if repeated at intervals of three or four days, but nothing is so effectual as dipping in the above mixture.—T.

Poke-root for Destroying Insects.—Dr. F. C. Renner, of Frederick County, Maryland, writes to the Department of Agriculture at Washington, that several years ago he collected some Poke-root (*Phytolacca decandra*) for medicinal purposes, and placed it at various places about the house to dry. After several days he observed that there were many cockroaches lying dead, and upon examination found they had been partaking freely of the Poke-root. Some of the root was placed near their haunts, and the result was that it rid the premises of those insects. Since then he has communicated the remedy to others, who have tested it with satisfactory results. We have not yet had an opportunity of trying the efficacy of the root as an insecticide, but shall test it in the spring. Should any of our correspondents have experimented with it, they will oblige us by giving the result of their experience before we venture to recommend it for general use.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Rhubarb Leaves a Cure for Crickets.—A large bakehouse at Turvey, Beds., was, some years ago, infested with crickets. As hot weather came on the nuisance became very serious, for crickets were to be found in every possible crevice. The baker was advised to lay some Rhubarb leaves about the place. The light of the next morning revealed nibbled leaves and myriads of dead crickets; and this was the last of them in that bakehouse.—E. RANSOM.

Fern Insects.—What is the name of the pest which has affected the Fern, a piece of a frond of which I enclose? I cut it off a Stag's-horn in the conservatory of a friend. The frond is smothered, as you will see, with the insect, and is the only plant so affected; small black ants also seem to take great interest in such plants, for the Fern in question is covered by them all day?—G. E. P. [Your Fern frond is covered with the tortoise scale also called black turtle scale (*Coccus testudo* of Curtis). The best modes of getting rid of it are described in the recent papers in THE GARDEN by Mr. Baines (see p. 90, Vol. V.).—A. M.]

THE ARBORETUM.

ROSA INTERMEDIA.

THIS very singular species (or variety) was raised by M. André Leroy, nurseryman, of Angers, from seed which he received from China, and, if not particularly remarkable for beauty, it has, at least, the merit of being quite unlike any other known species or variety of the Rose. At first sight, when in flower, it might be easily taken for a Rubus, or Bramble, of the Fruticosus section. It is a very vigorous-growing climbing shrub, with cylindrical branches, covered with smooth shining bark, leaves very coarsely toothed, and exceedingly numerous, fragrant, pure white flowers with yellow anthers, borne in a large cluster of terminal cymes, as shown in the illustration. This plant, though not devoid of interest as an ornamental subject, claims attention in a scientific point of view. The specific name (*intermedia*), is most appropriate, as, from its organic characteristics, it undoubtedly belongs to the genus *Rosa*, while, from its general aspect, and especially in the disposition of its inflorescence, a superficial observer might be inclined to refer it to the genus *Rubus*. The habit of the plant is shown in the accompanying illustration.

SKIMMIAS.

THE genus *Skimmia* was founded by Thunberg on a single species (*S. japonica*), which, for a long time, was the only one known in cultivation. Now, however, we are acquainted with at least five species, which we shall proceed to describe, beginning with

***Skimmia japonica*.**—This plant is very ornamental on account of its berries, which remain on the shrub a year or more, rendering it one of the handsomest subjects for winter decoration. In general appearance and in its fruit, it resembles *Ardisia crenata*, with which, however, it has no family relationship. It is a dwarf Japanese shrub, with small, persistent, leathery leaves, narrowed to a point almost from the base; flowers, hermaphrodite, arranged in spike-shaped terminal clusters, with four (rarely five) petals, white or slightly greenish, and with a very agreeable perfume, resembling that of Orange-blossoms; stamens, four (five in the flowers with five petals); filaments, white and thin, inserted in the middle of the yellow anthers; ovary, small, surmounted by a thickly three-lobed style; fruit, the size of small Peas, of a very brilliant coral-red colour when ripe, and continuing for a very long time before they fall. Flowers in April and May. As the fruit continues persistent for such a long time, it frequently happens that plants may be seen bearing flowers and fruit together.

***S. oblata*.**—This species appears to be intermediate between the two preceding ones. It is also from Japan, and is equally hardy. The female plant has persistent leathery leaves, slightly arched, on short stalks, sometimes nearly sessile, frequently of two forms—the one from 3 to 5 inches long and about 2 inches broad, the other oval, broader, and much shorter, of a very deep green, almost black, colour; flowers, fragrant, terminal, in a short thyrsoid cluster, with four (rarely five) spreading distant petals, which are red on the outside before expanding, and white afterwards; stamens, rudimentary, being reduced to small white filaments; ovary, large, surmounted by a stout broadly four-lobed stigma.

***S. fragrans*.**—This plant is also from Japan, and is very hardy.

Rosa intermedia.

It exhibits this peculiarity, that although the flowers begin to show before winter, they do not, however, begin to expand until the following spring. The flower-buds, however, do not suffer in the least from the winter's cold. The male plant is a very hardy vigorous-growing shrub; leaves, persistent, thick, leathery, slightly arched, sometimes slightly twisted, from 5 to 6 inches long and nearly 2 inches broad, of a deep shining green colour. Inflorescence, terminal, in a broadly thyrsoid cluster, 5 inches or more in length, and 3 to 4 inches in diameter, broadly rounded at the apex, and with numerous dichotomous ramifications; flowers, fragrant, white or faintly yellowish, with four (rarely five) oboval nearly erect petals; stamens, equal in number to the petals, with white filaments supporting large yellow anthers; ovary, rudimentary.

***S. Veitchii* (Nob.), *S. oblata* (Hort.)**—This species, which is the finest of the genus, in its habit, and especially in its foliage, is also from Japan, and, like the preceding, is very hardy, bearing our winters without injury. It is a dioecious shrub. The female (which alone we have seen) is very vigorous-growing, with oval or oboval-elliptical, very thick, leathery leaves, not arched, abruptly rounded at the apex, of a light green or slightly yellowish colour, with very thick violet-red leaf-stalks, and with a yellowish mid-rib, from 3 to 5 inches long (sometimes more) and over 2 inches broad; flowers in a terminal spiked-shaped cluster, with four (rarely five) oval petals, which soon fall, and with the odour of *S. fragrans*, but not so strong; stamens, reduced to white filaments; ovary, large, surmounted by a four-lobed stigma, the lobes of which are less spreading than in the preceding species.

***S. Laureola*.**—A dioecious shrub, with very fragrant yellow flowers. As distinguished from all the other species which we have studied, in this the sepals, petals, and stamens are five in number in each flower. It is a handsome ornamental shrub, with persistent leaves, and in winter requires the shelter of a conservatory, where it flowers about the end of March. The following is the description of this species given by Siebold and Zuccarini:—"An elegant shrub, about 4 feet high, exhaling a citron-like odour; flowers of a pale yellow, very fragrant, in a dense terminal corymb; berry, oval, smooth, very large. Native of the mountains of Nepal."

As may be seen from the preceding descriptions, all the *Skimmias* are from Japan, and are very hardy, with the exception of *S. Laureola*, which is a native of Nepal, and cannot withstand frost. These plants, when they become more common, will

render important services to horticulture. Although they accommodate themselves to various kinds of soil of a sandy-clay nature, it is best to grow them in heath-soil when they are young. They are very easily propagated, as few plants are more readily raised from cuttings. All that is required is to take cuttings of well-ripened wood, and place them under cloches, where they will strike root in a very short time. The species which fruit may also be multiplied by means of seeds. According to Siebold and Zuccarini, the Japanese and Chinese class the *Skimmias* amongst poisonous plants, the native name, *Sikimi*, signifying an "evil fruit."—*Revue Horticole*.

HEDGES FOR EXPOSED SITUATIONS.

THERE are few plants suited to withstand the rigour of severe winters sufficiently to form fences in high situations; and those which are adapted for this purpose are to be considered chiefly as the forerunners of the Beech and Whitethorn. There are, indeed, certain situations, though few, where it would be an act of folly to be at the expense of planting any fences with the view of sheltering, and ultimately reclaiming, the land for cultivation. Rocky surfaces,

such as cannot be subjected to the plough, belong simply to the province of the planter. Thin gravelly districts, where herbage refuses to take root, are also to be left to be covered with ligneous vegetation, as are all those lands lying on rock, or which otherwise have such a retentive sub-soil that the water stagnates upon them. At the same time, the mere altitude of lands ought to form no barrier to the introduction of hedge-plants, so long as we have a few prepared to take their station in the shape of fences in any situation; the chief thing to be considered being, whether or not the soil purposed to be enclosed is likely to become fit for tillage.

The Scotch Pine.—Of all the trees suited to the climate of Britain, this tree is, perhaps, the most serviceable. If the cold and wintry uplands of the north are to be brought into cultivation, it will be by the aid of this tree, either in hedges or strips, or in larger masses as nurseries to other trees. In no soil does it refuse to grow. In peat, sand, gravel, granite, and all thin soils, it rises rapidly, and forms a strong rough fence in the course of six or seven years. In the neighbourhood of Thetford and Newmarket, in Suffolk, where the soil is miserable, it is quite common as a hedge tree; but in those places it is pruned in the same way as the Whitethorn, which is certainly disadvantageous; it being well known that of all trees the Pine is the most impatient of the knife. It is only where a better tree, as a fence, will not grow, that I am led to recommend the Scotch Pine, and this I do, as already stated, because it is admirably adapted for ameliorating the climate in exposed situations previous to the introduction of others. My plan with this tree is as follows:—The soil requires no preparation whatever. The plants to be used should be four years old, and they can be had of nurserymen for 4s. or 5s. per 1,000. Those plants I insert in a straight line at 2 feet apart from each other, so that, when they get up, the stems may form the chief part of the fence. Planted at this distance, there will be very little room for branches between the trees in the lines, but they will push out luxuriously on each side and produce sufficient spray to keep the plants in a healthy state. The tips of the strongest side-branches should be cut off, so as to induce smaller ones to break forth, but no regular system of pruning should be adopted. Another parallel line is to be formed and planted in like manner, about 6 yards distant from the other: this distance I adopt, so that the roots of the trees may not impoverish or reach the soil in the centre, which, at the proper season, should be planted with the Whitethorn or Beech after the ground is trenched in the usual way. Between the parallel lines, at considerable distances, there should be cross lines planted so as to break any currents of wind, which are oftentimes hurtful in open avenues of this description. If the soil is tolerable, and the climate permit, the Whitethorn-hedge may be introduced three years after the planting of the Pines; but in the more exposed places, it should be deferred for a year or two longer, when the screen on either side will be in a more complete state to protect it. At the end of the three years, the Beech may with every prospect of success be introduced.

The Furze.—In very cold elevated districts, where others will not thrive, this shrub makes a beautiful and useful fence—beautiful from its having such a profusion of bloom, and useful because it is cropped in winter by sheep, and the clippings eaten by cattle and horses. It is short-lived, however, and is subject to be killed down during severe winters. It is apt, also, to become bare and unsightly at bottom. In forming a hedge of this shrub, the plan pursued at present throughout most parts of England with regard to the Whitethorn is to be adopted. A bank of earth is to be raised 5 feet wide at bottom, $3\frac{1}{2}$ feet high, and 20 inches wide at top. At the proper season, which is in March, a drill is to be drawn on the top along the middle of the bank, and the seeds sown therein, and covered to the depth of 1 inch. In the course of two years the plants will begin to grow luxuriantly, spreading downwards on each side over the bank, so as to almost cover the whole of its surface. This fence should be regularly clipped once a-year, between November and March, and, of course, the particular time will be regulated by the demand for the clippings as fodder.

Hedges for Situations where the Soil is damp and boggy.

For this section Nature seems to have given us no trees or shrubs remarkable for their stability or rigidity. They are all soft-wooded, without prickles, open growers, but compensating for those deficiencies in the quickness of their growth. With such materials it is clear that an open ditch is an important and indispensable accompaniment.

The Elder.—This tree is remarkable for the ease with which it may be cultivated, its rapidity of growth, and the cheapness attending its formation into a fence. Trenching the ground in this case may be dispensed with, for, if the soil is dug over one foot deep, the roots will find their way into any damp soil. Even rooted

plants need not be used, but cuttings or truncheons inserted instead of them. A ditch should be cast as a fence on one side, and the soil taken out of the ditch should form a bank on the other. This hedge should be trimmed with a hedge-bill at the end of the first year, and every subsequent year, as recommended for the others. In such parts as have failed, fresh plants with roots should be inserted in the ensuing autumn, and at the end of three years the bank may be removed.

The Lombardy Poplar and the Black Italian Poplar.

Both these trees are admirably fitted as fences in moist soils. Plants one year old, which are generally about 4 feet in height, may be had at the nurseries at 1d. each, and these will form a tolerable hedge the first year. If the soil is dug over and manured several months previous to planting, strong cuttings may be inserted about a foot apart, and these will make shoots varying from 3 to 5 feet in height during the first season. At the end of the second year, during the month of November, the top of the fence should be regularly reduced with a hedge-bill to the height of 5 feet. This will strengthen the sides of the fence, and, consequently, increase the stability of the stems. A very good plan is to tie rods of wood to the young trees at 2 or 3 feet from the ground, until they have become sufficiently strong of themselves to resist the pressure of cattle. When properly attended to, by keeping them free from weeds, and trimming them regularly every autumn, those fences become highly useful and ornamental, and are at once amongst the cheapest and readiest of any that can be raised. The form of the hedge should be the same as that of the Hawthorn, only a little wider at bottom, and trimmed up in a wedge-like shape, as already explained, under the head of Whitethorn hedges.

The Alder.—As a hedge plant, the Alder is not so good as the Poplar; but as it is the most aquatic British tree that we have, it is worthy of being mentioned here as suitable to a class of soils and situations in which the Poplar will not grow freely. It delights in wet swampy lands, and will grow tolerably even in the water. The plants for fences should be four years old, not more, because when older they are generally devoid of branches at bottom. They may be set at a foot apart, and treated in every respect like the Poplar, trimming the fence with a hedge-bill, and keeping it at the height of 5 feet. The Alder will make a strong branchy fence, though not very close, and if pruned regularly as directed, it is susceptible of a neatness in appearance much beyond what is generally believed of it. Few have the courage to keep it in subjection, being a tree of extraordinary exuberance, and striving for the first few years to put forth a leader, or, in other words, to assume its tree-like shape. Afterwards, however, it seems to get reconciled to the form of the fence, which is to be accounted for by its producing, after repeated prunings, smaller spray or branches, which are more equally supported with nourishment and become luxuriant all over.

The Goat Willow.—As everyone knows, the Willow generally is a quick grower, and delights in moist land; but it by no means follows that every Willow is alike suited for fences, for very few of them are rigid enough to resist any pressure. I have, therefore, selected the species which possesses the requisite quality in the highest degree; and, as it is not always known by the name of the Goat Willow, I may mention that it is called the Black Sallow, and in the north of England the Saugh. In spring it puts forth beautiful yellow catkins or blossoms before the leaves appear; those flowers are gathered by children on Easter Sunday, under the name of "Palms;" and it may help some persons to the right species, when I inform them, that the first time bees are seen abroad in the spring is when on their way to the flowering branches of this tree. The best and cheapest way to form a fence of this tree is to procure a number of straight shoots, two or three years old, about 6 feet in length, and insert them in the soil to the depth of 15 inches, and at the distance of 18 inches from each other, crossing the rods at right angles. This will form a pretty good hedge even the first year; and by trimming it with the hedge-bill, as recommended for the others, it will be strong enough at the end of the second season to be left unprotected as a fence.—*Journal of the Royal Agricultural Society.*

BLASTING TREE STUMPS WITH DYNAMITE.

DYNAMITE consists of the explosive and, in its pure state, unmanageable liquid well known as nitro-glycerine, admixed with a very fine infusorial earth until a soft pasty mass is formed, which is inclosed in vegetable parchment so as to form cartridges about an inch in diameter by 6 inches in length. The advantages of this explosive material, in addition to its immense power, consist in the fact that it is not acted upon by water, and is practically far more safe than any other explosive agent known. Set on fire by a light it burns rapidly, like a paste made of wet gunpowder, but without giving off so many sparks or opaque smoke. A cartridge placed on

the section of a tree trunk may be smashed by blows of a sledge-hammer without exploding, nor is it capable of being exploded by any ordinary concussion; hence it may be safely carried about without any very special provision for safety. To ensure the explosion of dynamite, it must be fired with a detonating fuse, when it explodes with enormous power—ten or twelve times greater than that of gun-powder. Practically its detonation is effected by attaching a specially-prepared percussion cap on to the end of a fuse, of greater or less length as may be required, and firing the latter—the length being adjusted so as to give time for the operator to reach a place of safety. Fired thus on the ground in the open air, a single cartridge gives rise to a very loud sharp report. One experiment was performed on the stump of a huge Oak, above 6 feet in diameter; the auger holes for the separate cartridges, which should have been employed so as to enable the cartridges to rend the stump piecemeal had not been made; consequently, a heavy iron crowbar was employed to make a hole under the roots, and in this the cartridges were placed. When fired, the entire mass of tough Oak timber was rent and fissured in every direction, and the explosion of a few more cartridges rendered its entire removal a comparatively easy task. As the soil under the stumps is of less resistance than the tough Oak roots, the cartridges should not be fired in that position; but auger holes should be bored into the timber, into each of which a single cartridge should be placed, and in this way the root broken up in detail. With regard to economy of the use of dynamite, it may be roughly estimated that the cost of grubbing up and removing Oak stumps cannot be taken at less than 20s. each, which considerably exceeds in most districts the value of the wood for fuel. The dynamite cartridges are sold at 2s. per pound, and weigh each about 2 ounces. The value of the caps and fuse required is almost nominal. Hence, if one or even two dozen cartridges were required to blast a stump, the saving of expense and labour would be very great; but, in fact, with ordinary stumps and cartridges properly applied, a much less number would be required. The chief advantages claimed for the use of dynamite over gunpowder are the great economy of labour in boring—labour, not powder, being the great expense in blasting operations. With dynamite, smaller and fewer bore-holes are required, and as it requires no tamping (loose sand, clay, or even water being sufficient), there is thereby almost perfect immunity from accidents, as well as saving of time and expense. Great facility and efficacy in blasting under water and in damp situations; the absence of smoke; perfect safety in the handling, transporting, and storing of it. Although thousands of tons of dynamite have been used, there is no accident from it on record whilst in transit or storage, and none have occurred except through unwarrantable carelessness.

The Plaited-leaved Guelder Rose (*Viburnum plicatum*).

—This is a marvellous improvement on the common Guelder Rose, and deserves a place in the conservatory in April and May. The *Viburnums* are not easily forced early. There are few hardy plants that need more heat or longer time to induce them to flower out of season. In this respect they resemble the common *Syringa*, or Mock Orange. Place either of these in heat with Lilacs or Laburnums, and they will take almost three times as long to open their flowers as either; but, when they do open them, they remind one of summer rather than early spring. The blooms of *V. plicatum* are especially pure and beautiful; the leaves, too, are exquisite, and very different in form from those of the Guelder Rose. Mounted singly, the flowerets are admirable for the making of bouquets and in trusses, exquisite in vases or in baskets, while in pots the plants themselves look well either in the conservatory or drawing-room. In the open air, again, they are most useful, coming in on the heels of the Wild Cherry and the May, and when the profusion of white-flowering trees and shrubs is on the wane. Hardly any plants are more serviceable in shrubberies than *Viburnums*, and none of these are equal to *V. plicatum*.—D. T. FISH.

New Avenue Trees.—For avenue planting, those two near relatives, the Cucumber tree (*Magnolia acuminata*) and the Tulip tree (*Liriodendron tulipiferum*) combine many excellent qualities. They are rapid growers, beautiful in foliage or flower, of perfect form; hardy, excepting in the extreme north, not particular about soil or situation, and comparatively free from insects and diseases. They are readily grown from seeds, gathered and sown at once in the autumn, or, as some prefer, preserved moist until spring. When two years old, they are generally sufficiently large to plant out with a protection, or, if intended for the street, they may be cultivated in nursery rows for three or four years until they are tall enough to be beyond the reach of animals. A long line of either of these trees forms a magnificent sight when in bloom; and, for shade combined with beauty, will satisfy the most fastidious. One of the greatest

mistakes in street-planting is the selection of improper trees; for instance, a first-class tree, such as we have named, for a narrow street, and a small slow-growing species for a wide avenue. Each are equally out of place, and never look appropriate, no matter how handsome the individual specimens may be. The *New York Tribune* recommends these trees for avenues, and they seem to us equally suitable for the purpose here, both trees growing admirably with us. There are fine specimens of the Cucumber tree at Dropmore, and in many other English gardens.

Pear-leaved Guelder Rose (*Viburnum pyrifolium*). This very handsome shrub, which is hardly known outside the precincts of some botanic gardens, deserves to be extensively planted in pleasure-grounds and shrubberies, on account of the beauty of its broad corymbs of innumerable white and slightly fragrant flowers, the attractiveness of which is still further enhanced by the feathery appearance of the long projecting stamens, each tipped with a large yellow anther, which contrasts pleasingly with the pure white of the petals. The leaves are opposite, deciduous, oval in shape, very finely toothed, shining on the upper surface, smooth on both sides, and borne on short slightly winged stalks, not quite half-an-inch long. The plant is a native of North America, and is perfectly hardy, bearing our winters uninjured. It is easily multiplied from seed, which should be sown in peaty soil, and which germinates readily, especially if it is sown soon after it is gathered.—M.

Remarkable Trees near Maidstone.—Of these a few were mentioned by Mr. Kingsford, in a lecture which he delivered the other day before the East Kent Natural History Society:—A Walnut tree, he said, planted by his grandfather 100 years since, is in girth 1 foot from the ground, 10 feet 6 inches, the longest limb from the trunk being about 40 feet, the height about 50 feet. A Mulberry tree, 50 or 60 years old, 1 foot from the ground measures 5 feet 6 inches, one limb is 31 feet, and the tree about 40 feet high. Another Mulberry tree, nearly 100 years old, split down, so that one half remains, measures round 1 foot from the ground, 6 feet 9 inches, and in height is 30 feet. A variegated Holly, 100 years old, now laden with berries, is in girth 1 foot from the ground 3 feet 9 inches, and 30 feet high. Two old Beurré Pear trees, little better than pollards, now both more than 100 years old, stand in the orchard; one is 9 feet and the other 8 feet 3 inches in girth.

An Old Post.—A few years ago I stayed with a friend over night toward the upper end of Long Island. In the morning, while looking about the premises, I was attracted by the venerable appearance of a Locust gate-post near a still more venerable barn. Kicking away the earth, I took my knife to examine the condition of the post at that most trying point for testing the durability of timber—between “wind and water.” “How does thee find the wood?” queried my friend. “Perfectly sound; no evidence of decay, either above or below the weather line. How long has it stood here?” “The farm was settled by Hollanders nearly or quite 200 years ago, and has always been in the family. My grandfather remembers the post when he was a boy, and it was then considered an old one. We have authentic data for more than 100 years at the least. It has outlasted three generations already, and for ought that now appears may last as many more. We consider the Locust the most durable timber grown on the island.” This testimony to the extraordinary lasting qualities of the wood of the Locust (*Robinia Pseud-acacia*) is contributed by ex-president Peters to the *Tribune*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Double Variety of Scarlet Currant (*Ribes sanguineum*).—I wonder this is not more generally grown than it is. We have a plant of it now in great beauty, the flowers resembling drooping racemes of tiny Daisies. They also hang much longer on the branches than the single ones, and are now most effective, while the others have run to seed. I also notice that the seed on the latter is much more plentiful this year than usual, owing, I suppose, to the flowering season being warmer than usual.—D. T. F.

To Protect Young Trees from Hares and Rabbits.—Tar the stems from the ground to the height of about 20 inches. If the plants are wanted for ornament, the following plan is better, if the extra expense be no objection. Instead of applying tar to the tree itself, stick three or four stakes round each plant at the distance of 9 inches or a foot from it, then tie a bit of fresh tarred line round the stakes at the distance of 9 inches from the ground. The tar (which is applied to the trees to protect them from hares and rabbits) should be mixed with an equal portion of manure, of about the same consistence as the tar, or perhaps it will injure some of the trees.—VANESSA ANTIOPA.

Growth of American Forest Trees.—Mr. Fletcher Carr, a well-known authority on the comparative growth of forest trees, gives the subjoined schedule of measurements, made twelve years after planting: “White Maple, 1 foot in diameter and 20 feet in height; white Willow, 1½ feet in diameter and 40 feet in height; white Ash, 10 inches in diameter and 20 feet in height; yellow Willow, 1½ feet in diameter and 40 feet in height; Lombardy Poplar, 10 inches in diameter and 40 feet in height; Chestnut, 10 inches in diameter and 20 feet in height; black Walnut and Butternut, 10 inches in diameter and 20 feet in height; while the different kinds of evergreens will make an average growth of from 18 to 20 inches in height annually.”

THE LIBRARY.

DOMESTIC FLORICULTURE.*

THIS volume will not only prove a welcome addition to the amateur's library, but will also contribute towards the progress of domestic floriculture generally. The book is well got up, and is illustrated with about 200 engravings on wood. Room, window, and balcony gardening is minutely gone into, followed by chapters on Propagation; Soils for Potting; Manures and Stimulants; Pots and Potting; Watering Plants; Ventilating and Heating; Insects which infest Window Plants; Gardening in Close Cases; Wintering tender Plants in Frames and Windows; How to grow Hyacinths in Water; Instructions for the Growth of Bulbs in Windows; Hanging-baskets for the Window and Balcony; Orchids for the Sitting-room; the Window Garden in Winter; Calendar for Window-gardening Operations. The second part of the work treats of Bouquets; Wreaths and Vase Decorations; The Arrangement of Fruit; How to Dry Flowers and Ferns for Winter Decoration; How to Colour or Dye Flowers and Foliage for Winter; Fern-frond Designs; How to Skeletonise Leaves and Seed-vessels; Leaf Printing; Church Decorations; Flowers for Cemeteries: and the third part consists of a very select descriptive list of Plants and Flowers suitable for all sorts of domestic ornamentation. We give below one of the illustrations from the chapter on the "Window Garden in Winter," a balcony-garden many may have noticed in Portman Square, which represents a pretty balcony-garden of Ivy and Yuccas. The following somewhat lengthy extract on church decorations will show the way in which such matters are treated:—

The first recollection we have of church decorations dates back to the time when it was considered sufficient to fill the ancient font at Christmas with an armful of Holly and Ivy, and to stick a few sprigs of Laurel, Holly, or Box in gimblet-holes bored in the tops of the old-fashioned high-backed pews. All the decoration our church received was then done by a grumbling old sexton in a couple of hours; but now the case is widely different, for we have Easter decorations, and harvest decorations, in addition to the time-honoured display usually made at Christmas, and each of these occupy fully a week, while most of the materials are in readiness (thanks to our fair friends at the Rectory) even before that time. Beautiful flowers, evergreens, and silver Immortelles may be used for Christmas or Easter; while for the harvest thanksgivings we can also use Corn, autumnal foliage, and fruits tastefully arranged. The decoration of temples with beautiful flowers dates back for centuries, while it is at the present time practised in nearly every civilised country in the world. In Mexico and Peru it is customary to place the most beautiful Orchids and other choice flowers on the altars and shrines; and the custom is also popular in various parts of India. Wreaths of Ivy and other evergreens are very useful in Christmas decorations, and are easily made on thick twine or cord. Small sprays or little branchlets are preferable to single leaves, as they go further, and are not so stiff and formal as those made with leaves stripped from the stems. To make a wreath, take a branch or spray of foliage, and

commence at one end of your cord. Lay the branch along the cord pointing towards the end from which you start, and just loop it round with a bit of thin twine. Now add another spray and loop it in the same way. This last loop should also just catch the base of the first spray or branch, so that by tying in this way every branchlet is looped round twice, and thus firmly secured in its place. Clusters of white Immortelles or scarlet berries alternately are very effective in wreaths of dark-green foliage. The twine used for tying should be

cut into lengths 6 feet long, and should be looped round the stems without cutting. Longer lengths than this will be awkward to draw through the noose. Green and variegated Ivies, Hollies, and Euonymus, make nice wreaths, as also do sprays of Portugal Laurel, Aucuba, Juniper, Thuja, Yew, Tamarisk, and Box. Light and graceful wreaths look well twined spirally round columns, or carried round the tracery of Gothic arches, or the mullions of large windows. For the altar-cloth nothing looks better than a simple cross of silvery Immortelles and Grasses. This should be large enough to stand out clear and bright; but the size will be regulated by the dimensions of the cloth itself. We have seen many devices tried for the decoration of the pulpit, but nothing is better than a bold cross or the monogram IHS (see illustration) either in white Immortelles or scarlet berries. Texts tastefully formed in foliage and berries look well on scrolls or shields; while neat wooden shapes may be used for initials, monograms, and pleasing geometrical designs, such as crosses of various shapes, circles, or stars. Any carpenter or model-maker will make them in a few hours. Some make these designs by glueing leaves and berries on pasteboard shapes. If the cloth is crimson or dark blue the Everlastings stand out clear and bright, and are then very effective. The flowers used in Easter or harvest decorations should be of graceful form, bright or distinct colours, and should be arranged so that the individual beauty of each blossom is seen in addition to the general effect.

All kinds of Lilies are very suitable, especially *Lilium speciosum* and its varieties. The foliage and flowers of the chaste Trumpet Lily (*Richardia æthiopica*) are unsurpassed for the altar, and last a considerable time after being cut from the plant. A good specimen of this plant, or two or three small ones placed together,

look remarkably well arranged on the font, especially if the latter is in a prominent position. Both flowers and foliage look remarkably well along with statuary or architectural details. If the pulpit, font, and pillars, are of white stone, they look well draped with the Virginian Creeper and Ivy, both of which should be allowed to droop unrestrained in elegant festoons of bright glowing crimson and green; while clusters of Apples, bouquets of Wheat and Oats, or bunches of Grapes, may be introduced here and there with good effect. The silvery or pale rosy plumes of the Pampas Grass and *Arundo conspicua*, mixed with branches of the Purple Beech, or the feathery foliage of the Sumach, when tinged with crimson in autumn, are very effective; and stems of *Arundo Donax* or Japanese Maize may also be used for variety. All these are bold and distinct, and look well massed in a picturesque manner along with the glowing scarlet flowers of the Scarborough Lily (*Vallota*),

the Guernsey Lily (*Nerine sarniensis*), or the delicate pink flowers of the Belladonna (*Amaryllis*). Group all your foliage and flowers as naturally as possible, and do not attempt anything in the way of unmeaning designs. Ladies, as a rule, do these kinds of ornamentation better than any one else, and seldom fail to make pleasing arrangements. It is as well to be careful in the use of yellow flowers, as many of these have a glaring or gaudy appearance, not in keeping with the quiet rich softness of colouring and peaceful

Balcony Garden in Portman Square.

* "Domestic Floriculture, Window Gardening, and Floral Decorations." By F. W. Burbidge. London and Edinburgh: W. Blackwood & Sons.

harmony of arrangement which should at all times prevail within a sacred edifice.

This is, we believe, the first book in which an attempt has been made to embody a really useful amount of information on this subject—one that is every day growing in importance. It is abundantly illustrated by the author's own pencil, and from other sources, and is a noteworthy addition to our garden literature.

THE EXHIBITION OF AMERICAN PLANTS IN RUSSELL SQUARE.

THE Rhododendrons which have so long adorned our London botanical and horticultural gardens have now come to Bloomsbury, and Russell Square this year has the good fortune to display the great annual Rhododendron exhibition of Messrs. John Waterer & Sons, of Bagshot. Far back, in old days, the Rhododendron ponticum, a native of Asia Minor and the Levant, was a well-known and familiar plant; and its generic Greek name, handed down from remote ages, has since been applied to relatives much more handsome, from America, India, and elsewhere. Amongst other traditions connected with the Rhododendron, is the supposition that the illness of the soldiers of Xenophon's army arose from their having eaten honey which had been collected from the Rhododendrons of the locality; although some writers apprehend that the cause of the mischief was the Azalea pontica, or the Oleander, the latter of which would seem to have shared with the Rhododendron the appellation of the Rose Bay. It seems singular that, notwithstanding its European origin, this Rhododendron ponticum should not have been introduced into this country till 1763, and that it should have been preceded by an American species, *R. maximum*, in 1730. The two Swiss species, *ferrugineum* and *hirsutum*, were introduced in 1752 and 1656 respectively; and other kinds, of more or less importance, appear to have reached England between these dates, and the introduction from North America of *R. catawbiense* in 1809, which was destined to be the precursor of our present garden treasures. Nothing further would seem to be specially worthy of comment, till we come to the period of the arrival of the great Indian tree Rhododendron (*R. arboreum*) in this country. This was indeed a great and valuable acquisition, but unfortunately too tender and delicate in its constitution to stand the severity of our climate unprotected. According to Loudon, this species was introduced in 1817. The original one, with flowers of a vivid scarlet, was subsequently followed by other varieties with rose-coloured and pure white flowers, and hybrids soon began to find their way into our collections. By and bye, through the patience and energy of hybridisers, the glowing colours of the Indian species began by degrees to appear amongst the seedlings which had been raised by careful selection and hybridisation of the best forms of Rhododendron *catawbiense* with *R. arboreum*, and the result may now be seen in the wonderful and dazzling effects of colour, form, and foliage which decorate our gardens and shrubberies. Many attempts have also been made to produce hybrids between Rhododendrons and hardy Azaleas, which did not, however, meet with any considerable success. The next era in the history of the genus was the introduction of numerous new and distinct varieties from the Sikkim-Himalayas, by Dr. Hooker, about 1850, and of the Bhotan species, by Nuttall. These, with the yellow, or rather orange, flowered *R. javanicum*, and other species from the East, though forming charming conservatory plants, are, with one or two exceptions, not suited for outdoor culture. To the improvement of our hardy Rhododendrons none have paid greater attention than the Messrs. Waterer, from whose fields of them at Bagshot and Knap Hill, pleasure-grounds everywhere have been enriched with kinds brilliant in colour and hardy in constitution. Those who have seen the increasingly magnificent displays at the Royal Botanic Gardens, Regent's Park, and Bagshot, for these last twenty-three years, need scarcely be reminded of this. In Messrs. Waterer's present exhibition, all the varieties shown are perfectly hardy, and have all, large as their number is, been recently lifted from the open ground. Many of them have heads from 25 to 30 feet in circumference, and balls of earth weighing from 12 to 16 cwt. Some idea may therefore be

formed of the labour and expense involved in bringing them from Bagshot to London, and planting them in their present well arranged beds. Few plants have attained the popularity which, from its first introduction, the Rhododendron has commanded. Nor is this surprising when we consider that it possesses qualities which render it essentially "everybody's" plant. In the first place, its perfect hardiness is a quality which can scarcely be too highly valued. As a proof of this, it may be remarked that many of the plants in the present exhibition have been subjected to the temperature of some of our severest winters without sustaining injury. Of its decorative uses it is unnecessary to speak; suffice it to say that for the flower garden or pleasure-ground, its presence either in clumps, shrubbery belts, or as single specimens, is indispensable; as a striking object on Grass, nothing can be more suitable than a fine well-grown Rhododendron, which, even without flowers, forms a pleasant object, and would, even were its inflorescence insignificant, still retain its value as a hardy, fine-foliaged evergreen. For planting as undergrowth and cover, it is of the utmost value, withstanding, as it does, the severest weather, always presenting a cheerful and pleasing appearance, and not being liable to sustain injury from hares or rabbits. It is, likewise, well adapted for forcing for the decoration of the conservatory. Many of the early-flowering sorts, in fact, if potted and placed in the greenhouse, will furnish an ample and early supply of bloom, without any forcing whatever. As town plants, many varieties will be found to be invaluable, as they not only seem to withstand smoke better than most evergreens, but flowers are also freely produced if care be taken that they are planted in fresh well-prepared earth. It is a mistake to suppose that a peaty soil is necessary for the growth of Rhododendrons and other American plants; on the contrary, they will succeed in almost any district, with a little careful preparation. It may not, perhaps, be out of place to remark that many other plants, usually associated with Rhododendrons, possess invaluable decorative properties, such as hardy Azaleas, Andromedas, Kalmias, Ledums, and similar ornamental shrubs; but nothing, perhaps, is more interesting than a collection of hardy Heaths. There is scarcely a month in the year during which they are not, more or less, in flower, and, therefore, they should form a prominent part in gardens of even limited extent. Russell Square, in which so much floral beauty may now be found, has been courteously lent by the Duke of Bedford and the Commissioners of the square for the occasion. It is 7 acres in extent and is one of the most agreeable and best kept open spaces in London. The tent, a double span-roofed one, is 220 feet in length, and consists of 22,000 feet of canvas. Some idea of the extent of the exhibition, and of the interest which it possesses for admirers of American plants, may therefore be obtained. During these last ten years or so, Messrs. Waterer have, by means of carefully selected parents, and patient crossings and inter-crossings, raised many beautiful kinds, among which, however, none are more striking than Kate Waterer, a charming new variety with bright rosy-pink flowers, blotched and spotted in the upper petals with greenish-yellow. The leaves, too, of this kind are large and fine, and, altogether, it is a valuable addition to the rosy-blossomed section. Strikingly pretty among older varieties are clumps of Lady Eleanor Cathcart; but in this department, amid so much floral splendour, it is needless to particularise. The novelty of the show in Russell Square has led us to speak mainly of that; it should be added, that Mr. Anthony Waterer has his usual magnificent display at the Horticultural Gardens, Kensington; and in Regent's Park is another Rhododendron show, furnished from the nurseries at Great Berkhamstead, by the Messrs. Lane. These displays are rich in interest, both as regards novelties and older kinds.

A FINE specimen of botanical phraseology is found in the Charter-house examinations for 1873, under the head of Botany, where the scholar is told to explain the following terms:—"Malva has a gamosepalous calyx, a polypetalous hypogynous corolla, polyandrous monadelphous epipetalous stamen, and a superior syncarpous pistil." Surely our scientific men can invent some less alarming mode of teaching what is usually considered the agreeable science of botany, than by questions of this character.

WORK FOR THE WEEK.

Flower Garden and Pleasure Ground.

THE planting of flower beds and borders should now be nearly completed, and, as soon as the confusion and litter of empty pots, &c., can be fairly got rid of, the Grass and gravel walks should be well swept and rolled, and the garden, in all respects, put in good order. The plants in the various beds should also have all necessary attention in the way of pegging down, staking, training, &c., and should all be well supplied with water, while the weather remains dry, and until they have become somewhat established. It is always advisable to put stakes to Dahlias as soon as they are planted; and Hollyhocks, Delphiniums, Phloxes, and other tall-growing herbaceous plants, should now have their stems somewhat thinned out if found necessary, and those selected to remain should be neatly tied to stakes. Bulbs of Tulips, Anemones, Ranunculuses, &c., should now be taken up and carefully stowed away; and a commencement should at once be made in the propagation or increase of spring-flowering bedding plants by inserting under hand-glasses cuttings of Pansies, Pinks, Wallflowers, and other plants, while the best varieties of Primroses, Polyanthus, Aubrietias, Forget-me-nots, &c., may be at once increased by division and planted in shady situations in the reserve garden. The season in many localities is decidedly unfavourable as regards the Rose garden, on account of the drought as well as the cold weather, which prevailed so long, and caterpillars and aphides now greatly abound, both of which should have immediate attention, as already directed. Ornamental trees and shrubs have, in many cases, suffered severely from the late frost. Walnuts, even now, have the appearance of being quite dead, their young shoots, some 6 or more inches in length, being killed back to the old wood; and this, it may be feared, will greatly check the progress of young trees. In the meantime, it might be an advantage to have the dead shoots at once removed. Remove rival leaders from young trees of the Cedar of Lebanon, Deodar, and other Coniferous trees, where they exist, retaining the strongest, and such as are most favourably placed. Where an undue tendency exhibits itself towards lateral extension, this should also now be checked by stopping, or even cutting back, strong growing lateral branches. In the hardy Fernery, many specimens will soon be in their greatest beauty, and should, therefore, have their share of attention. The fresh green fronds of various species are frequently disfigured by slugs and snails, both of which should be carefully searched for and destroyed. Vigorous specimens of *Osmunda regalis* should have an abundant supply of water.—P. GRIEVE, *Culford Gardens*.

Hardy Flowers.

Vigorous perennials, such as *Lavatera thuringiaca*, *Althæas*, *Heracleums*, some Larkspurs, *Polygonums*, various members of the Composite family, &c., have, during the past week, made rapid growth, and will therefore require further attention in the way of staking, as will also plants of medium height, such as the hybrid Phloxes, Pyrethrums, Pentstemons, &c. Seeds of any choice plants just arrived should be sown at once, either in the open air or in pots, selecting for the latter such as are delicate or diminutive. Plant out annuals raised in pots as soon as they are strong enough to handle, and make fresh sowings in the open ground of such kinds as *Collinsias*, *Nemophilas*, *Eschscholtzias*, *Silene pendula*, *Candytufts*, *Malopes*, &c., for successional blooming; attend, also, to the thinning of those previously sown. Pot off seedlings of perennials raised in pots as soon as they are fit, using for the purpose a sandy compost, and put three seedlings into what are known as thumb-pots, placing them round the edges. In the case of strong-growing kinds, however, one seedling in a pot will be quite sufficient. Seedlings of the commoner perennials should, however, be pricked out into the open border, selecting a shady spot or one over which a shading may be easily placed, until they have become established. Continue to propagate, by means of cuttings, such plants as it is not practicable to divide. Keep a sharp look-out for the seeds of early-blooming plants, and gather them as soon as ready. Where a stock of plants is kept in store-pots, these should be plunged in sand or ashes in the open air. The splendid weather which we are now experiencing has induced a large number of plants to come into flower, while some of those that have been in blossom for several weeks past have made considerable improvement; the display usually made by the Iris tribe has, however, been greatly impaired by the coldness and dryness of the past month. The undermentioned plants, among others, are particularly striking at the present time, viz., the pretty dwarf *Hutchinsia alpina*, a mass of white bloom; *Æthionema orientale*, a showy Cruciferous plant about 18 inches high, which bears an abundance of light rose-coloured flowers; the single and double white Sweet Rockets or Dames Violets are also very showy plants at the present time; the last, an old variety, is but too seldom seen, its pure white flowers, which are produced in abundance, forming a fine contrast with the purplish-

red blossoms of the common form; *Achillea umbellata*, usually grown for the sake of its silvery foliage, is producing white blooms in such quantity as to make it a desirable plant for floral display. Several forms of *Aster alpinus* are blooming freely, and the beautiful blue flowers of *Linum narbonneuse*, borne in great profusion, are now particularly conspicuous. The blooms of several hardy bulbs now add considerably to our outdoor display, particularly those of the Martagon Lilies, *Alliums* (of different sorts), *Muscari comosum plumosum*, and *Scilla peruviana*. Plants of *Veronica pinguifolia*, a dwarf shrubby species, are now clothed with pretty white flowers. *Tropæolum polyphyllum*, a valuable plant for trellises, rock-work, banks, or fronts of houses, has also just commenced to produce its showy pale orange blossoms.—T. SPANSWICK.

Cool Orchids.

Potting may still be continued, for it should be borne in mind that success is more likely to be the result of potting plants individually, just as they require it, than when subjecting the whole collection to the operation at any one time. The pots should be at least half full of crocks, and the best compost to employ is one composed of turfy-peat, fresh living Sphagnum, and sufficient coarse grit to keep the whole porous. A little fibrous loam may be added with advantage in the case of strong growing kinds. Give air freely in hot weather, and shade during bright sunshine. Syringe freely morning and evening, and keep the floors, shelves, and benches constantly moist. Plants on blocks, as *Sophronis*, *Oncidium cucullatum*, *Lælias*, *Barkerias*, and others should be plunged overhead in a tub or pail of tepid water daily, so as to moisten the whole mass thoroughly.—F. W. BURBIDGE.

Hardy Fruit Garden.

What relation there can be between east winds and aphides it would be difficult to say; but if not cause and effect, as many affirm, assuredly the two are coincident, or seem to be so. Aphides are plentiful this season, and not a moment must be lost in clearing the trees of them. There are two general methods of doing this—the one poisons, the other removes them bodily, either by hand-picking or washing. It is astonishing what can be done by picking if begun in time. The garden engine, if skilfully used, is at once prevention and cure; it prevents the aphides from getting a footing, and washes them off clean if they do. The use of poisons, whether tobacco-water, quassia, Foxglove, or Laurel-tea, or Gishurst, or other compounds, is to kill the insects as they feed, and render the leaves so nauseous and poisonous that they will not eat them. The great point is to be prompt with both remedial and preventive measures. It is of no use to let the aphides destroy the leaves before we remove them. By killing the first insects we save our trees. They, however, appear in successional swarms; so it will not do to rest in security after one or two raids; our eyes must be on the trees throughout the growing season, and we must be ready at a moment's notice to renew the struggle with our insect enemies. If white bug appears on Apples, touch the infested parts with turpentine, keeping it, of course, off the leaves, fruit, and young wood. Caterpillars, also, often infest Apples, and will be found in bunches which often include some of the young fruit, that will speedily be devoured by the young grubs, if not removed. The Gooseberry caterpillar is also abroad. Select a dewy morning, or an opportunity after a shower, should one fall, to dust the leaves over with a half-and-half powder of air-slaked lime and Hellebore, peppering the caterpillars as heavily as possible. Within a week, or less, engine the bunches clean with a stream of water. It will be safer, however, not to gather any green Gooseberries for tarts or bottles from the poison-dusted trees; Foxglove tea is equally effective, and about equally poisonous. Hand-picking, if adopted in time, is better than either, or a 6-inch thick dressing of spent tan in winter is a sure preventive. It either smothers the larvæ by keeping them in, or kills them with the tanin left; either way, it is a perfect cure, or rather a complete antidote against Gooseberry caterpillar. The Gooseberry crop is a very general failure this year, which will, doubtless, prove a serious sanitary and monetary loss to the country. The temptation will, therefore, be strong, in many cases, to let the caterpillars have their way; this, however, would be to invite the loss or deterioration of next year's crop as well as this; and it is, therefore, to be hoped that special care will be taken to keep the bush-fruit clean; and thus prepare it for yielding a good return in the, it is to be hoped, more genial weather of next spring.—D. T. FISH, *Hardwick*.

Kitchen Garden.

At this season, in many places, the kitchen garden is subordinate to the ornamental department, but neglect now, either in keeping down weeds or in performing the necessary operations of sowing and planting successional crops, will certainly entail disappointment in time to come; therefore, make every possible effort to keep pace with

the season. Celery trenches should be prepared at once for the main crop. In dry porous soils—what is termed the bed system is an excellent plan, especially for autumn use; open a trench 4 or 5 feet wide, any length desired, casting the earth to each side in about equal proportions, place 6 inches of rotten manure over the bottom, fork it in, and cast on a little fine soil; the planting is best done in dull showery weather, or, failing that, in the evening or early morning. For the convenience of earthing up, plant the rows across the trench, 1 foot apart, and the plants 9 inches apart in the rows. As I have already stated, this is an excellent system for dry porous soils, as it economises both land and labour; but in heavy retentive land it is better to plant in single rows 4 feet apart, or double rows at 6 feet intervals. This mode of planting offers facilities for banking up the earth to throw off heavy rains; there is, also, a freer circulation of air amongst the foliage than would otherwise be the case, and, consequently, less tendency to decay, which, where quality is a first consideration, will compensate for the larger space occupied. On heavy soils, Celery trenches should not be made too deep, especially for winter use. Early Celery now in trenches must have unremitting attention as regards watering, as any check from drought would cause it to bolt, and be useless. Liquid-manure should also be given as often as it can be obtained. The time may come, perhaps, when the sewage, that is now worse than wasted, may not only be rendered innocuous to health, but be made available for vegetable culture. Until that time arrives, a very serviceable liquid-manure may be made suitable for any crop by dissolving from 1 lb. to 1½ lbs. of guano in a barrel of water, which may be given with good effect once or twice a week, in dry weather, to such crops as Celery, Cauliflowers, Lettuce, Radishes, &c.—not a mere dribble, but a thorough soaking. To ensure whiteness and delicacy of flavour, all Lettuces should be tied up a week or so before they are required for use; even the Cabbage varieties are improved by it. Sow for succession, thinly on a cool north border, once a fortnight, in drills 1 foot apart, to be thinned—the larger Cos and Cabbage Lettuce to 1 foot, and the smaller varieties (like Tom Thumb) to 8 inches apart in the rows. Mulch between the rows with short manure; then, when it becomes necessary to water, the moisture will be retained. The same treatment is also beneficial to Radishes, as regards ensuring quick growth, and, consequently, mild crisp roots. Sow small salading once a week; and, after watering, cover the bed with Rhubarb-leaves, laid down flat on the soil, to keep the soil cool and moist without an incessant use of the watering-pot. As there are usually plenty of Rhubarb-leaves at this season, any small seeds it may be necessary to sow in dry weather may be advantageously covered with such leaves till they come up.—E. HOBDAV.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 4TH.

THIS exhibition may be classed amongst the best of the year, nearly all the classes being well contested, and Mr. Anthony Waterer's exhibition of Rhododendrons certainly added greatly to the attractions of the occasion. Stove and greenhouse plants, Ferns, and Orchids were well represented, and new plants were never, to our knowledge, shown in better condition. The show of fruit was hardly so large as we had anticipated, but what was shown was good, more especially that in the classes for Strawberries, Peaches, and Grapes, while Pines were of average merit.

Stove and Greenhouse Plants.—Of these, Mr. Ward staged a fine group, consisting of a fine *Erica tricolor impressa*, fully 4 feet across; a fresh *Genetyllis tulipifera*, with a profusion of richly-coloured flowers; and a finely grown and well bloomed plant of *Ixora amboynensis*, with foliage in beautiful condition and immense trusses of bright orange flowers; the specimens of *Aphelaxis macrantha purpurea* and *Erica Cavendishii*, were as perfect as could be desired, and a well-bloomed plant of *Bougainvillea glabra*, shone conspicuously, on account of its novel colour. In the nurserymen's class, Messrs. Jackson had a finely finished group, the most notable specimen in it being a *Stephanotis floribunda*, about 4 feet by 4, and a superb specimen of good cultivation; the same collection also included fine plants of *Anthurium Scherzerianum* with brilliant scarlet spathes; and remarkable examples of *Dracophyllum gracile* and *Ixora coccinea*. Mr. B. S. Williams was second, with a remarkably fine group, in which were two magnificent *Azaleas*, and a large *Anthurium Scherzerianum*, with about fifty spathes. In class 1, Mr. Ward had a fine *Erica depressa*, *Aphelaxis macrantha rosea*, a very large-flowered variety, well worth growing for show purposes on account of its novel colour. This group included three fine *Heaths*, viz., a splendid plant of *Erica Cavendishii* nearly 5 feet through, and one of the finest plants of the soft rosy-flowered *E. tricolor Kingstonii* that we have seen, while *E. Candolleana* was a perfect example of how an *Erica* should be grown and flowered for show purposes. Mr. Wheeler, of Stamford Hill, was second with a very fine group, in which were fine specimens of the sombre-tinted *Erica depressa*, *E. Cavendishii*, and a good *Clerodendron Balfourii*. The eight stove and greenhouse

plants shown by Mr. Baines, for the "Davis Prize," were models of good cultivation. Where all are good it is difficult to particularise, but the plants of *Dipladenia amabilis*, *Ixora coccinea*, *Bougainvillea glabra*, and *Ixora aurantiaca*, deserve especial note. Mr. Kemp, gardener to the Duke of Northumberland, was second with a nice group; and Messrs. Cutbush & Sons third. There appeared to have been some little misunderstanding, the latter exhibitor having staged two plants of the same species; but, after reading the rules, we are not aware that such a course is prohibited. For six *Dracenas* Mr. Bull was first with well-grown plants of *D. Fraserii*, *D. Baptistii*, *D. Goldiana*, *D. Chelsonii*, *D. amabilis*, and *D. Mooreana*. Mr. J. W. Wimsett was second with a group of fresh well-coloured plants.

Ferns.—These were well represented, and the first award for eight went to Mr. T. Shuttleworth, of Preston, who had a noble plant of *Todea superba*, about 2 feet across, and remarkably fresh; *Gleichenia rupestris*, the bright green *G. flabellata*, and two fine pots of *Leucostegia immersa*, and *Davallia Mooreana*, one of the noblest of all Ferns when well grown. In the nurserymen's class, Mr. B. S. Williams was deservedly awarded the first prize for *Gleichenia rupestris*, *Adiantum Farleyense*, *Dicksonia fibrosa*, a species similar to *D. antarctica* in general habit, but quite distinct; and a fine *Cyathea dealbata*, a kind well known on account of the silvery hue presented by the under sides of its ample fronds. In the class of twelve hardy Ferns, Messrs. Ivery & Sons were first, with well-grown plants; Mr. Stone, gardener to C. Walton, Esq., being second, with nice plants of *Adiantum pedatum*, *Onoclea sensibilis*, *Osmunda regalis*, and others. Mr. R. Parker, of Tooting, was third, with fresh healthy plants, in good condition.

New Plants.—Mr. Bull, who was first, had fine specimens, among which were a splendid plant of *Phyllotaenium Lindenii*, with immense heart-shaped leaves and conspicuous ivory veins. This is one of the finest of ornate *Arads*, and one which deserves a foremost position in every stove; also, a well-coloured plant of *Croton majesticum*, with long pendant crimson and yellow-tinted foliage. *Anthurium crystallinum*, with fine velvety green foliage and broad silvery veins. This is a worthy companion to the *Arad* first mentioned, and far superior to its allies on account of its dwarf dense habit. Mr. Bull also had *Pritchardia grandis* *Campsidium filicifolium*, an elegant climbing plant, with fresh crisped pinnate leaves; and *Dracena amabilis*, in the way of, but superior to, the now well known *D. Guilfoylei*. The group also included *Kentia Moorei*, a dark green pinnate Palm, which promises to be extremely valuable when better known; a plant of *Dipladenia Brearleyana*, bearing several of its brilliant crimson salver-shaped flowers, *Aralia Veitchii* and *Croton Wisemanni*, the whole forming one of the best-grown groups of novelties ever staged. In the class for six new plants, Mr. Bull obtained the only gold medal awarded, with a fine *Pritchardia grandis*, one of the finest of all fan-leaved Palms; *Croton spirale*, a dark bronzy-green species, the foliage of which is curiously contorted or twisted like a fanciful corkscrew; *Croton majesticum*; *Maranta Leopardina*, the latter a bright green-leaved species, having regular oblong blotches of a dark glossy green colour on each side the mid-rib; *Dracena Goldiana*, a kind with large ovate foliage marbled with silvery-grey in a manner not unlike some varieties of *Phalaenopsis Schilleriana*. The most attractive plant in the group, however, from a gardener's point of view, was, undoubtedly, a fine well-flowered plant of the new *Dipladenia Brearleyana*, which has flowers fully 5 inches across, of the most vivid crimson-scarlet when fully developed, the youngest flowers being of a pale rosy tint. In the competition for Mr. Bull's prizes, awarded for new plants sent out since 1871, Mr. J. Wimsett was first in the nurserymen's class with excellent specimens of *Maranta Mackoyana*, *Dracena Fraserii*, a deep leaved species; *Curculigo recurvata variegata*, recently figured in our columns, and others. In the amateurs' class for new plants sent out by Mr. Bull since 1871, Mr. T. Shuttleworth, of Preston, was first with a unique specimen of *Cyathea Burkei*, a kind figured in THE GARDEN at p. 271, Vol. IV.; *Dæmonorops palembanicus*, one of the most elegant of pinnate-leaved Palms; a splendid specimen of *Vriesia reticulata*, and good plants of *Dracena Fraserii* and *D. Shepherdii*. Mr. J. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, had a well-grown group, to which the second prize was awarded; Mr. J. Coombe, gardener to Col. Wilkinson, Highgate, was third with a nice group of smaller plants. Messrs. James Veitch & Sons certainly deserved the thanks of the society and horticulturists generally, for the magnificent group of new and rare stove and greenhouse Palms, Ferns, Orchids, and other decorative plants, which they contributed. This group was remarkable alike for the beauty of the individual specimens, and for the artistic and natural manner in which they were arranged. Among new Orchids included in it we remarked *Cattleya gigas*, a noble species, now shown for the second time; *Dendrobium Bensoniæ*, remarkably well bloomed; *Cypripedium argus*; a splendid panful of *Masdevallia Harryana*, the brilliant crimson flowers being contrasted with the pearly *Odontoglossum Alexandræ*, *O. Pescatorei*, and the elegantly fringed sweet-scented *Dendrobium Devonianum*. Other novelties consisted of *Ficus Parcellii*, *Lomaria zamiioides*, *Begonia Chelsoni*, and *B. vesuvius*, *Paullinea thalictrifolia*, *Geonoma gracilis*, *G. Martii*; fine cut specimens of *Fremontia californica*, with deep green lobed foliage and bright golden flowers, each as large as half-a-crown; a figure of this fine tree will be found in THE GARDEN, Vol. III. p. 55; a plant of *Darlingtonia californica* had fine highly-coloured pitchers, and the same may be said with regard to *Cephalotus follicularis*.

Orchids.—These were very fine, and in good condition. Mr. B. S. Williams, who was first in the nurserymen's class for twelve species, had a fine plant of *Orchis foliosa*, bearing about twenty fine flower-spikes; *Cattleya Mossiæ*, well-flowered, and suggestive of the fine plants staged by Mr. Bullen some years ago; *Cypripedium barbatum superbum*, with

about forty fine flowers; *Cattleya Warnerii*, *Lælia purpurata*, and others. Mr. W. Bull was second, with smaller, but well-flowered plants, conspicuous among which were *Odontoglossum Rœzlii*, with two spikes, a charming species, and one deserving of general culture; *Cypripedium Parishii*, *Cattleya Mendelii*, the pretty little *Palumbina candida*, and others. Mr. E. Morse had a dozen well-grown and nicely-bloomed plants. In the amateur's class, Mr. Ward was first, with a group in which were fine specimens of *Cattleya Mossiæ*; *Odontoglossum Phalænopsis*, with about twenty flowers; *Phalænopsis grandiflora*, with seven or eight fine spikes; a good *Cypripedium Stonei*, with four good spikes; a fine *Odontoglossum Alexandræ*, and others equally well-grown. Mr. F. Rutland, gardener to the Duke of Richmond, was second, with a nice group in which were a fine *Cattleya Mossiæ magnifica*, a remarkably flat-petalled deeply-tinted variety, *P. Mossiæ superba*, a variety with pale crisped petals and a richly-veined lip; *Cypripedium caudatum*, bearing five large and richly-tinted flowers, the tail-like petals being of extraordinary length; and a plant of the old *Dendrobium nobile*, fresh as could be desired and well bloomed. Mr. J. Douglas, Loxford Hall, was third with a small but really select and well-flowered collection, in which were *Cypripedium villosum*, *C. Veitchii*, *Masdevallia Harryana*, with ten large and richly-tinted flowers; a nice plant of the chaste *Dendrobium Bensoniæ*, well-bloomed; and a well-grown plant of the old *D. formosum*.

Foliage Plants.—In the class of nine, Mr. J. Hudson, Champion Hill, Camberwell, was first with a fine group, in which were *Zamia villosa*, a graceful and permanent plant, well worth culture; a splendid *Croton pictum*, remarkably well-coloured; *Areca sapida*; and one of the finest plants of *Stevensonia grandifolia* we have ever seen exhibited. Mr. T. Shuttleworth had eight fine foliage plants, including a fine large form of *Sarracenia flava*, *Gleichenia dicarpa*, *Cocos Weddelliana*, *Nepenthes Rafflesiana*, *Dicksonia squarrosa*, and others. Mr. Donald was second, with a well-grown group. Mr. W. Cole, of Ealing Park, was third, with nice plants, among which were *Chamærops humilis gracilis*, *Croton pictum*, *Lomaria gibba*, *Pandanus elegantissimus*, one of the best of green-leaved Screw Pines, and *Yucca aloefolia variegata*.

Roses.—Messrs. G. Paul & Sons, of the Old Nurseries, Cheshunt, had a nice group of eight plants, well flowered. Conspicuous amongst them were *Souvenir d'Elise* (a fine cream-coloured Tea) and *Madame Margottin*, a good and well formed sulphur-tinted variety of the same class. Associated with these were also Miss Ingram, one of the best of the light-coloured kinds, and Dupuy Jamin and Marie Rady, both rich-coloured varieties worth attention. Mr. Chas. Turner, of Slough, also had a nice collection.

Pelargoniums.—Fancy kinds were well represented. Mr. James, of Isleworth, had six perfect specimens, including *Princess Teck*, white and rose; *Lucy*, rich deep rose; and *Ellen Beck*, a beautiful soft rose. Second, Mr. Ward, who also had fine plants. Third, Mr. D. Donald, Leyton. In the class for large-flowered kinds, Mr. Ward was first with fine plants. Second, Mr. James with smaller well-bloomed plants. Third, Mr. J. Wier, the Elms, Hampstead. In the nurserymen's class for fancy Pelargoniums, Mr. Charles Turner, of Slough, was first with a fine group.

Succulents.—First, Mr. J. Croucher, gardener to J. Peacock, Esq., who had a fine group, including *Echinocactus visnago*; *E. Cummingii*, with very showy golden-yellow flowers; *Echeveria pulverulenta*, one of the most remarkable species in the genus; *Agave laticinata*, and the still more rare and valuable *A. eusiformis*, belonging to the *A. striata* group. Mr. C. Pfersdorff, also had a nice healthy group.

Miscellaneous Subjects.—Messrs. Downie, Laird, & Laing had a fine group of Ferns, Palms, Succulents, and bedding plants. Mr. Robert Parker, of Tooting, staged a fine collection of hardy herbaceous plants, British Ferns, and cut blooms of Iris and other hardy flowers. Mr. Parker also obtained first prizes for collection of Pyrethrums, Hardy Perennials, and Pæonies in pots, as well as for a fine collection of cut flowers, neatly arranged in pots of wet sand. Messrs. Hooper & Co., of Covent Garden, staged a splendid collection of *Ixias*, *Sparaxis*, *Anemones*, *Lilies*, *Iris*, *Ranunculus*, and other hardy flowers. Mr. Voice exhibited two or three forms of his improved garden frames. Mr. Charles Noble furnished *Spiræa palmata*; Mr. Bull a group of Crotons, Ferns, and Cycads; Messrs. Ivery & Son a collection of British Ferns in fine condition; Messrs. Standish Tuberoses, Pinks, and *Bouvardia Humboldtii corymbiflora*, and other plants for cut flowers. Mr. Cutbush Ives in small pots, neatly set up in boxes; Mr. B. S. Williams, Holloway, had a group of decorative plants and Orchids; Mr. Bull received a first prize for twenty fine foliaged plants; second, Messrs. Rolisson, for *Platynerium grande* and *Adiantum Farleyense*. Messrs. Carter had a fine bank of Crotons, Ferns, Palms, Cycads, and other decorative plants. Mrs. Murdoch, of Milford, Godalming, exhibited three cases of skeletonised foliage and seed vessels, which were very much admired. Messrs. Backhouse furnished a plant of *Sobralia macrantha nana*, which is similar in habit to the form called "*Wooleyii*," the flowers are, however, slightly larger, and the leaves appear to be more lance-shaped than those of that kind. Mr. R. Dean had a fine collection of double Stocks, the colours varying from white to the deepest crimson; also a plant of the Irish Butterwort, *Pinguicula grandiflora*, a delicate little Alpine gem, with apple-green leaves, and bright purple flowers nearly as large as those of the old *Streptocarpus Rexii*. Messrs. Jackson, of Kingston, had a fine basket of *Saxifraga nepalensis*, with oblong leaves, margined with a row of pearl-like dots, and bearing large panicles of snowy-white flowers, fully 2 feet high.

Fruit.—In the class for two Queen Pines, Mr. T. W. Bond, gardener to G. A. Smith, Esq., Weybridge, Surrey, was first with nicely swelled fruit, weighing 4 lbs. 10 ozs. each. Second, Mr. J. Gray, Grange Park, Alresford, Hants.—Two smooth Cayennes—First, Mr. Jones, Royal

Gardens, Frogmore. Second, Mr. J. Miles, both having fine fruit.—One Pine of any variety—First, Mr. J. Tomkin, Peamore Gardens, near Exeter. Second, Mr. T. W. Bond, Weybridge, Surrey. Third, Mr. F. Rutland, who had a nice Prickly Cayenne.—Six Peaches—First, Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, Ledbury, with fine Noblesse. Second, Mr. J. Brown, gardener to Earl Howe, Gopsall, who had Royal George. Third, Mr. G. Sage, Ashridge Gardens, Berkhamstead.—Six Nectarines—First, Mr. J. Maher, Stoke Court, Slough, with Hunt's Tawney. Second, Mr. W. Gardiner, Stratford-on-Avon, with *Violette Hâtive*. Third, Mr. J. Stephenson, gardener to T. Barker, Esq., with *Imperatrice*.—Figs, one dish of twelve fruits—First, Mr. G. T. Miles, gardener to Lord Carrington, with fine well-ripened Brown Turkey. Second, Mr. W. Coleman. Third, Mr. J. Gray, Grange Park, Arlesford.—Fifty black Cherries of any variety—First, Mr. G. T. Miles, with Black Circassian. Second, Mr. T. Jones, Frogmore, with Black Tartarian.—Fifty white Cherries—First, Mr. Jones, with Early Biggarreau. Second, Mr. G. T. Miles, with Elton.—Strawberries, twenty-five fruit—First, Mr. D. Pizzey, Fulmer, near Slough, with fine fruit of Sir Charles Napier. Second, Mr. J. Douglas, Loxford Hall, with Sir Charles Napier. Third, Mr. George Sage, Ashridge Gardens, with President.—Twenty-five Strawberries of the British Queen or Dr. Hogg type—First, Mr. J. Douglas, with British Queen; the finest fruit shown. Second, Mr. G. Sage, with British Queen. Third, Mr. D. Pizzey, with Marguerite.—Grapes, three bunches, Black Hamburgs—First, Mr. J. Douglas, with magnificent and well-finished examples of good culture. Second, Mr. J. Johnson, gardener to the Marquis of Aylesbury, Savernake, Marlborough. Third, Mr. W. Bones, gardener to D. M'Intosh, Esq., Havering Park, Romford. Equal third, Mr. W. Coleman.—Three bunches of white Grapes—First, Mr. J. Douglas, with fine Canon Hall Muscat. Second, Mr. G. Parkhouse, gardener to T. Holman, Esq., Hawkhurst, with Bowood Muscat.—Three bunches of Frontignan Grapes—First, Mr. J. Douglas, Loxford, with fine well-ripened fruit. Mr. E. Clarke, gardener to Mrs. Hall, also had fair examples, to which a third prize was awarded.—Three bunches of Buckland's Sweetwater Grapes—First, Mr. W. Cole, Ealing Park, with three fine well-ripened bunches. Second, Mr. J. Douglas, with slightly smaller bunches; but well-coloured and perfectly ripened. Third, Mr. A. Johnson, with large clusters, not fully ripe.—Three bunches of Muscat of Alexandria Grapes (open)—First, Mr. Maher, who had fine clusters. Second, Mr. J. Douglas, with good bunches.—One green-fleshed Melon (open)—first, Mr. T. Jones, Frogmore, with Jobson's Hybrid Melon. Second, Mr. J. Douglas. Third, Mr. W. Coleman, with Gilbert's Victory of Bath.—Melons, scarlet-fleshed—First, Mr. D. Pizzey, with Scarlet Gem. Second, Mr. F. Bates, Appleby Hall, Atherstone, Scarlet-flesh. Third, Mr. J. Gray, Grange Park, Arlesford, with a fine highly netted fruit unnamed.—In the miscellaneous classes, a first prize was awarded to Mr. T. Jones, Frogmore, for a fine collection of Apples of marvellous firmness and colour for the season. Second, Mr. C. Ross, gardener to C. Eyer, Esq., Welford Park, Newbury; this last collection also included some fine examples of Uvedales St. Germain Pears, of large size and good colour; and Mr. G. Sage obtained an extra prize for a fine cluster of Bananas weighing 74 lbs., and quite as fine as the best imported specimens.

Vegetables.—For Messrs. Carter & Co.'s prizes for six dishes of Peas, including the following varieties—Carter's Extra Early, Premium Gem, McLean's Blue Peter, Carter's White Gem, and Carter's First Crop—there were two exhibitors. First, Mr. G. Pragnall, gardener to G. Digby, Esq., Castle Gardens, Sherborne, who had nice plump well-filled pods. Second, Mr. G. Brown, gardener to Edwin Mackenzie, Esq., Tawley Court, Henley-on-Thames.—Mr. G. T. Miles obtained an extra prize for a splendid box of Tomatoes. Some extra large Asparagus came from M. Lhèrault, of Argenteuil, near Paris. Some of the sticks of this were quite 2 inches in diameter, and about a foot in length.

First-class Certificates were awarded to the following:—

Vanda limbata (Williams).—This is a welcome addition to a well-known genus. In habit the plant is intermediate between *V. tricolor* and the old *V. Roxburghii*. The flowers are borne ten on a spike, and have long slender white peduncles, the sepals and petals being of a deep chocolate-brown, slightly netted, while the oblong blunt lip is of a lively rosy-lilac colour.

Double Zonal Pelargonium (Emila Laxton).—A free-growing plant which deserves to be grown for its vivid scarlet flowers, especially as they last so long after being cut.

Dendrobium amœnum (Bull).—This at first sight resembles a small-flowered *D. transparens*, but is quite distinct. The flowers are small, of a white colour, the segments tipped with rosy-lilac. The lip is tinged with yellow, and the flowers are deliciously perfumed like Violets. Though not showy it well deserves culture for its odour.

Macrozamia plumosa (Bull).—This is a fine decorative plant belonging to a well-known class of Cycads, invaluable for stove or warm conservatory culture.

Tacsonia insignis (Backhouse).—This is a fine climbing plant for a warm greenhouse, having dark-green heart-shaped leaves, woolly beneath, and great rosy-crimson flowers nearly 6 inches across. It is one of the finest of its class.

Gloxinia Queen of England (Lovell).—A large white variety marked with deep crimson in the throat.

Sarracenia Stevensii (Veitch).—This is a fine new hybrid raised by Mr. Stevens, at Trentham. It is the result of a cross between *S. purpurea* and *S. flava*, and in form resembles the last named kinds, with the deep red or purple markings of *S. purpurea*.

Clematis purpurea elegans (Cripps).—A bright violet-purple variety, of fine form, and well deserving of culture as a novel variety of a popular class of hardy or half-hardy decorative plants.

Pellæa sp. (Backhouse).—A dwarf-growing species, not yet determined, but none the less valuable as a garden plant.

Pellæa mucronata (Backhouse).—This, like the last, is from the Yosemite Valley. Its fronds are about a foot long, very much divided, and of a pale blue or glaucous tint. It appears from the robust plant sent, to be of free growth, and will, it is to be hoped, prove a useful addition to hardy Ferns.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE SPECTATOR ON GARDENERS.

A WRITER in the *Spectator*, in favouring the public with his own special views on the student's gardening and road-making at Hincksey, goes out of his way to fling a few ill-natured gibes at gardeners in general. The evidently self-satisfied writer deals with his subject after this fashion—"Gardeners," quoth he, "we sometimes fear, are just as little civilised as any other labourers." This sentence ought to have been indited without the assumption of the editorial "we." It exhibits such ignorance of the subject that the excellent journal in which it has been allowed to appear ought not to have been involved in the unripe opinions of a correspondent, by his assumption of that magniloquent "we." The writer in the *Spectator* ought to be informed that, in reference to gardening alone, there are both gardeners and garden labourers. The "gardener" of the present day, though he oftentimes uses the spade with his own hands, is a man carefully trained to his craft—a man who has been taught the nature of soils, the general effects of climate and temperature on vegetation, and not only the names, but the natures of many kinds of plants, which careful teaching and careful study have enabled him to store valuable knowledge to such good effect that he is always able and ready to impart, to such gentlemen as the correspondent of the *Spectator*, many items of information in a domain of science in which the greatest among us are continually interested. The "labourer" is the uneducated assistant of the gardener; he is to the gardener what the stone-breaker and the carter are to the road-maker. The great road-makers—the MacAdams and the Wades—are as unjustly stigmatised, when twitted by this learned critic as being "just as little civilised as other labourers," as the Paxtons, Kents, Browns, and Reptons are by that same flippant pen. This self-confident essayist goes on to inform his readers, that gardeners "get some vague notions of colour—about half as accurate as those of a Turkish weaver or Japanese potter, or a Cashmere shawl seller." It would be well, if possible, to make this writer understand, that the profession of a gardener has nothing whatever to do with that kind of appreciation of colour which is, or ought to be, required in textile fabrics, nor in that superficial knowledge of it which is useful to a seller of shawls; nor has he anything in common with the Japanese potter, who, as a rule, makes use of few harmonising tints, requiring, as he does, all the brightness of positive colours. The gardener, in his own domain, is a colour-student after a superior fashion to that followed by the potter or shawl weaver. By his knowledge of hybridising, the gardener has produced a whole paradise of new flowers of thousands of delicate gradations of hue, many of which tones and shades he has found the means of defining in words which often convey the idea of the new colour with felicitous accuracy. Let the rash writer of the article on the Hincksey experiment study a gardener's catalogue, say, of Roses only, and he will find accurate definitions of a hundred tones of rose-hues, described with a clearness that should alone convince him that the gardener is often an intelligent student of colour. Let him visit many of our gardens and he will find plants so well arranged, as regards colour, that he may even cease to think of the Japanese potter as his ideal artist in this respect. As regards the production, by the horticultural art, of new and beautiful flowering plants from parents that were originally little better than weeds, the writer in the *Spectator* twits the gardener by ejaculating, "He feels as if he had made the plants." And so he has! Nature is the mother of all; but, by the gardener's art, she has succeeded in producing beautiful results, which, but for his knowledge, his perseverance, and his skill of hand, might never have been born. Here and there, in long lapses of time, some honey-hunting insect carries the fertilising pollen from one flower to another

of congenial race, and seed may be produced from which a new and beautiful species may arise to embroider the wild carpet of Nature; but the result produced may be inferior to either parent, or a weakling that soon dies out and disappears for ever. The gardener, on the other hand, has reduced chances to laws; he produces hybrid plants almost at will, casting all worthless results aside, and carefully preserving the one, two, or three gems selected from thousands of his seedlings. The writer on Hincksey then proceeds to scatter broadcast accusations of "conceit." He takes, as his deepest incarnations of inveterate conceit, the "poet" and the "certificated schoolmaster," and proceeds to state that their conceit is far surpassed by that of a gardener "who has raised a new plant or done anything in the least noteworthy in the way of Orchids, or won a prize at the county flower show." In reply to this sweeping rhodomontade about conceit, one confesses at once not to have been aware, till so informed by this writer, that Homer, or Shakespeare, or Milton, or Tennyson, were to be accepted as typical examples of intense conceit; nor that our great certificated schoolmasters, Arnold and his compeers, were representatives of an intense kind of conceit which was yet surpassed by that of the "gardener." To those accusations against the gardener, intended by our "ready writer" to be so pitilessly crushing—namely, his raising of a new plant, his noteworthy success in the difficult culture of Orchids, and his winning a prize in open competition as an adept in his art—the natural reply appears to be that, to almost any other kind of mind than that of our ready writer, these achievements in an art "which does mend nature" would necessarily appear to be such as ought to awaken a just and honest pride in every enthusiastic gardener. If the gardener were an aristocrat in feeling, or cared much for the reflex of hereditary honour, he might claim to be a living representative of the most ancient and important craft in the world—the craft that has transformed the land of a great part of our planet from a waste to an earthly paradise—a craft honourable and useful, which brought to perfection many kinds of esculents, sweet and good for the nourishment of man, ages before the calling of the newspaper correspondent was heard of, or even the art of writing invented. In taking leave of the worthy essayist, on the intolerable conceit of poets, schoolmasters, and gardeners, may one of the delving craft be allowed to inform him that we, the delvers, have always thought that the caterers for the press are not sufficiently honoured in our country, and that while we are justly proud that Charles Lawson, the gardener, was twice Lord Provost of Edinburgh, and that the great palace of glass won for the gardener Paxton a world-wide fame and a title which, though no worshippers of titles, we honour in that of the late Sir Joseph Paxton, we, nevertheless, sincerely regret that a similar share of honour has not fallen to the equally hard-working labourers of the press.

A GARDENER.

WE have received a number of letters with reference to the note on "Gardeners and the Hincksey Diggings," quoted in our last issue, with the general tenor of which we heartily agree. With reference to "conceit," it is pointed out that even if some of the younger and less-experienced of the craft do manifest a little of this quality, there is surely a vast difference between being "conceited," in consequence of originating a new, and it may be most valuable or ornamental plant or fruit tree, and exulting because of excellence in coarse or brutal pursuits. We know some gardeners who have benefited the country at large by their productions, and who are in no sense more conceited than men of any other class. Pure conceit is impossible with a man of high intelligence, but all such men must have a consciousness of their own power, and, it may be, take a harmless pride in their work. Conceit is common enough in all classes among young and untravelled persons, and many young gardeners have had no opportunity of seeing anything but what is found in their immediate neighbourhood. Our own opinion is, that the "*Spectator*," and also some recent novelists, do scant justice to gardeners, the truth being that they are generally the most intelligent men in their rank in life, and frequently remarkable for great knowledge and skill. They can afford, therefore, to disregard the sneers of the novelists, who usually know nothing about them. Besides, the Rev. Mr. Hole, himself a gardener, has painted the gardener as he is, and the "*Six of Spades*" contains the truest sketches of the gardeners of our own time ever written.

NOTES OF THE WEEK.

— VARIOUS correspondents write to us about the size of the Iris figured in last week's GARDEN, supposing that our proportions were wrongly given. This was not the case; the flower sent to our office by Mr. Connell, the gardener at Stonehouse, was more than 9 inches in diameter.

— BY far the handsomest *Coleus* leaves we have seen are some just received from Mr. Cannell, of Woolwich. They have deep brilliant and delicate colours, one side of the leaf being laced or edged with green, the other with yellow, and one half of the leaf in some instances is a deep claret, the other rosy-crimson, while some of the younger leaves are wholly carmine.

— THE graceful and curious *Aphyllanthes monspeliensis*, familiar to those who have gathered plants on the Maritime Alps, is quite hardy in the neighbourhood of London. There is a tuft of it in the Botanic Gardens, Regent's Park, much stronger than we have ever seen in its native country; the fine grass-like tuft is studded over with blue flowers, which appear in succession.

— THE Rev. Harpur Crewe sends us some blooms of the new hardy *Geranium arenarium*, it is one of the best perennials yet introduced. We first saw it in M. Boissier's garden near Lausanne, and it was first grown in England by Messrs. Backhouse, of York, who, we believe, sent out plants of it under the name of the old, and not rare, *G. Lambertianum*. M. Regel named it *G. Backhousianum*, not knowing that it had been previously described.

— WE hear from a correspondent at Lincoln, Nebraska, that fruit prospects in that country are excellent this year. In the counties along the right bank of the Missouri, fruit trees are said never to have been in fuller bloom than at present. Apples, Pears, Plums, Cherries, and Peaches, promise an abundant crop. These river-side counties, at present, are those in which most of the fruit of Nebraska is grown. The inland parts of the State, however, are beginning to dispute this special pre-eminence of the eastern counties. The soil is well adapted for fruit, and orchards and vineyards are being planted everywhere.

— Two handsome blue-flowered species of *Pentstemons*, named respectively *P. glaucus* and *P. heterophyllus*, are now in flower on the rock-work at Kew. The blooms of the first, though small, are produced in tolerable abundance, while those of the latter, a very distinct foliage kind, are about the same size as those of *P. crassifolius*. Both these species are deserving of a place in all good collections. Among other plants, now in flower at this spot, is a fine specimen of *Saxifraga Cotyledon*, with a pyramidal spike, about 18 inches high, thickly studded with pretty white flowers. *Saxifraga Willkommiana*, a kind somewhat resembling *S. granulata*, is also in bloom, as is likewise *Lotus Salzmanni*, a silvery-leaved species, with large clear yellow flowers.

— IN a recent report of the United States Commissioner of Agriculture, it is stated that the wild Potato plant was growing in great abundance in that portion of Northern New Mexico lying between Fort Wingate and Fort Defiance. The Navajo Indians inhabit this section, and the native Potato forms one of their chief articles of diet in winter. The women dig the root with whatever implements they can get, often using a strong smooth piece of wood with a wedge-shaped end. The plant grows on low rich spots, and by spring the earth is torn up in every conceivable direction, in the search for Potatoes. The tubers are quite small, one-half to three-quarters of an inch in diameter, of good taste, and somewhat like boiled Chestnuts.

— MR. E. J. LOWE, of Highfield House, Notts, has stated in reference to the leafing of the Oak and the Ash, that during the past thirty years in no instance has the Ash been in leaf before the Oak. It must be mentioned that certain individual trees were selected as subjects of observation inasmuch as some Oaks will be very late and some Ash trees will be much earlier than others, and *vice versa*. It is quite possible to find certain individual Ash trees in leaf before certain individual Oaks, yet this is owing in most part to geological condition. Trees on the Bunter are in leaf (as a rule) earlier than those on the Keuper formation, and as the great North fault, as it is called (of about 100 yards), passes across my estate I have peculiar opportunities of studying the effect produced. Trees growing so near to each other as to have their branches mingled together will nevertheless have their roots growing in distinct strata, geologically the one being 100 yards higher than the other, causing one of the trees to be leafless until after the other has become fully in leaf. The Ash is but a few days later than the Oak, and the range in thirty years in coming into leaf is also limited (at this time of the year) to a few days, while the range of the common *Ribes* coming into flower (some three months earlier) is nearly fifty days. The Beech, which usually comes into leaf on the 28th of April, was this year in leaf on the 25th

of April (the range being from the 24th of April to the 6th of May), but the subsequent cold weather so retarded vegetation that the Oak was later by three days than usual.

— A CORRESPONDENT sends us a short distorted Cucumber, which he says pushed up from the root, but does not send the root showing the connection between the two! Have any of our readers witnessed a similar case?

— ALTHOUGH the season has been unfavourable for Irises, they are blooming beautifully just now in various establishments round London. At one or two places the flowers of *Sparaxis* and *Ixias*, from bulbs planted out in early spring, are also conspicuous.

— ACCORDING to the *San Francisco Bulletin* there have now been planted in California probably not less than a million trees of the *Eucalyptus globulus*, or blue Gum tree, which is so famous for draining damp soils and destroying malaria.

— MR. MARK FIRTH, who recently built and endowed a block of almshouses in Sheffield, at a cost of upwards of £40,000, last week purchased the Page Hall estate, situate near Sheffield, for £25,550. It is Mr. Firth's intention to set apart a portion of the estate as a public park and present it to the town of Sheffield.

— THAT botanically very interesting and rather imposing hardy plant, *Megacarpæa polyandra*, is in flower just now both at the College Botanic Garden and Glasnevin. A Polyandrous cruciferous plant is a singular anomaly, and, as such, *Megacarpæa* has a special interest for the systematist and botanical student.

— ALL interested in fine-foliaged hardy plants should, when visiting Kew, make a point of seeing a plant of *Polygonum sachalinense* in the herbaceous grounds near the museum. This vigorous and handsome plant is just now a very imposing object, 7 or 8 feet high, clothed with large bright green foliage, in which there is a graceful tendency to droop.

— THE lady visitors to the Jardin d'Acclimatation do much injury to the flower-beds by gathering and carrying off the choicest specimens. The following graceful appeal has been suggested for use in consequence:—"Les fleurs qui ont des crinolines sont priées de faire grâce à celles qui n'en ont pas." Is it possible to veil an order more delicately?

— THE tallest of the many kinds of Iris now in flower is *Iris ochroleuca*. It is one of the species that will grow freely on the margin of water, like our common Flag (*I. pseud-acorus*); and is, therefore, worthy of the attention of those who take an interest in water-plants. It may be seen both at Kew and the Botanic Gardens in the Regent's Park.

— ALTHOUGH the *Spergula* is admitted to be unfitted for the purpose of forming a good turf by itself (no one kind of plant ever can form a perfect turf), its value as a component part of lawn-turf does not seem to be well known. In Mr. Mongredien's garden, at Forest Hill, there are little patches of *Spergula* here and there in the lawn, the effect of which is very good indeed.

— THERE is now about to flower in Mr. Mongredien's interesting garden at Forest Hill, an Australian plant, usually supposed to be tender—*Lomatia longifolia*. It is planted out in a *Rhododendron* bed, and has lived through the winters of the past eighteen years, being cut to the ground twice during that period; it sometimes ripens fruit. A *Camellia* has stood twenty years as a bush on the lawn of the same garden.

— THERE is a harrowing description of a "man-eating plant" going the rounds of the papers. It is said to be a native of Madagascar, and to trap men and women as the *Dionæa* does flies. We quote one of the least sensational paragraphs of this "strange story." "The retracted leaves of the great tree kept their upright position during ten days; then when I came again one morning, they were prone again, the tendrils stretched, and nothing but a white skull at the foot of the tree. The indescribable rapidity and energy of its movements may be inferred from the fact that I saw a smaller one seize, capture and destroy, an active little lemur, which, dropping by accident upon it while watching and grinning at me, in vain endeavoured to escape from the fatal toils."

— MR. ALBERT GRANT is resolved to tread still further in the path of popularity opened up by him in his gift of Leicester Square to the public. He has, according to the London correspondent of the *Scotsman*, had an interview with the Prince of Wales, to obtain His Royal Highness's countenance to the project of purchasing, decorating, and throwing open to the public all the square gardens—eighty-four in number—in the metropolis. He believes that by so doing he will not only make these gardens—in many cases languishing—more healthy and more ornamental, but by allowing the public to traverse them, increase the facilities for that open-air exercise which the Londoner has in many cases but little opportunity of indulging in.

THE FLOWER GARDEN.

CULTIVATED GENTIANS.

At this season, when the mountain pastures of Europe are dyed with the unrivalled blue of the Vernal, the Bavarian, and other Gentians, we may appropriately call attention to the various cultivated species, so little seen in gardens generally. *G. acaulis* has here and there escaped extermination in old gardens, and is, indeed, beginning to be duly esteemed in many of the new; but many of the rarer species are as yet too frequently confined to botanic gardens or choice collections. Of this very extensive genus, De Candolle has described, in his "Prodromus," no fewer than 153 species. These are very widely distributed, a large proportion of the number being indigenous to the tropical regions of South America, especially in the Peruvian Andes, while others are natives of Mexico and other parts of N. America, Kamtschatka, Tierra del Fuego, the Falkland Islands, Patagonia, the Himalayas, Ceylon, Van Diemen's Land, Siberia, and various localities in the Alpine districts of Europe. Five species are natives of Britain. Of all these, at present, there are not more than some two dozen species in cultivation, and only a few of these are generally to be met with in gardens. All, however, are well worthy of culture, for the sake of the great variety which they present, and the rare beauty of many of the species. In the hope of directing more particular attention to these plants, we have drawn up the following descriptions of the best kinds grown by our nurserymen, including the British species.

***Gentiana acaulis* (Gentianella).**—This is one of the finest and most commonly-grown species, forming dense carpets, 2 or 3 inches high, of ovate-lance-shaped leathery shining leaves, which, in the summer time, are covered with a profusion of large, erect, bell-shaped flowers, often 2 inches long, of a brilliant ultra-marine or sapphire colour, and continuing in bloom for a long time. It grows well in a deep moist loam, and is an excellent subject for the rock-garden, borders, or edgings. A few years since M. Anjubault of Mans, stated, in the *Revue Horticole*, that he obtained the finest flowers by putting his plants in a spent hot-bed exposed to the sun, watering them frequently, and cutting away superfluous shoots. *G. alpina* is a variety of this species, with shorter and broader leaves, and flowers half the size of those of *G. acaulis*, and usually of a lighter blue. *G. excisa* also very closely resembles this species. Native of the Alps and Pyrenees. Propagated by division of the tufts or from seed. Grows well in rich gravelly loam.

***G. asclepiadea*.**—A tall handsome plant, with simple, Willow-like, erect stems, swollen at the joints, growing from 15 inches to 2 feet high, and bearing numerous flowers on a considerable portion of their length. The flowers, which appear in summer, are rather large, bell-shaped, of a deep purplish hue, with dark dots inside, and are borne in pairs, numerous, axillary, and nearly sessile, forming spikes of considerable size. The leaves are ovate-lance-shaped, sessile, about 2 inches long and $\frac{3}{4}$ inch broad at the base. Native of the mountains of Central and Southern Europe and the Caucasus. A good plant for borders or the margins of shrubberies, in almost any soil, but thrives best in a rich, fibrous, deep, and moist sandy loam. There is also a variety with white flowers.

***G. bavarica*.**—This beautiful species very much resembles the British *G. verna* in its habit, size, and flowers, but is somewhat taller and has blunter and smaller Box-like leaves, suffused with a yellowish tint. It grows in dense tufts about 3 inches high. The flowers, which appear in summer, are large, and of a most exquisite, brilliant, velvety, and intensely deep Prussian blue, sometimes tinted with purplish-crimson. For beauty of colour, the flowers of this species bear the palm above all others. Native of Alpine meadows in

Central and Southern Europe. The author of "Alpine Flowers" informs us that he found this plant growing in spongy places, in which the foot sank to the ankle in water at every step, but our own experience has taught us that, in cultivation, these conditions are absolutely fatal to it, and we have seen it in its highest perfection on the unrivalled rockery of Mr. James Backhouse, at York, growing in a compost of peaty loam and grit, with no greater amount of moisture than is dispensed to the surrounding plants. Multiplied by division of the tufts, or from seed, if it can be ripened.

***G. Burseri*.**—A very rare tallish species, growing from 1 to 1½ feet high, with dense heads of yellow flowers, which are sometimes spotted with purple; corolla, with six divisions; divisions of the corona, triangular; leaves, oblong-elliptical, the upper ones acuminate or pointed. Native of the Eastern and Central Pyrenees. Grows well in rich, fibrous, gravelly loam. A variety of this species, named *Villarsii*, found in the Provençal Alps, has the divisions of the corona truncate, and the flowers dotted with purple.

***G. cruciata*.**—This species has somewhat erect spreading leaves, arranged at right angles, or cross-like, on simple ascending stems, which are from 6 inches to 1 foot in height. The flowers are axillary and terminal, blue, and produced in whorls, which have a capitate or head-shaped appearance. Native of dry pastures in Central and Southern Europe and Siberia. It has a four-angled creeping root, or rhizome, split into connate bundles of four, and fibrous or hairy at the top. In growing this plant, the fibrous loam should be plentifully mixed with small pieces of broken limestone.

***G. gelida*.**—A vigorous-growing species, forming dense tufts or carpets a foot high, with bent ascending stems, and ovate lance-shaped blunt leaves, closely set. Flowers very fine, nearly two inches long, in very large heads of a brilliant blue colour. Native of Alpine districts in the Caucasus and Armenia. Grows well in rich moist loam, and is multiplied by division, or from seed, which it produces abundantly.

***G. imbricata*.**—This species is distinguished by the densely overlapping elliptical-acute leaves which cover the stems of the plants. It grows from 6 to 8 inches high, and bears short-tubed flowers of an azure-blue colour. Native of the Swiss Alps, Carniola, Carinthia, and the Southern Tyrol. In cultivation, this plant requires an admixture of rich loam with small pieces of broken limestone.

***G. lutea*.**—This is the largest species of the genus, and sends up stout stems 3 to 4 feet, or more, in height. Placing it side by side, with *G. verna*, *G. acaulis*, or any of the dwarfer species, few would believe that it belongs to the same family. It possesses none of the concentrated beauty of the species hitherto described, but is, nevertheless, a striking plant, well adapted for the back part of borders or the margins of shrubberies, and might be effectively introduced into groups of such plants as *Nicotianas*, *Wigandias*, &c. The flowers, which are of a pleasing yellow, are of a large size, and are produced in axillary, umbel-like, whorled cymes, on the upper part of the stem. The leaves are very large, ovate-oblong or ovate-acute, and grow in opposite pairs. Native of the Alps of Central and Southern Europe. In cultivation it is very indifferent as to soil, but grows best in a rich deep loam. This plant, independent of its horticultural uses, possesses no inconsiderable value in an œconomic point of view, as it furnishes the "Gentian-root" of commerce, so highly esteemed in the tonic preparations of the chemist.

***G. Andrewsii*.**—A very singular species, with erect smooth stems about a foot high, bearing terminal clusters of inflated purplish-blue flowers, each an inch long. These flowers never expand, as the lobes or divisions of the corolla are united at the edges, so that the flowers have the appearance of small cones. Leaves, ovate lance-shaped, pointed, rough on the margins. Native of North America, from Carolina to Lake Huron. Grows well in rich moist soil, and is multiplied by division of the tufts.

***G. angustifolia*.**—A rare and beautiful species, with erect, slender stems, from 6 to 15 inches high, each bearing a single, large, terminal, azure-blue flower, 1½ inch in length, and of a narrow ob-

Gentiana verna (natural size).

conical shape, spreading at the mouth. Leaves, linear, obtuse, smooth at the edges. Native of North America, from Carolina to Canada. It should be grown in moist and very sandy loam and peat, in rather shady situations.

G. ciliata.—Another rare and beautiful species, with flexuose, almost simple, stems about 1 foot high, bearing large, solitary, azure-blue, deeply fringed flowers, from 1 to 1½ inches long. Leaves, linear, obtuse, roughish at the edges. Native of the Alpine regions of Central and Southern Europe, and the Caucasus, in dry pastures. It requires to be planted in a mixture of rich fibrous loam and broken limestone, in sunny fissures of rock-work; or may be grown in well-drained pots, using the same compost. In all cases, it should be kept rather dry in winter. Young plants flower freely when only 2 or 3 inches high.

G. crinita.—A handsome biennial species, with an erect stem, branching in the upper part, and from 1 to 2 feet high. It blooms late in autumn, bearing large blue-fringed flowers nearly 1½ inches long. Leaves, lance-shaped, heart-shaped at the base, pointed at the apex, and roughish at the edges. Native of North America, from Carolina to Canada, in moist pastures and woods. It should be grown in rich moist loam, either on rock-work, or in pots, or borders.

G. frigida.—An exceedingly pretty dwarf species, with erect slender stems, 2 or 3 inches high, bearing usually a single erect large terminal flower, of a creamy-white colour, marked with a few purplish dots. Leaves, linear-spathulate or spoon-shaped, obtuse, and smooth at the edges. Native of the Alps of Upper Styria, and the Carpathian Mountains. A Siberian variety, *G. algida*, has solitary flowers, each 2 inches long. It should be grown in a mixture of rich loam and broken limestone.

G. punctata.—A robust erect-growing species, with stems from 1 to 2 feet high, bearing terminal clusters of large yellow flowers, irregularly spotted with purple; each flower 1¼ inches long. Leaves, elliptical, shortly pointed, five-nerved, smooth at the edges. Native of the Alps of Southern Europe, and the Carpathian Mountains. Soil, &c., as for the preceding species.

G. purpurea.—A vigorous-growing species, with purplish-green stems from 1 to 1½ feet high, bearing from three to eight terminal flowers in a whorl, in addition to several solitary axillary ones. Flowers, large, purplish, marked with dots in lines inside; tube striated with greenish-yellow. Root-leaves, ovate, five-nerved; stem-leaves, broadly lance-shaped. Native of the Alpine regions of Central and Northern Europe. Suited for borders in rich sandy or gravelly loam.

G. pyrenaica.—A very distinct and beautiful dwarf species, with short tufted stems, about 3 inches high, blooming in summer, and bearing large solitary brilliant purple flowers, pale green on the outside, each 1 inch in length. Leaves, imbricated, linear-lance-shaped, pointed, rough and cartilaginous at the edges. Native of the Pyrenees, Hungary, and the eastern parts of the Caucasus. This species has somewhat of the appearance of *G. verna*, but is of freer growth. It does well in rich sandy or gritty loam.

G. septemfida.—A curious species, with erect simple stems, 6 to 12 inches high, blooming early in summer, and bearing clusters of cylindrical flowers, of a blue and white colour inside, and greenish-brown on the outside, and having, between each of the larger roundish segments, a smaller one finely cut. Leaves, ovate lance-shaped, three-nerved, decussate, crowded. Native of the Caucasus. Suitable for rock-work or choice borders, in fine sandy loam.

British Species.

G. verna.—One of the most charming plants of the genus, forming dense tufts, 1 to 3 inches high, which, in spring, are covered with a profusion of large brilliant blue flowers, each an inch or more across, and frequently showing a white centre. Leaves, ovate, somewhat acute, those of the root crowded; stem-leaves in about three pairs. Native of a few localities in Northern England and Western Ireland, but very abundant on the Alps of Central and Southern Europe. It is an excellent subject for the rock-garden, choice borders or for pots. Mr. James Backhouse, of York, who grows all the cultivated species of *Gentian* to perfection, has given the following valuable directions for the culture of *G. verna*:—"It grows freely on very choice sunny banks, in deep, rich, fibrous loam, mingled with pieces of limestone, gravel, and a little 'cocoa refuse.' Rapid drainage, and as rapid and constant a supply of percolating moisture are essential to full vigour. It grows freely in pots, in the above-named mixture, if kept moist all summer, or in an ordinary garden border, in loam mingled with gravel."

G. Pneumonanthe.—A handsome sub-aquatic species, growing in marshes and on moist heaths and pastures, with erect stems, 6 to 12 inches high. The flowers, which appear late in summer and in autumn, are large, 1½ inches long, or more, of a deep blue colour within, with five greenish dotted belts on the outside, and are

produced in opposite pairs in the axils of the upper leaves, with a terminal one between the last pair. There is a variety with white flowers. Leaves, smooth, upper ones nearly linear, lower ones oblong lance-shaped, all obtuse and rather thick. Native of England, various parts of Europe, and Siberia. The proper place for this plant is in the artificial bog, but it may be also grown on rock-work or in the choice border, if planted in deep and very moist soil.

G. Amarella.—An annual species, flowering in the end of summer and in autumn, with erect, slender, and much-branched stems, from 3 to 4 inches to nearly a foot high. The flowers are numerous, of a pale purplish-blue colour, and are sometimes disposed in a loose, oblong, leafy panicle. Lower leaves, oval, spoon-shaped, upper ones ovate lance-shaped. Native of most parts of Britain. This plant grows well in rich sandy loam, in an exposed sunny position.

G. campestris.—Another annual species, much resembling the last, but is usually rather stouter, more branched, and more crowded with leaves and flowers. It seldom grows more than 6 inches high. The flowers, which appear in the autumn, are of a violet-blue colour, and the mouth, which is divided into four segments, is margined with a very conspicuous blue fringe. Leaves, elliptical-oblong, somewhat pointed. Native of Britain, and more common than the last-named species. Easily grown in ordinary garden soil.

G. nivalis.—This is also an annual species of very dwarf dimensions, with slender, erect, leafy stems often only 1 inch (but more frequently 2 to 4 inches) high, and more or less branched, each branch bearing a single blue flower, much like that of *G. verna*, but considerably smaller. Leaves, ovate, pointed, roughish at the edges, the lower ones more frequently obovate and disposed in rosettes. Native of Britain, but only found on the higher Scotch mountains; common on the mountain ranges of Central and Northern Europe. It grows best in a mixture of rich loam and broken limestone.

The preceding enumeration comprises all the best species of *Gentian* at present in cultivation. The culture of most of them presents no very great difficulty, although in a few cases, perhaps, beginners may meet with disappointments. A little attention, however, to the requirements of the plants as to soil, position, the suitable degree of moisture, &c., is sure to be repaid by satisfactory and successful results.

W. M.

VIOLETS.

In order to have Violets from November to June, now is the time to make preparations. The Violet is propagated exactly like the Strawberry, and, like that plant, it flowers well according to the vigour of the stools, this vigour depending upon the planting of early offsets or runners, and their treatment during the summer. Everyone who has a garden and a two or a three-light wooden frame may have Violets throughout winter and spring. We have been gathering bunches, two or three times a week, of the Neapolitan chiefly, and there are none better from November to June, from a three-light frame. I will describe the frame culture first. Here we have a frame for the purpose, in which the plants are both grown and flowered, it being heated with a 2-inch lead pipe in connection with another house. In such a frame, of course, no hot-bed is necessary, as the little heat required during cold weather in winter can be supplied by the lead pipes. In many places, however, the frame will be required during summer for other purposes, and the Violets must then be grown on a shady border and transferred to the frame in September. Whichever plan may be adopted, the summer culture is the same, and consists in securing good runners early in summer by pegging down the offsets at a joint and pinching them beyond that, and, when rooted, transplanting them to the bed or frame, as the case may be. Some never take the trouble to layer young plants, but simply divide the old stools into single crowns, and plant them in the frame or bed at once. This is the quickest and most convenient plan; but young plants from offsets produce the finest flowers. During summer, the plants must have abundance of water, and, if they are not in a naturally shaded situation, they should be shaded in dry sunny weather and syringed often. By September they will be nice stocky plants; and, if they have been grown in the open border, they must then be transferred to their winter quarters. If a heated frame cannot be spared for them, a hot-bed, consisting of spent fermenting materials, should be prepared, and on this the frame should be set. Six or 8 inches of nice light rich soil should be put in, and the

Violets planted as closely together as they will bear without crowding. The more plants the more flowers. Care must be taken to lift the plants with good balls, and above all, it must be seen that the heat of the bed is not above 65° or thereabouts. A permanent but very gentle heat is what is required; therefore avoid making the bed of rank materials. In fact, an old spring hot-bed that has stood all summer is generally the best place for a Violet frame in winter, or an old spent hot-bed turned over again, and squared up for the the purpose will do. All that is required is just sufficient heat to keep the Violets growing and flowering gently all the winter; and any slight stimulus will do this, with the assistance of linings round the frames and mats at night in cold and frosty weather. The frame should have a rather sharp slope to the south, so as to receive as much sunshine as possible during the winter months. Nothing like forcing should be attempted to get the plants into flower early. A mild greenhouse temperature, with gentle dewings in bright afternoons, and a little ventilation always, is all that is needful to bring well-grown plants into flower by the middle of October. The less the plants are pushed the longer they will continue to flower. As regards varieties, I know none to surpass, and few to match, the Neapolitan for scent and a profuse flowering habit, especially for early blossoming. There are beautiful double varieties now well worthy of cultivation; but they do not open their flowers freely during the winter, and, consequently, have little scent. The Czar is a good useful kind, well scented, and with long flower-stems, which make it useful for bouquets. Plenty of it should be grown out-of-doors, in clumps of a convenient size, for transferring to 7 or 8-inch pots in autumn, and forcing in the conservatory or any other house with a genial temperature. Presuming that the frame and pot plants, which I shall refer to shortly, have kept up the supply of flowers till late in spring, a succession must be looked forward to from the outdoor stock. These should consist of the Czar, Common Russian, and any other single and double varieties that are found to succeed; and they should be planted in south, north, east, and west aspects, in shady places, and, in fact, anywhere where they will grow. This will ensure an abundant supply of flowers till late in the season with very little trouble. The Violet will grow in almost any soil, but it shows a curious partiality to some soils and localities. It delights in a somewhat rich light soil, yet it must not be too light; too much leaf-mould, for instance, it does not care for. A compost in which the staple is a stout friable loam suits it best. Very heavy soil is not unsuitable, but it should be lightened with leaf-mould and sand. In light soils well-rotted cow manure is an excellent stimulant. It is advantageous to have plants also in pots, as they can be used for house decoration effectively; and a few pots set about the conservatory always gives an agreeable perfume to the house. Pot plants are propagated in the same way as the others. The young plants are potted about the end of May or beginning of June, or even later, in 4½-inch and 5-inch pots, and plunged in the border during the summer, and watered and kept clean till October, when they should be stowed away in a cold frame, and either plunged in ashes or set closely together, as a protection to the roots from frost or drought. From the frame they may be taken in batches, as wanted, and pushed into flower in a warm greenhouse or pit, always keeping them near the glass, and where they can have the benefit of the ventilation. The insects which trouble the Violet most are green fly and red spider. The first is generally the result of a close unhealthy atmosphere, and is most easily got rid of by gentle smokings. Red spider is caused by strong sun and by dryness at the roots; hand-dusting with sulphur is the best remedy; but it is easy to prevent its occurrence by maintaining a damp atmosphere by syringing the house.

J. S. W.

IRISES.

I HAVE never seen the magnificent species of Iris, figured in your last number (*I. susiana*), flower out of doors except in very light sandy soil, though, I believe, it grows naturally in a strong loam, and it is quite rare to see it living in a border at all. Mr. Atkins, of Painswick, grows it well in pots, but it is

by no means an easy plant to flower; and, as for standing forcing, as I have seen stated by old writers, I do not believe it possible. I should much like to know how the *Iris iberica* and others of the same section (*Onocylus*) can be grown in this country, as they seem to be almost universally failures. I am going to try them this year in a frame planted in strong soil, which they certainly will not live in out of doors in my garden, and roast them in the summer as much as possible. This will come nearer their natural condition of life as far as I can learn. While on the subject of Irises, I want to know whether any of the following species are, or have been, in cultivation in England, as I should much like to get them:—

Iris caurina, from Canada, near Virginica, but distinguished by its simple flower-stalk.

I. Hartwegi, from California, where it grows on the Sacramento Mountains. Resembles *I. tenax*.

I. Tolmiana, a Californian form of *I. sibirica*; possibly the same as the Japanese one. I lately saw a very fine variety of this species at Bitton, with crimson bracts, from Japan.

I. decora (Wallich).—Himalayas; same as *nepalensis* of Don, not *nepalensis* of Wallich, which is only a variety of *I. germanica*, I believe.

I. kumiaonensis (Wall.), *longifolia* (Royle), figured in illustrations of Himalayan plants. A fine species.

I. sulcata, *fasciculata* of Jacquemont. Himalayas.

I. aurea (Lind.).—Cashmere; a fine golden-flowered plant, possibly a variety of *I. sambucina*.

I. gracilipes (A. Gray).—From Japan; a small delicate plant.

I. Tigridia (Bunge).—Altai Mountains.

I. paradoxa (Steven).—A splendid species from Eastern Caucasia, figured in Regel's "Garten Flora." Belongs to the same group as *iberica*.

I. sicula (Todare).—From Sicily.

Xiphion palestinum.—Grows on Mount Tabor, Hermon, and other places in Syria. A very fine species.

X. Histrio (Boiss.).—Lebanon. Near *Iris reticulata*. [This flowered on a border, with an east aspect, at Kew last January.—Ed.]

X. Aucheri.—Syria and near Aleppo. A curious species, near *scorpioides*.

Any information about these, or any other rare species of this beautiful and much-neglected genus, the synonymy of which is in most awful confusion, will be very gladly received by me.

W. J. ELWES.

THE IVY-LEAVED TOAD FLAX.

(LINARIA CYMBALARIA.)

I FIND this elegant little plant exceedingly useful for decorative purposes. Though originally a native of Italy it is now very general in England, and will thrive in the most exposed places on old walls and crumbling ruins. I first met with it in the Island of Anglesea, North Wales, where it almost covered a low wall facing the sea, for very nearly a quarter of a mile, where it was occasionally washed by the salt spray in winter, and as I never since saw finer specimens of this "Wandering Jew" (that being its local name in North Wales), I conclude marine air agrees best with it. I was making a rough kind of rockery at the time, and rather at a loss for plants in such a wild, "out of the way," sort of place as this is; my rockery, too, was to stand on a lawn, where very few shrubs or flowers would grow in consequence of its being so near the sea; therefore, I was perfectly charmed to meet with this pretty Toad Flax, and, carrying off a large basketful of it, I placed it in nooks between the Ferns, and likewise on a piece of rock-work I had especially devoted to sea-shore plants. Both places seemed to suit it equally well, and its change of quarters did not effect it at all. By June, its lovely mauve flowers, and graceful leaves had covered nearly all the stones I wished to hide, and in the autumn I removed a large patch of Moss, entirely covered with *Linaria*, from off the walls of Penmaen Priory, and put it in a hanging basket in my sitting room. It grew beautifully, and came into bloom much earlier than the out-of-door plants did. It climbed the sides of the basket, and its beautiful tendrils hung down covered with blossom. Everyone admired it, and would scarcely believe it was only a "common weed," as some people term all wild flowers. The yellow Toad Flax is a showy plant, but very unlike the Ivy-leaved. I removed some of it, together with Foxglove, into my garden, and their bloom contrasted well during the month of July, backed by a low Privet hedge, but the Foxglove faded away, long before the "Butter and Eggs," as it is called, disappeared.

Berry Grove, Liss, Hants.

H. E. W.

THE GENUS TRITOMA.

THIS important genus comprises fourteen species, all of which have been well described by Mr. J. G. Baker, in the *Journal of the Linnean Society*, of whose annotations on these striking autumn-flowering plants we translate an abstract. At the present time, scarcely half-a-dozen species belonging to this genus are in cultivation. It would be difficult to overrate the value of Tritomas as late-flowering plants. They are called Kniphofia by Mr. Baker; but, as they are more popularly known as Tritomas, we prefer to give them that title.

Tritoma (Kniphofia) Uvaria.—This is the most showy and commonly grown species, growing from 3 to 4 feet high, or more, and producing a dense spike of flowers, which is often more than 6 inches long. The flowers are tubular, about $\frac{1}{2}$ inch long, and are, at first, of a brilliant scarlet, but ultimately fade into yellow, so that the flower-spike presents, at the same time, a crown of flowers, the upper ones of which are of scarlet, while the lower ones are of an equally fine yellow. The leaves are all radical, from 2 to 3 feet long, and 3 or 4 inches broad. This plant, and, in fact, all the species, grow well in ordinary good garden soil, but thrive best in rich loam or peat and sand. They are all easily multiplied by division of the plants in autumn, taking care to preserve with each division a portion of the fibrous roots. Begins to flower in September.*

T. Rooperi.—A very dwarf species, the flower-stem being less than a foot high. Flower-spike, 3 to 4 inches long, and about 3 inches broad. The flowers in the upper half of the spike are scarlet, while the fading ones in the lower half are of a delicate yellow, affording a pleasing contrast. Native of Caffraria. It flowers later than *T. Uvaria*.

T. Burchellii.—This species grows from 2 to 3 feet high, and bears a rather loose flower-spike, 3 or 4 inches long. Leaves, 2 to 3 feet long. Flowers, from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches long, of the same colour as those of *T. Uvaria*, and which is the prevailing colour of the genus. Native of the Cape of Good Hope.

T. parviflora.—Flower-spike, 3 inches long. Flowers, scarcely $\frac{1}{2}$ inch long. Leaves, linear, about 1.6th inch broad. Cape of Good Hope.

T. breviflora.—Flower-stem, 9 to 12 inches high. Flower-spike, 1 to $1\frac{1}{2}$ inches long, and about 1 inch broad. Flowers, all yellow. Leaves, 9 to 12 inches long. Cape of Good Hope.

T. gracilis.—Flower-stem, 2 feet high. Flower-spike, $2\frac{1}{2}$ to 3 inches long, and 1 to $1\frac{1}{4}$ inches broad. Flowers, whitish. Leaves, 2 feet long, 1.6th inch broad. Native of Natal.

T. triangularis.—Flower-stem, less than a foot high. Flower-spike, $1\frac{1}{2}$ to 2 inches long, scarcely $\frac{1}{2}$ an inch broad. Leaves, triquetrous in the upper part, 10 or 11 inches long, linear, about 1.12th inch broad. Cape of Good Hope.

T. Abyssinica.—Flower-stem, 9 to 12 inches high. Flower-spike, 1 or 2 inches long. Leaves, 9 to 12 inches long, linear, about 1.12th inch broad. Native of Abyssinia.

T. sarmentosa (media).—Flower-stem, from 1 to $1\frac{1}{2}$ feet high, or more. Flower-spike, 2 to 4 inches long, and 2 inches in diameter. Leaves, glaucous, smooth, 12 to 18 inches long, and about $\frac{1}{2}$ an inch broad. Native of the Cape of Good Hope.

T. isoetifolia.—Flower-stem, 16 to 18 inches high. Flower-spike, $1\frac{1}{2}$ to 2 inches long, and $2\frac{1}{2}$ to 3 inches in diameter. Flowers, about $1\frac{1}{2}$ inches long. Leaves, 6 to 9 inches long, 1.6th of an inch broad; more herbaceous than those of any other species. Native of Abyssinia.

T. Quartiniana.—Flower-stem, 19 or 20 inches high. Flower-spike, 5 or 6 inches long, and about $1\frac{1}{2}$ inches broad. Flowers, a little more than $\frac{1}{2}$ an inch long. Leaves, 12 to 18 inches long and about $\frac{3}{4}$ inch broad. Native of Abyssinia.

T. Grantii.—Flower-stem, 12 to 15 inches high. Flower-spike, 2 to $2\frac{1}{2}$ inches long. Flowers about $\frac{3}{4}$ inch long. Leaves, 12 to 15 inches long, and about $\frac{1}{2}$ an inch broad. Native of tropical Africa, discovered in the Speke and Grant expedition, and named after Major Grant.

T. pumila.—Flower-stem, 19 or 20 inches high. Flower-spike, 3 to 5 inches long, and about $1\frac{1}{2}$ inches broad. Flowers, $\frac{1}{2}$ an inch or more long. Leaves, 12 to 18 inches long, and $\frac{1}{2}$ an inch or more broad. Native of the Cape of Good Hope.

T. præcox.—Flower-stem, 15 to 18 inches high. Flower-spike, 3 or 4 inches long and 3 inches broad. Flowers, about $1\frac{1}{2}$ inches long. Leaves, 2 to $2\frac{1}{2}$ feet long and 1 inch broad, of a pale green

* A variety, *T. U. minor*, from the Zulu district of South Africa, has smaller flowers of a pale orange colour, and leaves seldom more than $\frac{1}{2}$ inch broad. It seems to diverge from the type towards *T. sarmentosa*. Another variety, *T. U. glaucescens*, is dwarf in habit, with glaucescent leaves, and bears splendid large spikes of yellow and scarlet flowers.

colour, not glaucous. Native of the Cape of Good Hope. This species is distinguished by its early flowering, which commences in May.

T. rigidissima.—A most distinct species, easily recognisable by the texture, strong veins, and well-marked denticulations of its rigid leaves, which are from 1 inch to $1\frac{1}{2}$ inches long, and about 1.6th of an inch broad. Flower-stem, about as long as the leaves. Flower-spike, very dense, 3 or 4 inches long, the lowest flowers being very much deflected. Native of Mount Boschberg, Cape of Good Hope.

T. caulescens.—This is the most distinct of all the species of this intricate genus, having a decided stem to the rosette of leaves, like a caulescent Aloe. The leaves are the broadest of all the known species, and the stamens and style are exerted from the perianth from a quarter to half an inch. Native of the Stormbergen Mountains, Albany, U.S.A.

T. Schimperii.—Flower-stem, from 1 to $1\frac{1}{2}$ feet high. Flower-spike, very lax, more so than any other species, about 2 inches long. Leaves, 1 to $1\frac{1}{2}$ feet long, reed-like, smooth, about half an inch broad near the base. Flowers, very much curved, usually yellow, sometimes reddish. A native of Abyssinia, and marked, at a glance, from all the other species, by its long lax raceme.

T. foliosa.—The specimen of this species which Mr. Baker saw in the herbarium of De Candolle was imperfect, wanting the leaves; and Mr. Baker supposes that it may prove identical with *T. Quartiniana* (A. Rich.). Flower-stem, about a foot high. Flower-spike, when fully expanded, from $1\frac{1}{2}$ to 2 inches long; lower flowers, very much deflexed. Native of Abyssinia.

T. comosa.—This species very much resembles *T. pumila* of the Cape, from which it differs mainly by its narrower leaves and smaller bracts. Flower-stem, $1\frac{1}{2}$ to 2 feet high. Flower-spike, very dense, 3 or 4 inches long; lower flowers very much deflexed. Leaves 1 to $1\frac{1}{2}$ feet long, smooth, reed-like, about $\frac{1}{4}$ inch wide near the base. Native of Abyssinia.

T. porphyrantha.—This species is, perhaps, nearest to *sarmentosa*, from which it differs by its very short pedicels, longer purple flowers, and included stamens. Flower-stem, $1\frac{1}{2}$ to 2 feet high. Flower-spike, very dense, about 2 inches long; flowers deflected, purple, without any tinge of red, 1 to $1\frac{1}{4}$ inch long. Leaves 1 foot to $1\frac{1}{2}$ feet long, reed-like, smooth, nearly $\frac{1}{2}$ inch broad near the base. Native of the "Orange Free State," Cape of Good Hope. None of the last six species are in cultivation, and the descriptions here given are from Mr. Baker's notes on specimens which he examined in the herbarium of De Candolle.

All the species of *Tritoma* are very readily multiplied by division of the plants in autumn, and grow well in ordinary good garden soil.

W. M.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Cyclobothra pulchella.—This pretty Californian plant has stood the winter well at York, and is growing as freely as a wild Blue Bell.—Q.

Viola cornuta var. Perfection as an Edging Plant.—This is now in flower in Battersea Park, where it forms dense even edgings of deep green foliage, above which its innumerable lilac flowers stand well out. The effect of this plant, grown in this way is strikingly beautiful.—M.

Gladiolus cardinalis.—This does not bloom well with me. What treatment does it require?—A. [We would recommend you not to separate the corms too much, but to plant them in clusters of considerable size; it will then, possibly, bloom with you.—Ed.]

Irises as Border Plants.—All who have a mixed garden or herbaceous border should at least have half-a-dozen or a dozen of the more striking varieties of this old-fashioned—but not yet beaten—flower. Some of the more beautiful varieties are almost equal to Orchids, for decorative purposes.—D. T. F.

Corydalis nobilis.—During the past six weeks, notwithstanding the unfavourable weather, a large tuft of this plant in a border has been thickly studded with trusses of deep yellow blooms. It is a plant worthy of universal culture for early summer-blooming, and is deserving of a position on rockwork or in borders, in both of which it thrives perfectly, if planted in good sandy loam.—LEP.

Saint Bruno's Lily (Paradisica Liliastrum).—This beautiful Alpine meadow plant, which frequently fails to attain much vigour in borders, and often dwindles away from the attacks of slugs, has for the last few weeks been in fine condition on Mr. Wilson's rock-garden at Weybridge Heath. It is planted in deep sandy peat, and forms strong tufts, with a profusion of snow-white, Lily-like, and delicately-scented flowers.—R.

Grass Garden Walks.—After having been bothered for years by Grass and weed-grown walks, I determined to conquer the enemy by a masterly surrender. I therefore spaded up my walks, adding enough good soil to raise them to a level with the adjoining beds; raked and rolled them till they were firm and even, and then sowed them thickly with "mixed Lawn Grass seed," scratching it in with a rake, and giving a final going over with the roller, and awaited the result. In a very few days (not over three weeks), I had the pleasure of walking on green velvet instead of gritty gravel; and with the help of a lawn mower, and an occasional cutting down of the edges true with a spade, have had no farther trouble with my walks. Always green and pleasant to the foot and eye, never weedy, never muddy, never wet (being above the garden eye), they are perfection.—Cultivator.

THE FRUIT GARDEN.

THE KUMQUAT.

(CITRUS JAPONICA.)

THIS is one of the prettiest and most graceful of all the Orange family, and is well worth cultivation on account of its ornamental fruit alone, especially in collections in which common Oranges are grown. In habit, it closely resembles the little Tangerine Orange, inasmuch as it has finely serrated lance-shaped foliage, glossy, and of the deepest green. The fruit is oblong in shape, and about the size of a pigeon's egg. Its rind is thick in proportion to the size of the fruit, of the brightest orange-yellow, profusely studded or dotted with oil glands; and, when broken, it diffuses a very grateful odour. The pulpy portion is juicy; but differs from that of the common Orange, in having a bitter taste; while the rind itself is sweet and delicately flavoured. This little Orange may be grown in a stove or warm greenhouse, and is valuable as a glossy-leaved evergreen, irrespective of its flowers and handsome little fruit, which look not unlike a richly coloured Coe's Golden-drop Plum.

potted Cherry-trees, that when in bloom there are few plants more sweet and effective. A dozen half-standard Cherries in full bloom make as good a display as a dozen white Azaleas, and stand equally long in bloom. Then, again, a conservatory or greenhouse, where plenty of air can be given, is the very best place for them while setting their fruit—by far the most precarious point in their management. When set they may be moved to a higher temperature, under Peach trees, or to a Vinery just started. By the end of April they will come on in any house, and the last batch may be set out of doors. Some may ridicule the idea of putting Cherry trees in the centre of a dining-table, but, if they saw the effect of a neat-headed tree of this kind covered with blossom, or with ripe fruit, they might be induced to change their minds. Others may say, "Oh! Cherry trees are a great deal of trouble, requiring to be shifted about backwards and forwards." This may be so, but my experience is that there is little got without trouble, and if we compare the labour attending the culture of any ordinary greenhouse plant with that of Cherry trees, there is only this difference, that here we get more return for our trouble; for instead of simply obtaining flowers, fruit follows, and then the only attention necessary until next season is to look to the watering of the roots. The trees are not very liable to insects, the caterpillars and black-fly being their chief enemies, and both these are easily stopped

The Kumquat (Citrus Japonica).

It used to fruit regularly in the tropical house at Syon; and cut fruit-bearing branches have been recently exhibited at South Kensington from Mr. Bateman's gardens at Knypersley, where the plant is still grown for the sake of its handsome fruit. The latter is made into a delicious marmalade or conserve, which is considered by connoisseurs to be superior to that made from any other species of Orange. Like other species of Citrus, it is readily propagated by means of grafting; and it may be grown in a compost of fresh turfy loam, with plenty of water while growing. Our illustration is a representation of a fruit-bearing branch, sent from Knypersley. B.

Forcing Cherries in Pots.—Although the forcing of Cherries in pots is old in practice, there are but few places in England where it is carried out to any extent. This is the more surprising, when we consider the increase of glass accommodation everywhere, and the ease with which they can be managed, by shifting them, as they progress through the different stages, to a proper temperature. It is not in every place that the gardener can afford to give up a whole house to permanent trees, and if he could do so, it is not so easy to find suitable plants for the Cherry-house, without bringing into it troublesome insects. There is also this advantage attendant upon

either by smoking or picking. Cherry trees are forced very successfully in Germany, and mostly in low pits, often furnishing a nice lot of fruit in January. At the Royal Garden at Potsdam whole ranges are devoted to them. I do not remember having seen any in France, Under gentle forcing the trees last good for years; and when planted closely in the form of hedges they can easily be protected by a covering of nets in summer and autumn. Where birds are as plentiful as they are here, no sort of fruit can be got except protection is afforded both to buds and fruit. The May Duke is the only sort fit for pots, and the fruit of this get to be very fine. We generally arrange for the second lot of one year to come first the next.—*Florist*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

New Bigarreau Cherries.—Two new Cherries of this description are figured in this month's *Florist*. One is named Frogmore Early Bigarreau; the other, Bigarreau Noir de Schmidt. Both are fine-looking kinds; the first, yellow shaded with crimson; the second, a kind as dark as the May Duke.

Wash for Fruit Trees.—Put half a bushel of lime and 4 lbs. of powdered sulphur in a tight barrel, slacking the lime with hot water, the mouth of the barrel being covered with a cloth; this is reduced to the consistency of ordinary whitewash, and, at the time of application, half an ounce of carbolic acid should be added to each gallon of liquid. Mr. Saunders, of Washington, who uses this wash largely, says: "I generally apply it in spring, before leaves make their appearance." The wash is applied not only to the stem of the tree, but, to some extent, to the main branches.

THE INDOOR GARDEN.

THE JAPANESE PRIMROSE AS A POT PLANT.

Its style, size, colour, form of leaf and flower, all fit this Primrose to take high rank as a pot-plant. It also bears moderate forcing remarkably well. The leaves are, if possible, greener and more delicately serrated and prettily arched, when grown under glass. They are also safe from being marred by biting east winds and sharp April and May frosts. The flower-stems rise higher, and the whorls of flowers unfold with more confidence, greater freedom, and to a wider measure. Grown near the glass the colour suffers but little; it, however, hardly reaches to the brilliancy and depth of hue to which it attains in the open air. It is, however, exquisitely beautiful, and any loss of depth of tone in the flowers is compensated for by the greater size and more delicate beauty of the leaves. In size, and also in beauty of leaf it is unmatched among Primroses. It fits in nicely with most other flowers, adding richness and variety to the best of them. The colour, that of the deepest pink, is one that is rather scarce; and the habit of the plant and its bold flower-stems give it a distinguished air even among the choicest species under glass. Single plants are effective, but a row on a shelf forms a feature in the greenhouse or conservatory at once unique and rich. It is also admirably suited for vases, window-sills, landings, or staircases. Among the choicest contrasts I have seen for many a day, was a double row, in a long passage, of the old *Saxifraga pyramidalis* and the Japanese Primrose. The plants presented the most complete contrast to each other and in the contrast, and from the distinctive simple beauty of each, there resulted a most satisfactory effect. This old *Saxifraga* is one of the most effective of pot plants. Last year it was associated with blue *Lobelias*, depending from brackets above and drooping from the base of the shelf below, and the result was even more beautiful. The two plants while contrasting exquisitely in colour, harmonised well in grace and delicacy of flower and habit. The *Lobelia* threw out streams of blue upon and from the white; the *Primula japonica* sent a line of the most brilliant pink right through the substance and along the side of the snowy and fluffy *Saxifraga*.

D. T. FISH.

ANOTHER NEW HYBRID SARRACENIA.

DR. MOORE has raised a hybrid *Sarracenia*, the history of which is as follows:—The species selected with a view to crossing were *S. Drummondii* and *S. flava*, the latter to be the seed-bearing parent. The pollen was applied, the usual precautions being taken that neither that of the plant operated on, nor that of any other species then in flower, should affect or interfere with the hoped-for result, and before the summer was over Dr. Moore had the gratification of gathering a ripe capsule of seed. This was in 1868, and the following spring the seed was sown in pots well drained and nearly filled with finely-sifted heath mould. The seed was dusted over the surface and merely covered with a thin stratum of damp bog Moss (*Sphagnum*), a piece of flat glass being laid over this, and the pot being placed in an intermediate or moderately warm house. In about a month or so the young plants began to show themselves. The seedlings indicated a good deal of liability to damp off the following winter, but with those which pulled through there was no after difficulty. As far as foliage, pitchers, and habits could indicate, little time was wasted in waiting for evidence of a successful and interesting cross, and early last month the development of flowers still further confirmed it. This hybrid partakes in a remarkable degree of the characteristics of both parents. In the rich veining and exquisite leaf-painting of the upper portion and lid of the pitchers, as also in its purple-coloured flowers, it bears the impress and likeness of the male parent; while in the habit and less persistent character of the leaves it shows maternal traits. It is very probable that cooler treatment than that which is agreeable to *S. Drummondii* will suit it. This hybrid *Sarracenia* was one of the lions of the recent international exhibition at Florence. We believe the plant is to bear the name of the raiser, and will, in future, be known in collections and plant lists as *Sarracenia Moorei*.

Dendrobium citrinum (Bull).—A plant of this species was recently exhibited at South Kensington, and is remarkable for the near resemblance which its flowers bear to those of the well known

D. heterocarpum. Its habit of growth, and time of flowering, however, serve to distinguish it from that species; and its flowers, although slightly fragrant, are destitute of the delicious Violet-like odour peculiar to *D. heterocarpum*, and the little lilac-tipped *D. amnenum*. Its pseudo-bulbs are 3 or 4 feet in length and rather slender, the flowers being 2 to 3 inches across, and of a pale lemon-yellow colour, the lip being set with brown hairs, as in *D. heterocarpum*. The plant reminds me of one grown by a gentleman in the Isle of Man named *Dendrobium Charltonii*.—B.

Flowers for Winter Decoration.—What ought to be done this month to secure the flowering, during winter, of Geraniums, Carnations, or other similar plants? I have plenty of glass and only want to know what to do.—H. V. [To this question, Mr. Grieve, of Culford, has kindly furnished the following reply: "Let us suppose," he says, "that our correspondent's collection of Zonal Geraniums, or, rather, Pelargoniums, consists of healthy young plants in 4-inch pots, or, if in 6-inch pots so much the better; they should be shifted at once into pots one size larger than those they now occupy, and may be placed out-of-doors in a somewhat shady situation; but they will succeed better in a cold pit, placing the lights (the glass of which should be slightly obscured by some shading) over them during hot sunshine, and to protect them from heavy rainfall. When the plants have well filled their pots with roots, let them be shifted into their flowering pots, which should be their last shift for the season; the pots for this last shift may be some 8 or 10 inches in diameter. Stake and tie out the branches as may be required, regulating the development of the plants by stoping the ends of the strongest shoots in order to induce a compact and bushy habit. Pick off every truss of bloom as soon as it appears, and turn the plants frequently round. When the pots are well filled with roots, say about the middle or end of August, weak manure-water may be given about twice a week; and about the middle of September the plants should be taken into the conservatory or greenhouse, and up to this time they should not have been allowed to produce a single truss of bloom. They, however, may now be allowed to do so, and will at once commence to flower freely, and will continue in that condition until Christmas is passed, when they will require to be placed as near as possible to the glass; and the temperature should be slightly increased, to say about 50° as a minimum, when the plants will continue to bloom, though somewhat less profusely, throughout the entire winter. With regard to Carnations, there is a section of this family known as the winter-flowering kinds, which should now be growing in the open air under liberal treatment, and should be placed in the greenhouse about the beginning of October, when they will continue to flower throughout the winter. Roses, and other plants, intended to be forced into flower in winter, or early in spring, should now be enjoying comparative rest on the north side of a wall, or similar position, and should be placed in gentle heat early in November to be had in bloom during the following January."]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Solanum betaceum.—It may interest your correspondent "W. M." (see p. 428), to hear that this plant has been grown in the great temperate house at Kew, for the past eight or ten years under the name of *Cyphomandra betacea*. In habit the plant is not unlike a tall *Brugmansia*, and its vermilion-coloured fruits are borne freely in clusters of from 3 to 7 inches each.

Epiphyllum truncatum.—What should this be grown in? Any hints, in short, as to its management will be gladly received.—A SUBSCRIBER. [Epiphyllums succeed in well-drained pots, filled with fibrous loam and sand. They like a sunny position near the glass and plenty of water during the summer months, but in winter they should be allowed to get nearly dry, or they are liable to rot off at the collar, especially if on their own roots. We, however, presume your plants are grafted on either the *Pereskia* or *Cereus*.—E. F.]

Plants for a Miniature Rock-garden.—Can you recommend a few plants, succulents, Alpines, or others, which will have a nice fresh green look, and good flowers, grown in pockets in rock-work on the sunny side of a Fernery under glass, which is too hot for Ferns to do well? I want something which will stand through the winter without any heat, beyond what it will get from the Fernery being off the drawing room?—I. S. H. [Mesembryanthemums of different colours will succeed perfectly in such a situation, also *Sedum Sieboldii*, *Lysimachia Nummularia*, and some of the Mossy Saxifrages.—Ed.]

Shading by Whitening the Glass.—We have found no mode more simple than skim-milk, with a little powdered whitening mixed with it (say as much whitening as the size of a Walnut), reduced to a fine powder, and thoroughly mixed with two or three quarts of milk. We should advise those trying the scheme to do a piece of glass first. Let it dry, and add to the milk or whitening as less or more shading is required. If it be put on quickly and thinly by one man with a brush, and another follow with a dry duster-brush, merely daubing it quickly with the points of the dry brush, the shading will have the appearance of shaded ground glass, and look neat.

Effect of Coal Gas on Plants.—A small land-holder on the Continent, says the *Moniteur Horticole Belge*, not having a conservatory at his disposal, wintered his plants in a cellar, as is often done. Here, with a little attention, he succeeded in keeping them in tolerably good condition, when an escape of gas occurred from a defective pipe, which was unnoticed for some time. Its effect on the plants was most disastrous, causing the leaves to fall even before they had time to turn yellow. The foliage of *Pittosporums* in particular suffered, being completely destroyed in about twenty-four hours from the first escape of the gas.—M.

THE GARDEN IN THE HOUSE.

A WELL-ARRANGED DINNER-TABLE.

HAVING just seen a very charming arrangement of choice flowers and elegant plants used for the decoration of a dinner-table in rather a novel manner, I propose to offer a few explanatory notes on the subject. The display was in the dining-room of a city club, the main object of attraction being the decorations on a circular table, about 10 feet in diameter. This table is lighted from above by an elegantly designed chandelier, an arrangement of no small importance, as all shadows are then reduced to a minimum, and thrown equally on all sides, when, as in this case, the design is of a geometrical character. The centre was occupied by a circular bank of fresh green Moss, arranged in two semicircular zinc pans, the latter being designed to prevent the cloth becoming damp or soiled by contact with the wet Moss. This bank was neatly rounded towards the centre, from which an elegant plant of *Thrinax elegantissima* (one of the best of all the Fan-leaved Palms for the purpose) rose graceful in outline, the ends of the fresh green segments drooping on all sides, while the mossy bank at its base served as a cool bed for a few choice exotics. These last consisted of Gardenias, whose snowy flowers and glossy green leaves were as fresh as when cut from the plants; and with these some Cactus flowers, of the most brilliant crimson, contrasted most effectively; while side by side with them lay great clusters of the sweetly perfumed and pearly *Stephanotis*, mingled with the refreshing green of *Selaginella Kraussiana* (hortensis). This last-named plant is invaluable for purposes of this kind; for when, as in this instance, it is grown in small pots, the latter can be concealed in the Moss, or they can be turned out of the pots and laid on the zinc pans, the earth being concealed with gently arching Fern fronds (as in the present instance), fresh *Sphagnum*, or *Hypnum* Moss. The fresh green spray of this *Selaginella*, and the equally graceful *Lygodium scandens*, had a very fine effect, carelessly rambling on the snowy cloth, or twined gracefully round the slender rising stems of the Palms. At a little distance from this central group were arranged six trumpet-shaped vases, equi-distant, in a circle. These vases were about 2 feet and a half high, and were connected with each other by a graceful arch of wire draped with the fresh sprays of *Lygodium scandens*. All of them were very tastefully filled with Ferns and a few choice Orchids and exotics. The principal Fern used in these vases was *Pteris serrulata* major, around the mid-rib of which a piece of steel wire 6 or 7 inches long was twisted, so that the fronds could then be adapted to any degree of curvature, by which means they were, if possible, rendered still more graceful than is usually the case. Along with these were sprays of *Phalanopsis amabilis*, wired in a similar manner, the individual flowers of which forcibly reminded one of great moths of snowy whiteness; flowers of *Cattleya Mossiæ* had lips resplendent with crimson and gold, while their great windmill-like sepals and petals were faintly suffused with the softest rosy-lilac. Other rare Orchids employed were *Oncidium ampliatum*, with its soft golden-yellow flowers; *Cattleya intermedia*, with pearly segments and a bright amethyst-coloured lip; while the weird-like spikes and long antennæ-like flowers of *Brassia verrucosa* reminded one more of an insect than an Orchid. Outside the circle formed by these tasteful vases were half-a-dozen select little dinner-table plants, veritable models of lightness and grace. These consisted of choice Palms, of which the slender plumose *Dæmonorops fissus*, and *D. palembanicus*, may be mentioned as types; and other elegant plants, such as *Stadmannia Jonghii*, and the fresh feathery-leaved *Jacaranda mimosæfolia* may be taken as excellent examples; other Palms of larger size, say, from 3 to 4 feet high, consisted of the slender-stemmed *Oreodoxa regia* and the graceful *Euterpe edulis*. This arrangement was one of the best we have ever seen, as in no way was the view across the table intercepted, this being too frequently the case where thick bushy-habited plants are employed. The table was laid for sixteen persons, and before each guest was placed a neat little specimen glass with a bowl-shaped vase or finger glass,

the latter being half filled with water in which two or three pips of a double scarlet or pink *Pelargonium* floated along with a spray or two of Fern or *Selaginella*, while the little vases above each contained a choice button-hole bouquet, no two being exactly alike, and variously composed of Tea-Roses, *Erica ventricosa*, rare Orchids, and delicate Ferns.

F. W. BURBIDGE.

A Hint to Window Gardeners.—There are many who grow flowers in windows that do not care to go to the expense of boxes; and, where pot-plants are chiefly grown, boxes are scarcely essential, as the pots can, of course, be set on the sill outside. The pots, are, however, rather unsightly, and, to obviate this drawback, a neighbour of mine has ingeniously contrived to hide them. He procures a board about 8 inches broad, and half an inch in thickness, the length varying according to the width of the window. This board is fixed to the masonry on each side, and can be painted any colour, which will harmonise with its surroundings, and, if desired, it can be fixed so as to project an inch or two from the front of the sill by means of iron holdfasts. This gives more space behind for the plants. This simple contrivance hides the pots from view in front, and also shades them from bright sunshine, which often ruins delicate-rooted plants. It, also, effectually secures the plant from falling, and is much better, in this respect, than the string or wire generally used for that purpose.—F. W. B.

Ivy for Indoor Decoration.—I do not know a single plant that will stand so much hard usage as Ivy. The only point on which cultivators err is not keeping its leaves clean. If it be well washed two or three times a week, and the soil well watered, it will grow for weeks, and even years, without danger from change of temperature. A vase, not necessarily costly, will answer well for Ivy; and this reminds me of Mr. McNab's excellent plan of growing it in vases. Long shoots of the Ivy were procured, with the young and tender aerial roots very abundant; the lower ends were wrapped in Moss, and then some five or six of these were tightly tied together at the bottom and placed in the vase. The latter was filled within a few inches of the top with water, and the ball of Moss suspended therein. Thus managed, the roots soon commence to grow; afterwards the Moss need not quite reach the water, as the roots will extend down into it, and prove all-sufficient. So many very beautiful varieties of Ivy are now in cultivation that, by selecting kinds that will form a decided contrast in shape and colour, the effect may be materially heightened. The centre of the vase may be filled with cut flowers, or Grasses, or, indeed, nothing would look better than Ferns. The Ivy may be allowed to hang down over the sides of the vase in graceful festoons, or else trained over and around the window, thus making a room appear cheerful and pleasant all the winter through. It is not necessary, and, in fact, I do not believe that Ivy will grow as well in strong light as when it is in a partially shaded position, as it likes shade and an even cool atmosphere. I have known instances where Ivy has been grown in large tubs, and trained up a staircase, thus forming a mass of green foliage from the hall below to the floor above. Planted in a box, and run over a low trellis, it makes a lovely window screen even in towns. Used in any way, in fact, as fancy directs, it is unexcelled as a house plant.—J. H.

Preservation of Wooden Labels.—Thoroughly soak the pieces of wood, of which they are made, in a strong solution of sulphate of iron; then lay them, after they are dry, in lime water. This causes the formation of sulphate of lime (a very insoluble salt) in the wood, and the rapid destruction of the labels by the weather is thus prevented. Bast, mats, twine, and other substances used in tying or covering up trees and plants, when treated in the same manner, are similarly preserved. At a recent meeting of a horticultural society, in Berlin, wooden labels, thus treated, were shown, which had been constantly exposed to the weather during two years, without having been affected thereby.

How to Test Impurities in Water.—A small and simple apparatus for detecting organic and other impurities in water, has been recently brought out by the Water Purifying Company, 157, Strand. The apparatus consists of a neat roan case in which are seven small tubes containing the standard test fluids—ammonia, organic matter, lead (positive and negative tests), carbonate of lime, sulphate of lime, sulphuric acid and iron, with test-tubes and dropping glasses complete. The apparatus has been tried on several occasions with waters of different kinds, and in every instance has been found to answer the purpose for which it is designed.

THE PAPER-REED OF THE ANCIENTS.

(CYPERUS PAPYRUS, OR PAPYRUS ANTIQUORUM.)

It is not commonly known in gardens that the graceful plant, grown as the Papyrus of the Nile, is really another species, and that the true Papyrus is not in cultivation. Some years since, Professor Parlatores, in the "Mémoires par divers Savants Etrangers, Institut Impérial de France," pointed out the difference between the true Papyrus of the Egyptians (Papyrus nilotica, vel ægyptiaca) and the plant which has hitherto been grown in botanic gardens under that name, but which is, in reality, the Syrian or Sicilian species (P. syriaca, vel siciliana). The former has been described and figured by Bruce, in his "Travels," vol. vii, p. 115, and differs so much in appearance from the Syrian plant, that it is impossible, on seeing both, to mistake one for the other. The distinction will be at once perceptible from the accompanying illustration, in which we reproduce M. Parlatores's drawings of the two plants. In the Syrian Papyrus, the inflorescence takes the form of a globose umbel, and the involucre is reflexed; while, in the true Egyptian plant, the umbel is of an erect brush-like shape, with the involucre also erect. The Syrian plant also grows to a greater height—from 8 to 16 feet; while the true plant is generally not more than 5 or 6 feet high, and seldom reaches as much as 10 feet. These points of difference are at once patent to any observer. There are, however, several minor distinctive characters which the botanist will appreciate in the following minute descriptions of the two plants, by M. Parlatores, from specimens in his possession.

Cyperus syriacus, Parl.

Umbel, decompound, globose, with very numerous long and slender rays, the upper ones of which are erect; the middle or lateral ones longer, curving downwards; and the lower ones shorter and pendent. General involucre consisting of several divisions, much shorter than the umbel, the outer ones reflexed, pendent; partial involucre, of three (rarely four) linear thread-like channelled divisions, rough on the margin in the upper part, elongated, always much shorter than the rays; spikelets, narrowly linear, somewhat distant from each other; glumes, ovate, obtuse, paleæ, linear-lance-shaped, acuminate, somewhat longer than the seed, or achene, which is oblong, triquetrous, convex-angled on the outside, concave within, obtuse at the apex, smooth, of a tawny colour, about half the length of the glumes. Stem, tall (from 8 to 16 feet), triquetrous in the upper part, obtuse-angled at the base, generally leafless, and merely covered at the base with five or six acuminate sheaths. When leaves occur, they are broadly linear-lance-shaped, acute, keeled, rough with small teeth towards the top. Rhizome, thick, creeping. Native of Syria and Sicily, in shallow and slow-flowing streams. It is also found in Italy, in marshy places, not far from the Gulf of Genoa, between 32° and 38° of north latitude. Flowers from July to September.

Cyperus papyrus, Parl.

Umbel, decompound, erect, somewhat nodding at the top; rays, very numerous, long, all erect, the upper or central ones longer than the others. Divisions of the general involucre, numerous, much shorter than the umbel; outer ones erect, spreading; divisions of the partial involucre, from four to six, narrowly linear, channelled, rough on the margin in the

upper part, very long—longer than the ray. (Flowers and fruit wanting in specimen.) Stem, from 5 to 6 feet (seldom as much as 10 feet) high, triquetrous, obtuse-angled; covered, for one-third from the base up, with numerous acuminate sheaths. Rhizome, thick, creeping. Found in marshy places in Upper Nubia, near the banks of the White Nile, at about 7° of north latitude; and in Abyssinia, between 9° and 13° of the same latitude. The preceding account of M. Parlatores was published in 1854; but, since that time, the true Papyrus has been discovered in Palestine by the Rev. H. B. Tristram, who read the following paper on the subject before the Linnean Society:—

During my travels in Palestine, in 1864, I was pleased to find a Papyrus growing luxuriantly by the shores of the Lake of Galilee, close to the Ain et Tin, on the north of the plain of Gennesaret. Some stems, which I measured, exceeded 16 feet in length. I afterwards found, in the almost inaccessible marshes of the Huleh (the ancient Merom) many acres of the same plant. It is noticed by Dr.

Thomson in his "Land and Book," who gives a fair popular description of the plant under its familiar Arabic name of Babeer, but without knowing that the classical and modern Papyrus is simply a form of the original Babeer. The stems are cut down by the Bedouins for a less noble purpose than they served under the fostering care of the Pharaohs, viz., for the thatching of their huts and roofs, and for mats, and the roots are collected for fuel. I preserved, unfortunately, but one specimen from the Lake of Galilee, and none from Merom. Since the Papyrus syriacus is well known as growing on the plains of Acre and Sharon, I was assured that this must be the same. Feeling, however, some suspicion on the subject, I forwarded my specimen to Professor C. C. Babington, of Cambridge, who assures me that he has no doubt of its being the true *Cyperus Papyrus*, and not the plant usually cultivated under that name, which is the *Cyperus syriacus* of Parlatores. I regret that, at the time of my visit, the seeds were not ripe, as Professor Babington informs me that no living specimen of the true *Cyperus Papyrus* exists in our botanical gardens. He also adds that it is only known now to grow in marshes of the White Nile, in Nubia, 7° north, but is lost in Egypt, and that my discovery, though simply a corroboration of the statement of Bruce ("Travels," vol. vii., p. 115,) may be of some

interest. It appears to me that the discovery of this species so far north as the upper end of the Lake of Galilee is important when viewed in connection with our discovery of so many African species of fish in that lake; the more so as the ornithological and mammalian forms which recall the African fauna do not extend so far up the Jordan basin, and it was to the south of the Dead Sea that we obtained most of our African types, as shown by Mr. Lowne in his paper on the flora of the Wady Zuweirah.

Although this famous plant has now become quite extinct in Egypt (the country with which its name is historically connected), it still abounds in the waters of the Upper Nile. In his recent work, "The Heart of Africa," Dr. Schweinfurth thus describes his impressions on first beholding it growing in luxuriance in one of the Nile channels, named Bahr-el-Ghazal: "To me, botanist as I was, the event elevates the day to a festival. Here, at a latitude of 9° 30' N., are we now first able to salute this sire of immortal thought, which, centuries ago, was just as abundant in Egypt, as at present it is on the threshold of the central deserts of Africa. I was quite lost in admiration of the variety of production of the surface of the water, to which the antique Papyrus

True Egyptian Papyrus.

Syrian Papyrus.

gave a noble finish. It strikes the gaze like the creation of another world, and seems to inspire a kind of reverence. Although for days and weeks I was environed by the marvellous beauties which enrich the flora of the Nile, my eye was never weary of the apparition of its graceful form."

The plant is pretty generally known as that which yielded the paper of the ancients, which was made from the inner bark of the stem. This is composed of thin laminæ or layers, and these when unrolled and placed together formed a sheet. The layers obtained from near the centre were the best, and each layer diminished in value, in proportion to its distance from that part of the stem. When carefully peeled from the plant, and dressed at the sides, that these might join evenly, these layers were laid close together on a hard flat table, and then other pieces, similarly cut, were laid across them at right angles. They thus formed a sheet of many pieces, and, to

are yet in a wonderful state of preservation. They are generally found thrust into the breast, or between the knees of the mummy, and occasionally they are enclosed in small wooden boxes or in purses. The rolls are always compressed; sometimes their exterior is ornamented with gilding, in which case they are looked upon as of superior value. In the museum of Naples, there are not less than from 1,700 to 1,800 MS. Papyri, which have been dug from the ruins of Herculaneum, and yet only a very small portion of that ancient city has been dug out of the mass of lava by which it was overwhelmed. The writing on many of these MS.S. is very clear and distinct, but it may be doubted whether the paper produced from this substance, even when the art was in its perfection, and the best Papyri of the Nile were employed, ever equalled the paper now made from linen rags in any one quality except durability. In Sicily, the Syrian Papyrus

The Syrian Papyrus on the River Anapus, in Sicily.

promote their adhesion, the whole was moistened with the water of the Nile, and, while wet, pressure was applied. The glutinous matter inherent in the bark was the main cause of the adhesion of the layers. The sheets were afterwards dried in the sun, and were then again pressed, and smoothed, and flattened by being beaten with a wooden mallet. In some cases, when the plants themselves did not contain sufficient juice, or when the water did not dissolve the juice properly, the layers were joined together with paste, made of fine flour, mixed with hot-water and a little vinegar. The ancient Egyptians made their sheets of prodigious length, though narrow. One of those, purchased by the Earl of Belmore, was 14 feet long by 1 foot broad; and Belzoni had a Papyrus 23 feet long by 1½ broad. The quantity of the Papyrus used by the Egyptians in their funeral ceremonies, alone, must have been very great. The Papyri now found in the ancient tombs and mummy caves of Egypt

occurs in great abundance in the river Anapus, near Syracuse. A recent traveller thus describes its appearance in this locality:—

The river Anapus, after flowing through an alluvial plain, which requires draining very much, being in many parts swampy, and emitting the most unhealthy miasmata, falls into the sea at the west side of the magnificent harbour of Syracuse. We ascended the river for some distance in a flat-bottomed boat. Near its mouth the water was pretty deep, but muddy; and a little farther on we found it contaminated and obstructed by heaps of Hemp, which were steeping there. The current was scarcely perceptible; but our progress was impeded by aquatic plants and strong high rushes, which, in many places, so covered the river from side to side, that we could scarcely see the water. At the distance of about an Italian mile from the mouth of the river, we first came in sight of the object of our search, the graceful Papyrus plant, which we saw growing in little clusters, and shooting above groups of Water Lilies on either side of the river. A quarter of a mile higher up, we turned

to the westward, and quitting the main stream, entered the Cyanean branch, which here forms its junction. This branch was still more covered with Reeds and aquatic plants than any other part we had come through; but, unlike the Anapus, its water, when visible, was as clear as a mountain stream in Scotland. In proportion as we proceeded up this branch, which is very winding and deep, we saw the Papyrus in thick groups; and, as we laboured to force our way through the rich vegetable obstruction, which became stronger and stronger, the beautiful feathery tufts of the plant bending with its slim elastic stem, frequently flapped in our faces. At a short distance from the fountain head, the serpentine stream was so completely choked up with a vegetation of surprising tenacity that, having no man to tow us along from the banks, and indeed, no assistance but such as a little boy from Syracuse could render us, we were well nigh giving up our farther progress, for the present, in despair. Persevering, however, by cutting, and tearing, and forcing our little punt through or over this matting of plants and flowers, we at last shot into the clear basin of the Cyanean fountain, well bathed with perspiration and its own waters. This famous fountain, which, coming by the winding course of the stream that flows from it, may be somewhat more than half a mile from the Anapus, is a circular pool, of from 60 to 70 feet in diameter. Its waters, though the bottom of the basin seems formed of black mud, are remarkably pure, and so transparent that you can see the fish which swarm there, and any other object, far beneath the surface, as clearly as though you looked through the medium of a transparent atmosphere. According to our measurement, the fountain was then 32 feet deep;—it was fringed all round with the graceful Cyperus. Nothing remained of the ancient temple of Cyane except some blocks of marble, that had fallen or been thrown into the fountain; even the name of Cyane was no longer known there, the Syracusans calling the fountain and the stream La Pisma. Few spots could be more solitary, and still the limpid water flowed without a ripple, nor were any sounds heard except the occasional twitter of a sort of Reed-sparrow, and now and then the rustling of the high Papyrus, and other aquatic plants, as they were shaken by a breath of summer air, or agitated by the fish gliding among their roots. The Papyri fringing the pool seemed literally to float upon its tranquil waters, their principal root, which is large and bulbous, running horizontally at the surface of the stream, and long slender filaments depending perpendicularly from it, like so many little cables to keep it at anchor. The shaft or stem proceeding from this root was frequently 10 feet high, without measuring the flowing tuft in which it terminated. From some of them which we cut down and carried away with us, we easily made a sort of paper, though I cannot say much of the quality we produced, being hurried and without proper implements. We were obliged to fasten the strips together, to form one sheet, with gum, which may have arisen from the Syracusan Papyrus being deficient in the glutinous quality of those of the Nile, or, which is at least as probable, from our not dissolving it properly, or not giving the strata sufficient pressure. Some manufactured Papyri we saw in the house of a gentleman of Syracuse were certainly infinitely superior to our own, though even those would have been a poor substitute for our English writing-paper of the very worst quality. They were specimens of the result obtained by an antiquary called L. Cavalier Landolina, who, a good many years before, had endeavoured to revive the ancient manufacture, confidently anticipating that it would supplant paper, not only in Sicily, but in all Europe.

Our last illustration is from a sketch taken on the Cyanean branch of the river Anapus, and shows the luxuriant growth of the Syrian Papyrus in that district. W. M.

Sociable Plants.—Under this heading, M. Lebas makes the following remarks:—In a state of Nature, certain plants are always found growing singly by themselves, while, others are as invariably found growing together in groups. He thence infers that the former are influenced by some mysterious antipathy against, and the latter by an equally strong sympathy for, each other. He instances the case of the Common Service Tree (*Sorbus domestica*) under cultivation. This, he says, cannot be well grown, if planted by itself, as the plants invariably grow rickety, and always become covered with galls and canker; while, if they are planted among Apple trees, &c., in the same soil, and under precisely the same conditions, they thrive to perfection. He has remarked also, that if seeds of the Service Tree are sown by themselves, the seedlings are always poor and miserable; whereas, if the seed is mixed with Pear seed, the Service seedlings come up vigorously, and often make stronger plants than the Pear seedlings. M. Lebas' account of his experience with the Service Tree is intelligible, on the supposition that these trees grow best when sheltered by others; his experience with the seeds, however, requires confirmation. M.

THE ARBORETUM.

BRITISH ROSES.

WITH the public, generally, the favourite Roses must ever be the fine hybrid kinds, and the public are quite right to prefer these for garden culture. We, however, hope that there may be found many to whom the beauties of the wild single Roses will prove attractive, and that our own British kinds may not be forgotten, but planted here and there in half-wild places. We have, therefore, prepared an abstract of Mr. Baker's exhaustive paper on British Roses. It will serve to show what varied beauty there is among our native wild Roses alone.

Key to the Species.

Group 1. Spinosissimæ.—Low erect compact bushes, with crowded and very unequal prickles, the large ones slender and nearly, or quite, straight; leaves, naked or hairy, never more than slightly glandular beneath; sepals, persistent or sub-persistent.—1. *spinosissima*. Fruit, dark purple; flowers, always solitary.—2. *rubella*.* Fruit, bright red; flowers, not essentially solitary; sepals, truly persistent, always simple, thinly glandular on the back; leaves, quite naked, with simple teeth.—3. *involuta*. Sepals, truly persistent, more or less compound, densely glandular on the back; leaves, more or less, often very, hairy, the teeth generally compound.—4. *hibernica*. Sepals, compound, naked on the back, not fully persistent; leaves, naked or thinly pubescent beneath, simply toothed.

Group 2. Villosæ.—Larger bushes, erect or lengthened out and arching; prickles, uniform, scattered, slender, scarcely at all hooked; sepals, persistent or sub-persistent, always densely glandular on the back; leaves, generally very hairy, and inconspicuously or not at all glandular beneath.—Sepals, truly persistent; fruit, ripening early, with no disk. 5. *pomifera*. Bush, arching; sepals, copiously compound. 6. *mollissima*. Bush, erect; sepals, sparingly compound.—Sepals, not truly persistent. 7. *tomentosa*. Fruit, later in ripening, with a distinct disk like that of *canina*.

Group 3. Rubiginosæ.—Smaller bushes than in the last and next group, erect or arching; the prickles, scattered, stouter downwards, and decidedly hooked, sometimes with a few aciculi mixed amongst them; leaves, thinly hairy or not at all hairy, but always densely glandular over the under surface; sepals, sub-persistent.—8. *rubiginosa*. Very odorous; bush, erect and compact.—9. *micrantha*. Arching bushes without decided Sweet-briar fragrance; prickles, uniform; flowers and leaves small; styles, naked; peduncle, generally aciculate.—10. *pulverulenta*. Prickles, often with a few bristles intermixed; flowers and leaves, larger; styles, hairy; peduncle, rarely bristly.

Group 4. Caninæ.—Larger bushes, always lengthened out and arching; prickles, uniform, scattered, decidedly hooked, and thickened downwards; sepals, deciduous or sub-persistent, usually naked on the back; peduncle, generally naked, and leaves naked, or but thinly hairy, and not at all glandular over the surface.—11. *canina*. The only species.

Systylæ.—Styles, united into a slender column, which is protruded beyond the disk; arching or trailing bushes; prickles, uniform, stout, hooked; sepals, deciduous; fruit, late in ripening.—12. *stylosa*. A high arching bush like *Canina*, with copiously compound sepals; the style-column shorter than the stamens. 13. *arvensis*. A low trailing bush, with short slightly compound sepals and a style-column equalling the stamens.

Group 1.—Spinosissimæ.

R. spinosissima (Linn.).—Stems, usually quite erect, 1 to 3 feet high, with short stiff compact branches. Prickles, very dense. Branches, often bright reddish-brown. Full-grown leaves, 1½ to 2 inches long, with seven or nine oblong leaflets. Corolla, 12 to 18 lines across when expanded, white, with a yellow throat, rarely variegated with red. Disk, none. Fruit, depresso-globose, dark purple, with a dark purple juice; 5 to 6 lines broad, quite naked, crowned with the erect persistent sepal; changing colour in September in the low country in England. In Britain, extending from the south of England to Caithness, ascending in the north of England to 500 yards above the sea-level, and in the Scotch Highlands to nearly 600 yards, and in Ireland also reaching from the north to the south, with a preference for the sands of the seashore, and inland for limestone. Though it is the only Rose known in Iceland, yet in Scandinavia it is much less boreal in its range than *mollissima* or *canina*, being restricted, like *tomentosa*, to the south-west. It is universally distributed through Central and Southern Europe, reaching the Barbary States, Cashmere, and, through Siberia, to the north of China (Prof. Bunge). Though it varies much, according to its place of growth, in

* This, and *pomifera*, though introduced in the key, have, as will be seen, no fair claim to be regarded as British plants.

luxuriance and the density of its prickles, we do not appear to have in Britain any striking variety. With us, the form with a naked peduncle is much the most common, that with an aciculate peduncle quite rare. Lindley's var. *platycarpa*, is a small Irish form with an aciculate peduncle, his var. *turbinata*, another small form with turbinate fruit, and his var. *reversa*, another small form with slender deflexed prickles and ovate fruit. The form with the flowers variegated with red, *R. Ciphiana* (Sibbald) is the parent of many of the garden Scotch Roses. A plant with red fruit was gathered by Mr. Borrer, in Sussex, and another with ovate-urceolate fruit by Mr. Jackson, in Scotland, and Mr. Robertson, in Durham. Var. *pilosa* (Lindl.) evidently does not belong here, but to *R. involuta*. *R. sanguisorbifolia* is a mere form of this, with nine to eleven leaflets. The principal European varieties are:—*R. Ripartii* (Déség.) with doubly-toothed leaves, more decidedly glandular petioles and stipules, and peduncles usually, but not always, aciculate; *R. consimilis* (Déség.) with glabrous styles, unarmed and glandular petioles, and simply toothed leaflets slightly hairy on the mid-rib beneath; *R. spreta* (Déség.), with less numerous prickles, thinly hairy styles, and unarmed petioles; and *R. myriacantha* (DC. Lindl.) a stunted, compact, erect plant with very long and very dense prickles, doubly-toothed leaflets densely glandular all over beneath, deep-red flowers, peduncle, and usually the calyx-tube, densely bristly and hairy, and simple sepals densely glandular on the back. Other varieties are the Siberian *R. altaica* (Willd.), *R. grandiflora* (Lindl.), and the Himalayan *R. unguicularis*, Bert. Misc.

***R. rubella* (Smith).**—A bush with just the general habit of *spinosissima*, but the prickles more slender and fewer in proportion to the small setaceous bristles. Full-grown leaves $1\frac{1}{2}$ to 2 inches long, with seven to nine leaflets, which are just like those of *spinosissima* in texture, but more oblong and more sharply toothed. Flowers, usually solitary, but occasionally in twos. Corolla, cream-coloured, or often variegated with red, 12 to 18 lines across when expanded; the styles densely villose. Fruit, bright-red, changing colour in England early in September, usually but not invariably drooping, roundish or short ovate-urceolate, 6 to 8 lines long; the sepals fully persistent. Disk, none. This is a plant well-known in botanic gardens. It is very like *spinosissima* in habit and prickles; but the fruit is different, the peduncles are always bristly, the sepals are glandular on the back, and the flowers not always solitary. *R. stricta* of Muhlenberg (a plant attributed to Pennsylvania, no doubt in error, as it has never been gathered in recent times), and *R. Candolleana* (Thory), do not appear to differ from it by any tangible characters, and the Himalayan *R. Webbiana* (Wall.) is very nearly, if not absolutely identical with it. There are specimens in several herbaria labelled as having been collected by Winch on the sands of the seashore south of Shields Law on the Durham side of the Tyne; but Winch certainly did not know it clearly, for a plant collected by Mr. Hogg, near Hartlepool, which he called *rubella*, is only ordinary *spinosissima*, and it is probable that some confusion has arisen. I have not seen specimens complete enough to be able to form a clear opinion as to what are the relations to this of *R. reversa* (Waldst and Kit.); but the difference, if any, must be very slight. Dr. Thomson's extensive suite of specimens from the Himalayas appear to run this by gradual stages into *spinosissima*. My specimens from the Alps are too few to show fairly what may be the case there; and, on the other hand, as will be seen, it comes exceedingly near to some of the varieties of the next.

***R. involuta* (Smith).**—Though *involuta* is the name which has the right of priority, yet the variety called *Sabini* is much the most common, and I therefore take it first.—Var. *Sabini* (Woods). In exposed places, an erect shrub 2 to 4 feet high, with short compact branches, with dense prickles passing down by gradual stages into bristles; in shade or hedges, sometimes drawn out and arching. Well-developed leaves of the barren shoots, $2\frac{1}{2}$ to 3 inches long; the upper surface thinly grey-pubescent, the lower more so, and often slightly glandular. Flowers, one to three, varying from pure white to deep pink, $1\frac{1}{2}$ or even 2 inches across when expanded. Styles, densely villose. Sepals ascending after the petals fall, quite persistent upon the erect roundish red fruit, which measures 7 to 8 lines each way, and changes colour in the north of England late in September or Early in October, and is only produced very sparingly. Disk, none. Sparsely distributed through Britain, from the Isle of Wight and Sussex, northward to Caithness, ascending to 300 yards in Yorkshire. It appears to reach its maximum of frequency in the north of England. Several stations are known in the north of Ireland. *R. gracilis* (Woods) is not more than a robust condition of this variety with the prickles, like the rest of the plant, abnormally stout, and a little curved.—Var. *Doniana* (Woods). A form found in dry exposed situations, with leaflets more densely hairy than in the last, and consequently greyer-green and softer. Calyx-tube and fruit, densely prickly; Flowers solitary, and sepals hardly, if at all, pinnate.—Var.

gracilescens (Baker). A robust form, gathered in county Antrim by Dr. Moore, with leaves 3 to $3\frac{1}{2}$ inches long, ovate leaflets, thinly hairy on both sides, not at all glandular beneath, with copiously compound tothing, the terminal one 15 to 16 lines long, by nearly an inch broad. Petioles, with few or no bristles and glandular hairs. Flowers, three to six, in a cluster. Bristly peduncles, and naked elliptical calyx-tube.—Var. *Robertsoni* (Baker). Intermediate between *Sabini* and the original *involuta*. Leaflets, with the teeth sharper and less compound than in *Sabini*; glabrous (when mature), on the upper surface, hairy principally on the ribs, and inconspicuously glandular beneath. Calyx-tube sometimes, but not always, naked. Sepals, as compound as in *Sabini*.—Var. *Smithii* (Baker). A stunted erect bush, with leaflets naked when mature on the upper surface, hairy principally on the mid-rib beneath, and scarcely at all glandular, the serrations closer and sharper than in all the preceding forms and but slightly compound. Flowers, solitary, the peduncle and calyx-tube densely bristly, the sepals simple. The only British specimens I have seen well representing this variety were gathered in Arran and near Richmond, in Yorkshire.—Var. *laevigata* (Baker). Peduncle and calyx-tube quite naked, the latter depresso-globose. Leaves, like those of *Sabini* in clothing and tothing. Petioles, villose and glanduloso-setose, but scarcely at all aciculate. Sepals, all quite simple and not glandular on the back. Gathered near Broughton Spa, West Yorkshire, and a similar plant in Antrim and Derry.—Var. *Moorei* (Baker). Prickles, stouter than in any of the other forms. Leaflets, nearly naked above, thinly hairy and densely glandular beneath, the serration like that of var. *Smithii*, the petiole scarcely at all hairy. Flowers, one or more.—Var. *occidentalis* (Baker). Very near *Wilsoni*, but the leaves smaller, slightly hairy beneath. Peduncle, densely aciculate and glanduloso-setose. Calyx-tube, globose, naked, the main sepals not more than half-an-inch long, with one or two setaceous pinnæ on each side. Described by Lindley from an Irish specimen still in the Hookerian herbarium, the exact station not known.—Var. *Wilsoni* (Borrer). An erect bush 2 or 3 feet high, with deep vinous purple branches and leaves, and stipules often suffused with the same colour. Prickles, as in *Sabini*. Flowers, one to three, full pink. Fruit, with more of a tendency than in *Sabini* to an ovate pitcher-shape; when well developed, 8 to 9 lines long by half-an-inch broad. Banks of the Menai, near Bangor and at Umbra rocks, county Derry. It will be seen by the descriptions that the extreme forms placed here run into one another by very gradual stages. *Doniana* is like reduced *mollissima*, with crowded unequal prickles, whilst *Wilsoni* touches close upon *rubella*, and *Moorei* approaches some of the *Rubiginosæ*. It is noteworthy that a plant so widely spread in Britain, and with so many varieties, should be so rare upon the Continent. It is known only in two widely separated tracts—the provinces of Namur and Luxemburg, in Belgium, and upon Mount Salève, near Geneva.

***R. hibernica* (Smith).**—In exposed places an erect shrub 3 or 4 feet high, but in hedges drawn out and slightly arching. Prickles, less crowded than in *involuta*, but running gradually down into setaceous bristles in the same way. Leaves of the barren shoot, 3 to 4 inches long; the upper surface a slightly glaucous green, naked or inconspicuously hairy on the mid-rib, the lower surface thinly hairy on the veins, not at all glandular. Flowers, generally one to three, but sometimes up to a dozen. Corolla, pale pink, 15 to 18 lines across when expanded. Styles, densely hairy. Sepals, ascending after the petals fall, but not fully persistent. Fruit, roundish, about half an inch long and thick, crowned with a decided disk, not ripening till October. The form with hairy leaves occurs in Derry and Down; and, in England, in Cumberland and Cheshire. A form (var. *glabra*, Baker), with sharper teeth and leaves quite naked, has been gathered in Sutherlandshire, Durham, Cumberland, North Yorkshire, Cheshire, and Surrey; and Dr. Moore has found another glabrous form with larger nearly round leaves and blunter teeth than in the type on rocks at 1,000 feet above the sea-level on Ben Evanagh, county Derry.—Var. *cordifolia* (Baker). Prickles, more slender and denser than in the type, the large ones scarcely curved. Leaves, nearly naked below, the teeth more open and blunter than in the type. Northumberland. No one who has once seen this growing is likely to confound it with any other species. The fruit is different from that of *involuta*; but to all the other distinguishing characters taken singly, some of the forms furnish an exception. In general habit, when in flower, the ordinary glabrous English form has just the same sort of resemblance to typical *canina* that *Doniana* has to *mollissima*.

Group 2.—Villosæ.

***R. pomifera* (Herm.).**—A robust arching bush 4 to 6 feet high, with a trunk sometimes as thick as a man's arm, with dull purplish glaucous branches and scattered, uniform, slender prickles, 4 to 6 lines long. Well-developed leaves, 5 to 7 inches long, grey-green,

but not softly pubescent on both sides as in *mollissima*, the underside often slightly glandular, the teeth open and copiously compound. Flowers, one to three, pink. Fruit, ripe in August, bright red, globose or broadly turbinate, often, but not always, pendent, densely covered with strong prickles. A stronger-growing plant than *mollissima*, with arching branches, larger and more openly toothed, narrower leaves, not so softly pubescent, and larger flowers and fruit, and copiously compound sepals. It is an old favourite in gardens, but seems to possess no fair claim to be considered British. The English specimens gathered of late years, which we have seen, are from Staffordshire, Cotes Heaths, and Gloucestershire. It is a native of Scandinavia, Belgium, North Germany, the Alps, and Jura, reaching the Pyrenees, Apennines, and Tyrol, and, according to Nyman, Castille, Tauria, and Mount Athos. The corolla is often beautifully gland-ciliated, and in cultivated specimens we have seen it 3 inches across.

R. mollissima (Willd.).—Bush erect, 3 or 4 feet high, never arching, with short ascending branches, bright reddish-purple with a glaucous tinge in exposure. Prickles, scattered, uniform. Fully-developed leaves, 4 to 5 inches long, with seven leaflets, generally a paler greyer-green than in any other species, the upper surface always more or less pubescent, the lower more so. Flowers, usually one to three, crimson in bud, deep rose when expanded, rarely white, sometimes gland-ciliated, 15 to 18 lines across when fully open. Sepals, ascending after the petals fall, and quite persistent upon the pulpy globular bright red fruit, which is $\frac{1}{2}$ to $\frac{3}{4}$ inch broad and deep, and ripens before that of any other species, changing colour in the north of England early in August, or even sometimes late in July, and sometimes, but not always, cernuous. Styles, densely villose. Disk, none. From the Humber northward through England and through Scotland, this species appears to be universally distributed, coming next in order of frequency to *canina* and *tomentosa*, to which three species at least 90 per cent. of the Roses of the northern half of our island must belong. *Tomentosa* and *mollissima* often resemble one another so closely, that it is not safe to pronounce upon ordinary herbarium specimens; but the fruit is very different, both in character and time of ripening; and, when growing, the habit of the bushes is different. The following are the most striking English varieties:—*Var. cærulea* (Woods). Leaves, softer and greyer than usual, with very few glands or bristles on the petiole; the points of the sepals often very leafy. Calyx-tube and fruit, broader than deep, and perfectly smooth, the fruit pendent. Peduncle with fewer and weaker glandular hairs and bristles than usual, and, in extreme cases, quite naked. A common Northumbrian form, and I have seen it also from Argyleshire, Durham, Cumberland, and West Yorkshire. —*Var. pseudo-rubiginosa* (Lejeune). Bracts and veins, deep red. Upper surface of the leaves nearly naked, and the lower only thinly hairy, but conspicuously glandular. West Yorkshire, Settle.

R. tomentosa (Smith).—An arching shrub, 6 or 8, or even 10 feet high, with elongated branches, duller than in the last, and not so glaucous. Prickles, scattered, uniform. Fully developed leaves, 4 to 5 inches long, the upper surface thinly grey-downy all over in the typical form; the lower more so, with often, but not always, a few inconspicuous glands scattered over the surface. Flowers, generally one to three; bright rose-pink, or not unfrequently pure white. Fruit, oval pitcher-shaped, in the typical form, or sometimes turbinate, never pendent, ripening in the north of England through September; furnished with a medium-sized disk, like that of *canina*. This appears to be universally distributed through Britain. I have seen it from Caithness and Sutherland down to Cornwall, and Devonshire, and Sussex, and gathered it myself in the Isle of Wight, and up to 550 yards in the north of England. It is spread over both the north and south of Ireland. The plants called by Dr. Moore, in "Cybele Hibernica," p. 97, *tomentosa* and *scabriuscula*, he has cultivated side by side in the Glasnevin Garden, and found to come true from seed for at least two generations; and yet his *scabriuscula* does not differ from the type nearly as much as the plant just to be described under that name; but is simply a form with white flowers tipped with crimson, and leaves quite as hairy, but rather more glandular beneath than usual. The principal varieties in Britain are the following:—*Var. subglobosa* (Smith). Fruit, quite globose. The leaves, softly grey-downy on both sides, scarcely at all glandular on the petiole or under surface, the serratures often not so compound as in the type. The flowers, in some of the specimens, seven to eight in a cluster, and the prickles stouter and a little curved. Sherard's plant, on which it was founded, was gathered by the Thames-side near Kingston; and I have seen this variety also from the Isle of Wight, Cambridgeshire, Devonshire, Anglesea, Yorkshire, and Northumberland.—*Var. farinosa* (Rau). A small weak variety, with leaves densely grey-downy when young. Petioles, slightly glandular. Serrations, open and copiously compound. Fruit, obovoid, both it and the short peduncle quite destitute of bristles and glandular hairs, and

main sepals only very slightly compound. Gathered in Perthshire, near Blair Athol. This variety and the last are the forms of *tomentosa* most likely to be confounded with *mollissima*.—*Var. scabriuscula* (Smith). The plant intended by Smith under this name differs from the type by having the leaves less hairy; and, consequently, greener and harsher. They are often very nearly naked on the upper surface, when mature, and are hairy principally on the ribs beneath, and scarcely at all glandular. The prickles are straight and slender, and the fruit ovate and usually densely bristly. This is a widely-dispersed variety. Lindley's *var. resinosa* is essentially the same, with deep-coloured flowers, very narrow leaves, and very sharp compound teeth.—*Var. sylvestris* (Woods).—Prickles, stouter than in the type, and slightly curved. The average of the variety, as represented in my fasciculus, differs principally from *scabriuscula* by the leaves being considerably glandular beneath.—*Var. obovata* (Baker). Prickles, uncinat. Leaflets, obovate-oblong, with a sub-deltoid base and very deep and compound upper teeth, grey-green, soon quite naked on the upper surface, thinly hairy and glandular beneath. Durham, by the side of the high-road a little out of Eglestone, going towards Middleton in Teesdale. A connecting link between *tomentosa* and *pulverulenta*.

Group 3.—*Rubiginosæ*.

R. rubiginosa (Linn.).—A bush from 3 to 5 feet high, the main stem scarcely arching, and the branch short and straight. Main prickles, scattered. Well-developed leaves of the barren shoot, $2\frac{1}{2}$ to 3 inches long, with seven leaflets. Flowers, usually one to four; generally full rose, 12 to 15 lines across when expanded. Ripe fruit, sub-globose, measuring about $\frac{1}{2}$ inch each way. The common Sweetbriar of gardens, indigenous amongst the chalk-hills of the south of England, but I have seen specimens from as far north as Perth and Inverness. Messrs. Moore and More do not claim it with any confidence as a native of Ireland.—*Var. permixta* (Déséglise). Leaves in our plant quite without hairs, but as densely glandular on the under surface and petiole as in the type. Styles, quite glabrous. Fruit, oval pitcher-shaped, half as long again as broad, and decidedly narrowed at the neck, densely prickly, the sepals falling before it reddens. Surrey. This recedes from the type towards *micrantha* by the naked styles and shape of the fruit, but in other respects agrees with the type.—*Var. sylvicola* (Déség. et Ripart). Bush, laxer and not so strongly scented as in the type. Prickles, more slender. Leaflets, larger, thinly hairy beneath. Glands, fewer and finer. Fruit, broad oval pitcher-shaped. Styles, hairy. North Yorkshire.

R. micrantha (Smith).—A taller and laxer bush than the last, generally, but not always, without any decided Sweetbriar fragrance. Prickles, scattered and quite uniform. Well-developed leaves, $2\frac{1}{2}$ to 3 inches long, with seven leaflets. Petals, pale rose, the expanded corolla not much over an inch across. Fruit, bright scarlet, oval pitcher-shaped, 7 and 8 lines long by 5 to 6 lines broad, with a decided disk like that of *canina*, changing colour late in September or early in October. This differs from *rubiginosa* by its laxer habit of growth, faint odour, uniform prickles, glabrous styles, and in the character of the fruit and sepals, and may be considered midway between *rubiginosa* and *canina*. In some parts of the Isle of Wight it is as plentiful as *canina*; it is a plant of the Channel Islands; Mr. Borrer gathered it in many places in Sussex, and Mr. Briggs in Devon and Cornwall; and it extends northward to Anglesea, Cheshire, Yorkshire, and to Northumberland. In Ireland it appears to be restricted to the neighbourhood of Cork.—*Var. Briggsii* (Baker). A luxuriant variety, with leaflets 15 to 18 lines long, 10 to 12 lines broad, naked above, less glandular than in the type beneath. Calyx-tube and fruit, shorter and stouter, and, like the peduncle, quite naked. Sepals, more pinnate and scarcely glandular on the back. Devonshire.—*Var. Hystrix* (Leman). A small variety with narrow sharply-toothed leaves, densely glandular beneath, but quite without hairs. Terminal leaflet, cuneate at the base. Peduncle, densely aciculate. Calyx-tube, naked. Surrey, Oxfordshire, and Gloucestershire. In leaves and general habit very like *R. sepium*; but the sepals are glandular on the back, and the peduncle densely bristly.

R. pulverulenta (M. Bieb.).—A taller and stronger bush than *micrantha*, with a similar habit. Prickles uniform, or with a few setaceous bristles intermixed. Well-developed leaves of the barren shoot 3 to $3\frac{1}{2}$ inches long, with seven leaflets. Flowers, usually one to three; pink, 15 to 18 lines across. Fruit, ovate-urceolate, as large as that of *canina*, and with a similar disk, not ripening till October or late in September. This is very near *micrantha*, but is a stronger plant. I have seen it only from four counties in Britain—Somersetshire, Yorkshire, Durham, and Northumberland.—*Var. Billiettii* (Pugot). Prickles of the main stem decidedly unequal, the main ones as large and as strong as those of

the type, but only slightly hooked. Leaflets, smaller. Fruit, ovate-pitcher shaped, 7 to 8 lines deep. In Britain I have seen this only from Allesley, in Warwickshire.—Var. *cryptopoda* (Baker). Prickles, rather unequal, the large ones hooked and robust. Leaflets, ovate-oblong, the terminal one about an inch long by three-quarters as broad; the upper surface glaucous green, naked; the lower thinly glandular all over, hairy on the main veins. Fruit, sub-globose, 7 to 8 lines each way. West Yorkshire.

Group 4.—Caninæ.

Series 1.—*Ecristatæ*. Leaves, not glandular beneath. Fruit, very hard when green, not ripening till October or the latter part of September; the sepals still remaining reflexed after the petals fall, and becoming disarticulated before it changes colour.

Peduncles not bristly; leaves glabrous on both sides.

R. Canina (Linn.)—Var. *Lutetiana* (Leman). An arching bush often 10 or 12 feet high, with elongated arching branches. Prickles, scattered, uniform, falcate, very robust. Fully-developed leaves of the barren shoot, 3 to 4 inches long, with seven leaflets. Flowers, one to four, pinkish, 18 to 24 lines broad. Fruit, ovate pitcher-shaped, 7 to 9 lines long, not changing colour till October in the north, or late in September in the south of England. In the broad sense of the term, as here defined, *R. canina* is universally dispersed through Britain, including Ireland, and is in most districts far more common than any other Rose, or than all the others put together. In the north of England it reaches an altitude of 450 yards. It extends everywhere through Europe, except Lapland and Finland, and reaches the Canaries, Barbary, Persia, and Siberia. Of the varieties here described, *lutetiana*, *dumalis*, and *urbica*, with intermediates between them, are the most common in Britain, all the others being much less frequent. Of this, the names *glaucescens* and *Afzeliana* refer especially to the plant with glaucous leaves. *R. Malmundariensis*, a modification of this variety with sepals glandular on the back, has been gathered by Rev. W. H. Purchas in Derbyshire.—Var. *surculosa* (Woods). A very robust form, like the last, but with flowers often ten to twelve (I have seen twenty to thirty) in a cluster, flat leaflets broadly rounded at the base and with more open teeth; the young shoot and leaves often suffused with red. Apparently confined to the south of England.—Var. *sphærica* (Gren.) Differs from *lutetiana* only by its broader leaflets, more rounded at the base, slightly pubescent petioles, globose fruit 7 to 8 lines broad and deep, and more villose styles. A plant gathered at Modoney, in Devonshire, quite agrees with what I have under this name from Besançon and Geneva.—Var. *senticosa*, (Ach.) Fruit perfectly globular, but much smaller than in the last; the general habit of the plant very slender and flexuous, the fully-developed leaves not more than an inch long by 6 to 7 lines broad; the teeth very acute. "It has the aspect of *R. sepium*, but the petioles and leaflets are glandless."—*Déséglise*. Devonshire.—Var. *dumalis* (Bechst.) Stipules, more densely gland-ciliated than in the type. Teeth of the leaves, more or less compound, with the secondary serrations gland-tipped. Petiole, more or less covered with glandular hairs, and often a little hairy. Sepals also gland-ciliated, and the flowers sometimes deeper in colour. A very common form, also either green or glaucous; the latter *venosa* (Sw.), and *glaucophylla* (Winch). Specimens gathered in Northumberland and Leicestershire, with sepals glandular on the back; and a plant in Durham, near Darlington, exactly accords with *R. Malmundariensis*, (*Déség.*), with round fruit and numerous flowers in a cluster.—Var. *biserrata* (Mérat) (*R. vinacea*—Baker). Scarcely different from the last, but the serratures open and very compound, the petioles more covered with glandular hairs, and the glands extending a little to the mid-rib beneath. *Déséglise's* plant has globose fruit; my *vinacea* has oblong fruit, narrow sharp-pointed leaves and bracts, branches and stipules suffused with vinous red.

Peduncles not bristly; leaves naked above, hairy only on the ribs beneath.

Var. *urbica* (Leman). General habit, leaves, and fruit of *lutetiana*; but the grey or green, simply toothed-leaves are thinly hairy on the under surface. Serration, sharp and simple. Petiole, densely pubescent, but scarcely at all glanduloso-setose. Fruit, oblong or ovate pitcher-shaped, rarely sub-globose. A very common variety, from which *R. platyphylla* only differs by its larger grey-green leaves more rounded at the base, and large sub-globose fruit.—Var. *frondosa* (Steven) differs from the last by its small flat ovate-oblong leaflets much rounded at the base, and small subglobose fruit. Yorkshire, Sussex, and Isle of Wight. Very near *obtusifolia* (Desv.) (*R. leucantha*—Bast.), but the leaflets are naked above and less hairy below.—Var. *arvatica* (Baker) bears much the same relation to *urbica* that *dumalis* does to *lutetiana*. Leaflets, obvate-oblong, naked above, hairy on the ribs below. Serratures, copiously compound. Accessory teeth, gland-tipped. Petioles, densely

pubescent, covered with glandular hairs, and the glands often extending to the mid-rib beneath. Bracts, stipules, and sepals, copiously gland-ciliated. Fruit, ovate. A common form in the north of England. I have gathered it in North Yorkshire with sepals glandular on the back.

Peduncles not bristly. Leaflets more or less hairy on both sides.

Var. *dumetorum* (Thuill.) Leaflets, grey-green, softer in texture than in the foregoing forms, and sooner destroyed by frost. Flowers, often deeper in colour than the preceding. Fruit, large, generally ovate-urceolate, not so hard when green, and ripening earlier than in the foregoing varieties, and the sepals often not fully reflexed. Principally in the north of England.—Var. *pruinosa* (Baker). Like the last, but very glaucous, the serrations laxer and compound, the secondary teeth gland-tipped, and petioles slightly glandular. Northumberland, Durham, and Yorkshire amongst the hills. A similar plant has been gathered in Derry by Dr. Moore.—Var. *incana* (Woods). Leaflets, of average size, narrowly ovate-oblong, very glaucous, and slightly downy above, densely downy and with a few inconspicuous scattered glands beneath. Serration, copiously compound, the secondary teeth gland-tipped. Petiole, both pubescent and setose. Peduncle, slightly hairy. Styles, densely villose. Fruit, large and oblong. Sepals, not falling so soon as usual. Gathered in Forfarshire by G. Don.—*R. canescens* (Baker) is a form with similar leaves, but with the fruit and sepals of the type.—Var. *tomentella* (Leman). Branches, green and very flexuous. Prickles, very strongly hooked. Fully-developed leaflets, under an inch long, ovate-oblong, rounded at the base, green and thinly hairy above, hairy all over, and sometimes with a few inconspicuous glands beneath. Flowers, small and very pale. Fruit, small ($\frac{1}{2}$ to $\frac{5}{8}$ -inch long), sub-globose or broad-ovate pitcher-shaped; very late in ripening. I have gathered this in many parts of England, from the Isle of Wight northward to Northumberland, and received it from nearly all my correspondents; and yet it does not seem to have been known to either Woods or Borrer. *Déséglise*, Grenier, and Reuter all classify it with the *Rubiginosæ*; but the glands beneath are so few and faint as to be scarcely visible except with a lens. For a full account of its modifications, see a paper by Crepin in the "Bulletin of the Royal Botanical Society of Belgium," v. p. 26.

Peduncles more or less bristly, and covered with glandular hairs.

Var. *Andevagensis* (Bast.). Differs from *lutetiana* only by its aciculate peduncles. Not unfrequent, especially in the south of England. A form with sepals glandular on the back, from the Pass of Lanrick, Perthshire, Braemar, and Carnarvonshire.—Var. *verticillacantha* (Mérat). Bears the same relation to *dumalis* that the last does to *lutetiana*. Not uncommon.—Var. *collina* (Jacq.). The representative of *urbica* in this group. As gathered by Mr. Borrer in Surrey, and Mr. Briggs near Plymouth, this has numerous flowers in a cluster, and flat leaves broadly rounded at the base with moderately open serrations; but the commoner form is, like ordinary *urbica*, less robust, with narrower more sharply-toothed leaves.—Var. *cæsia* (Smith). Very near the last, the leaves grey-green, softly hairy beneath and slightly so on the upper surface, the teeth slightly compound. Gathered in Derbyshire, Leicestershire, and Northumberland.—Var. *concinna* (Baker). Prickles, very much hooked. Leaflets, very small, the terminal one 8 to 9 lines long, flat, broad, obovate, thinly downy above when young, hairy all over beneath. Devonshire.—Var. *decipiens* (Dumort.). Like *tomentella*, but the peduncle densely bristly; the mid-rib beneath more glandular. Petiole both pubescent and covered with glandular hairs, with several unequal bristles. Sepals, not fully reflexed and densely glandulous on the back. Northumberland.

Series 2.—*Sub-cristatæ*. Leaves, not glandular beneath. Fruit, softer when green, in the north of England ripening early in September. Sepals ascending after the petals fall, and not disarticulated till after it turns crimson. Disk, narrower than in the last section. Styles, more densely villose.—Var. *Reuteri* (Godet). Prickles more slender than in the plants of the last series. Habit, leaves, armature, and tothing like that of *lutetiana*, but the peduncles shorter and almost or quite hidden by the large clasping bracts, the flowers often deeper in colour, and sepals and fruit of the character just indicated. Leaves and calyx-tube, glaucous. Bracts, stipules, and branches in exposure suffused with red. Fruit, moderate or large-sized, ovate-oblong or sub-globose. Sepals, often (but not always) glandular on the back. This appears to be widely diffused through the hilly tracts of the north of England.—Var. *subcristata* (Baker). Bears just the same relation to *dumalis* that the last does to *lutetiana*. It is not unfrequent through the hilly tracts of the north of England; and Mr. Watson gathered it in Perthshire. A plant like this, but with deep red flowers and bristly peduncles, by the Swale-side, near Keld.—Var. *Hailstoni* (Baker). Prickles, moderately close and numerous, the large ones thickened and falcate, but passing down rather abruptly into numerous stout straight

unequal bristles. Leaves like those of the last form, but the fruit not ripening so early, and the sepals becoming sooner disarticulated, and styles not so densely villose. North Yorkshire. In the irregularity of its prickles, this approaches *hibernica*.—Var. *implexa* (Gren.). Leaves and general habit of *urbica*, with the fruit of this series. Seen only from the neighbourhood of Richmond in Yorkshire.—Var. *coriifolia* (Fries). Combines the general habit of *dumetorum* with the fruit and sepals of this series. Leaflets, greyish-green, and thinly hairy above, paler and softly hairy beneath; the terminal one ovate-oblong, rounded at the base; the serrations simple, blunt, open. Fruit, large and generally round. In Britain apparently rare and confined to the hilly tracts of the northern half of the island. I have seen it from Aberdeenshire, Perthshire, Berwickshire, Northumberland, Lake, Lancashire, and have gathered it myself in North Yorkshire.—Var. *Watsoni* (Baker). Differs from *coriifolia* by its double-toothed leaves, often not so hairy above. Secondary teeth, gland-tipped. Stipules and bracts, not so large, and densely gland-ciliated. Petiole, covered with glandular hairs as well as villose. Stipules and bracts, not so large, and nearly or quite glabrous on the back. Inverness, Perthshire, Northumberland, Durham, Cumberland, and Westmoreland.—Var. *celerata* (Baker). Habit and leaves of *tomentella*, with the fruit and sepals of this section. Seen only in Holywell dene, Northumberland.

Series 3.—Sub-rubiginosæ. Leaves, glandular on the mid-rib, and slightly so on the principal veins; but not over the surface, as in the true *Rubiginosæ*.—Var. *Borreri* (Woods). Prickles, robust and strongly hooked. Leaflets, flat, the terminal one 15 to 18 lines long, broadly rounded or even cordate at the base. Flowers, often numerous in a cluster; the peduncle weakly bristly; the calyx-tube ovate pitcher shaped, generally naked. Sepals, copiously compound, naked on the back, reflexed or spreading after the petals fall, disarticulated by the time that it changes colour. Styles, thinly hairy. This is a plant which has been more misunderstood than any other British form, and which occupies just that intermediate position between ordinary *canina* and three or four of the others, that varieties of the former are liable to be assigned to it by those who have only book descriptions to guide them. The true plant is clearly in its right place in the *canina* group, and is, on the whole, nearer to *tomentella* than to any other variety. I have seen it from Kent, Sussex, Surrey, Middlesex, Hertfordshire, Shropshire, Worcestershire, and Yorkshire.—Var. *Bakeri* (Déséglise). Prickles, more slender and less hooked than in the last. Leaflets, obovate, full green, copiously doubly serrated, the base cuneate, entire, the upper surface naked when mature, the lower thinly hairy, plainly glandular on the mid-rib and main veins. Flowers, never more than three to four in a cluster. Peduncles, very short, naked or weakly bristly. Fruit, naked, oblong or turbinate, ripening early in September. North Yorkshire, hedges at Sowerby, near Thirsk. The variety of *canina* that comes nearest to *pulverulenta*.—Var. *marginata* (Wallr.). Prickles, considerably more slender and less hooked than in ordinary *canina*. Branches, dark purple and glaucous in exposure. Leaves, oblong, glaucous-green above, very pale beneath, and the veins unusually prominent. Flowers, not more than three or four together. Peduncles, faintly bristly. Fruit, obovate or sub-globose, ripening early in September. North Yorkshire, near Thirsk; and similar plants, but with the petiole slightly hairy, gathered in Derry, in the Isle of Arran, and in Carnarvonshire.

Sub-Group.—*Systylæ*.

R. stylosa (Desv.) var. *systyla* (Bast.).—A bush, 8 to 12 feet high, with elongated arching branches. Prickles, uniform, scattered, the base deltoid, with shorter and less-hooked points than in *canina*. Leaves of the barren shoot, $3\frac{1}{2}$ to 4 inches long, with seven leaflets. Flowers, generally three to six in a cluster, pale pink or rarely white, 15 to 18 lines across when fully expanded. Fruit, broad ovate-urceolate, or sub-globose, $\frac{1}{2}$ to $\frac{5}{8}$ inch long by $\frac{3}{8}$ to $\frac{1}{2}$ inch broad, not ripening till October, the sepals falling before it changes colour. Column of styles, glabrous, generally protruded 1 to $1\frac{1}{2}$ lines beyond the very prominent disk. This is easy to recognise from *R. canina* in the typical form, but is quite connected with it by intermediate gradations. I have seen a form in which the column of the styles was protruded in the central flowers of a cluster, but not in the outer ones, and other specimens with the styles not at all protruded, for the rest quite doubtful between this and *collina*. I have seen this variety from Kent, Sussex, the Isle of Wight, Middlesex, Hertfordshire, Gloucestershire, Somersetshire, and Devonshire.—Var. *Desvauxii* (Baker). Column of styles, protruded as in the last, from which it only differs by its pure white flowers, leaves thinly hairy all over beneath, and more hairy petioles. A plant coinciding with the specimens in Déséglise's fasciculus, gathered by Mr. Borrer at Hartwell, in Sussex.—Var. *opaca* (Baker). Leaves, dull grey-green above, and still more hairy beneath than in the last, quite three-quarters

as broad as long, and rounded at the base. The peduncle shorter and quite naked, the flower pure white, and not much over an inch across, scarcely more than the head of stigmas protruded. Kent, between Chilgrove and Brooms.—Var. *gallicoides* (Baker). General habit and leaves in shape like those of *systyla*, but the prickles of the branches copiously intermixed with bristles and glandular hairs; the leaves only very faintly hairy beneath, and the corolla pure white; the fruit obovoid, naked, $\frac{3}{8}$ inch long by $\frac{3}{8}$ inch broad. Warwickshire, Chesterton Wood, near Myton. A very remarkable variety; and I have nothing from the Continent resembling it. In armature it recalls the *Gallicanæ*, only that it is more densely aciculate and setigerous than any of the plants of that section I have seen.—Var. *Monsoniæ* (Lindl.). A low erect bush, with short ascending branches, with a few glandular hairs, and mixed bristles amongst the prickles. Leaflets, in shape and serration just like those of the type, greyish-green, naked above, thinly hairy beneath. Peduncles and sepals of the type, but the petals of a "beautiful glowing red," and larger than in any British Rose. Fruit, roundish and orange-red, like that of *gallica* in size and shape. A single bush, found by Miss Monro, in a hedge near Watford, in Hertfordshire, and transferred to the garden of Lady Monson, from which it was spread in cultivation. Mr. Borrer suggests that it is a hybrid with one of the *Gallicanæ*.

R. arvensis (Huds.).—Bush, not more than 2 or 3 feet high when not supported, with long trailing shoots, which are purple and glaucous in exposure. Prickles, scattered, uniform, strongly hooked, the lower part sub-deltoid. Leaves of the barren shoots $2\frac{1}{2}$ to 3 inches long, with seven leaflets, both sides quite naked, the upper deep green, the lower sub-glaucous. Flowers, four to six, if the branch is at all robust. Calyx-tube turbinate, purple and glaucous, usually naked, rarely a little glandular. Corolla, 15 to 18 lines across when expanded, pure white, with a yellow throat. Fruit, sub-globose, naked, measuring about half an inch long and thick, not turning red till October, with a thick prominent disk. This is much more common in the southern than the northern half of England; and though it reaches Kincardineshire, it is a very rare plant north of the Tweed. Our ordinary plant is the *repens* of Déséglise; his *arvensis* is a weak form, with the peduncle naked and flowers usually solitary.—Var. *bibracteata* (Bastard). Shoots, stronger and more assurgent than in the type. Leaflets, 15 to 18 lines long by two-thirds as broad, more pointed than in the type, and more sharply toothed. Calyx-tube and fruit, obovoid. Sepals, a little more compound. Peduncles, rather more spreading than in the type, thinly glandular. Petals, often an inch deep. Fruit, $\frac{5}{8}$ to $\frac{3}{4}$ inch long by $\frac{1}{2}$ inch broad. Seen from Sussex, Devonshire, Cambridgeshire, Essex, and Northumberland. Liable to be called *systyla* by those who know ordinary *arvensis* and not the other species.

From the preceding list, *rubella* and *pomifera* require to be deducted as doubtful natives. In addition, a few other species have been gathered as strays from garden cultivation. *R. cinnamomea* (L.), found by Mr. Sabine, long ago, near Pontefract, is frequent in gardens, and widely dispersed as a native plant in Continental Europe. *R. lucida* (Ehrh.) found by Mr. Borrer near Keswick (Phyt. ii. p. 437), and by Mr. Reeves near Tunbridge Wells, is a common North American Rose, also frequent in gardens. The same plant has been gathered in a sub-spontaneous state in France and Germany, and is *R. baltica* (Roth. and Koch.). The sub-spontaneous Yorkshire and Sussex Roses, mentioned by Mr. Borrer in the "British Flora," 3rd edit. p. 245, do not appear to be essentially different from *R. provincialis* (Ait.); and the *R. arvensis*, var. *Andersoni*, mentioned by Smith, "Eng. Flora," ii. p. 398, I believe to be *R. austriaca* (Crantz.). The two latter are both members of the *Gallicanæ* group.

The preceding article is an abstract of an exhaustive paper by Mr. J. G. Baker, published in the *Journal of the Linnean Society*.

Dead Ash Trees.—In the district from Lewisham to Beckenham, Kent, during the last four or five years, there has been an extraordinary number of deaths amongst Ash trees. This failure has not been confined to any particular age of tree, for many of them would measure at least 16 inches in diameter a yard from the ground, whilst others are only a few years old; but, principally, the older ones have suffered the most. There are, at the present time, numbers to be seen standing quite dead; whilst others are reduced almost to skeletons, and cannot last more than one or two seasons. Why this should be in the valley of the Ravensbourne some of your readers may, perhaps, be able to give a satisfactory reason. The cause, whatever it may be, appears to confine itself to the Ash, for all other trees are in a healthy condition. The late May frosts have made the Ashes all look very queer; and many that might have shown some life for a short time longer will, no doubt, be brought to an untimely end.—C. J. Cox, Catford Bridge.

ANCIENT ASIATIC GARDENS.

THE pleasure-gardens of the ancient Asiatics in no way resembled either the flower-gardens or landscape-gardens of our own day. They were not established for mere beauty's sake; indeed, flower-gardening, as we understand the matter, was comparatively unknown. Roses, Violets, and a few other flowers were, it is true, cultivated for the purpose of garland-making, and also for the decoration of banquets. Such flowers as those alluded to, were grown in close juxtaposition with succulent edible vegetables; and Plutarch naïvely informs us that in Greek (so called) gardens the Roses and Violets looked all the prettier for being grown side by side with the Leeks and Onions. In the Roman hortus or garden the chief object was, as, doubtless, in oriental enclosures of similar character, to produce such vegetable supplies, either decorative or edible, as were required for ordinary family use, or public occasions, there being no thought of making such gardens ornamental, any more than mere beauty is sought in the modern Rose gardens of Persia (which frequently

deceivers of those public and private groves of the Greeks. In our illustration, which represents an ancient Assyrian garden, it will be seen that the character of the architecture of an Assyrian palace, as far as we are able to judge of it by the interesting discoveries of Layard, Botta, Smith, and others, has been kept sufficiently in view. There is the statue-lined gateway, usually bearing the cuneiform inscriptions which form the mural literature of Assyrian palaces; and there are, also, the great terraces, one over another, on which the foliage is raised far above the level of the surrounding plain; a circumstance which some have imagined may have given rise to the term of "hanging gardens," which an ancient writer has made use of in special allusion to the gardens of Babylon. I have sometimes thought that the Weeping Willow (only recently known to Europe), which was indigenous, from the earliest recorded times, on the banks of the Euphrates, may have assisted in making this term more appropriate, as its slender branchlets, hanging in streaming and delicate verdure

An Ancient Assyrian Garden.

contain many hundreds of acres) where thousands of Rose trees are grown, not for ornament, but for the manufacture of the famous attar; such gardens being manifestly intended to be simply useful and profitable. It was not the garden that formed the pleasure-ground of ancient nations. The true pleasure-ground consisted in groves of trees, and what the Romans termed a viridarium, or "place of greenery," which was the delight of both Greek and Roman, their public and sacred groves being planted with the greatest care; and this was, doubtless, the case also with the Asiatics who had preceded them. Recent travellers describe the importance attached to groups of trees in regions where vast arid plains occur; telling us that caravans endeavour to arrange their times of travel in such a way that two sets of travellers may not arrive together at the few-and-far-between small groves of trees, which would not afford a sufficient supply of the all-important desideratum of shade for more than a single party, during a brief period of rest. It was, therefore, the supply of shade that probably suggested the first artificial plantations of trees; and we think we may safely state that such plantations were the pre-

over the parapets of such terraces, must have imparted a drooping effect of singular beauty, which one may easily imagine led to the coinage of a name descriptive of its peculiar character.

H. N. H.

Steppe Vegetation.—Just as in the tropics all varieties of vegetation generally show a tendency to assume the nature of trees, so in Asia's temperate zone some steppes are characterised by the extraordinary height to which the flowering herbs grow. When driving in the low Tartar springless waggons through the trackless paths of these herbage plains, it is necessary to stand erect to discover the right course, for, otherwise, the view is intercepted by the high stems of the herbs, which here grow so densely as almost to resemble a wood, and, as the waggon rolls on, these lofty stems bow down beneath the wheels. Some of these Asiatic steppes are plains of Grass-land; some are covered with Salt-wort—a succulent, evergreen, and articulate plant—and others are overspread with far-glistening salt, which, sprouting forth like Lichens, besprinkles unevenly, as fresh-fallen snow, the clayey soil.

WORK FOR THE WEEK.

Flower Garden and Pleasure Ground.

WHERE the planting out of bedding plants is quite finished, which will generally now be the case, little will require to be done for some time except attending to routine operations, such as mowing, cleaning, and the staking and tying up the various sorts of plants which require that attention, and the pegging down of Verbenas, Petunias, and plants of similar growth. Copious waterings should, for some time to come, be given to the flower beds and borders whenever the state of the weather renders that attention necessary. Regulate the growth of climbing Roses, Clematises, Tropæolums, and other plants trained to pillars, ornamental wire arches, and similar devices; and, wherever the embroidered or carpet style of bedding is attempted, this must have unremitting attention in the way of regulating the different sorts of plants employed, an operation which involves stopping and pinching back throughout the greater part of the season. Carpet bedding, as a rule, should be effected without the aid of flowering plants. It should, in fact, be confined to plants possessing remarkable foliage, and of this class there is a considerable variety suitable for the purpose, hardy as well as tender, such as *Ajuga*, *Antennaria*, *Echeveria*, *Semprevivum*, *Saxifraga*, *Veronica*, *Sedum*, *Cerastium*, *Cineraria*, &c., most of which are indigenous to Britain or the South of Europe, and perfectly hardy; together with the highly-coloured tender species from Brazil and Peru, &c., such as the *Alternanthera*, *Coleus*, *Iresine*, &c.; and lastly, but by no means the least useful, is the Golden Feather *Pyrethrum*, now so well known and so extensively used for this and other purposes, such as marginal lines to beds and borders. Keep lawns, Grass walks, and belts free from Plantains, and other broad-leaved plants; and attend to the staking up of all tall-growing herbaceous plants before they become bent or broken down. *Deutzias*, *Lilacs*, *Guelder Rose*, and various other deciduous flowering shrubs, will soon be out of bloom, and may be cut back to any necessary extent; while straggling branches of *Laurel* and other evergreens may now also be cut back. Hedges of *Holly*, *Privet*, and *Box* may now be clipped; and by the constant practice of mowing, sweeping, weeding, and rolling, &c., continue to maintain neatness, and high keeping everywhere, both in the pleasure grounds and flower gardens.—P. GRIEVE, *Culford Gardens*.

Greenhouses and Stoves.

Acacias, *Rhododendrons*, *Heaths*, and other hard-wooded plants, will now be contributing to the beauty of indoor structures. Any appearance of mildew on *Heaths* should be immediately checked by dusting with sulphur; in the centre of large plants mildew often develops itself unnoticed, a circumstance which renders it necessary to keep the shoots in that portion of the plant thin; such prunings may be used for propagating purposes. To *Fuchsias*, one stake only should be placed as a support, the lateral branches being allowed to hang gracefully down. In stoves, a genial moist temperature should be maintained; the syringe should be freely used amongst growing plants, and fumigating frequently practised, in order to keep down insects. *Zamias* and *Palms* making young leaves should never be allowed to receive a check from cold draughts or be in want of water. Creepers should be pruned, trained, and luxuriant growths stopped in order to induce them to form good specimens. *Alocasias* and *Marantas* may be kept above water tanks to encourage their growth. Ferns will now enjoy a steady moist temperature and plenty of shade. Sprinklings from the syringe should be occasionally given; but care must be taken to keep the foliage of *Gymnogrammas* and *Adiantums* always dry. Pits and frames, now mostly cleared of bedding plants, may be filled with *Pelargoniums* for late flowering, and other plants. *Verbenas* may be increased in gentle heat, to take the place of early annuals, or other plants that are likely soon to be done blooming. Seed of *Cinerarias* should be sown immediately it ripens, either in gentle heat or in cold frames. Shift *Chrysanthemums* as they require it, and liberally supply them with water. *Heartsease* may be increased from cuttings in frames with a north aspect. *Balsams* and *Cockscombs* should be shifted as they require it, never allowing them to become pot-bound; if a little bottom-heat is given, and at the same time some top air, it greatly improves them.—M.

Orchids.

Syringe freely at least twice a day, viz., morning and evening; and give a full supply of air, especially during close sultry weather. Soft or rain-water is best, and every Orchid-house should be provided with a tank sufficiently large to collect a supply; and, if a hot-water pipe is passed through it, so much the better. Most Orchids require a copious supply of water at the roots when growing, and there are some that can never be allowed to get thoroughly dry without injury. Some species, especially *Indian Dendrobies* and *Mexican Lælias*, on the

other hand, require a season of rest more or less decided. In practice, we find all those Orchids without pseudo-bulbs are incapable of living, for any great length of time, without moisture. To this class belong *Cypripediums*, *Disas*, *Phalænopsis*, and other plants of a similar character; while, on the other hand, all pseudo-bulbous Orchids are more or less inclined to rest at some season of the year. Good drainage is, of course, presupposed, and then it is nearly impossible to over-water, especially if the compost is in a fresh porous condition. Carefully shade from bright sunshine; and keep a sharp look out for insects, especially thrips, as these soon do a deal of damage among *Aërides*, *Vandas*, *Saccolabiums*, and *Cypripediums* during the summer months. Among plants in flower we may notice *Vanda limbata*, *V. tricolor*, *V. suavis*, and others; *Aërides Fieldingii*, and the equally beautiful dwarf-habited *A. affine roseum*. Many *Dendrobiums* are now at their best; and those on blocks should be plunged overhead in tepid water regularly, so as to moisten the roots and moss thoroughly. In some cases this should be done once, or even twice, daily.—F. W. BURBIDGE.

Hardy Fruit.

Strawberries should now have copious waterings with house sewage, sufficient to penetrate the entire mass of roots and soil. Drought is one of the greatest enemies of this crop. I have known experienced growers of forced Strawberries to throw out any pots that had once got so dry that the leaves fell over their sides. Such plants they declared would turn out not to be worth keeping; the fruit, if it swelled, would be comparatively flavourless; and the chances were, that before the fruit had ripened, the entire plant would fall a prey to red spider. Like conditions bring about like results; and out-of-doors dryness is almost as disastrous as within; from the moment plants show flower till the fruit is finished, they should never once be dry. The drain upon them to finish a fine crop is very great; and, therefore, water and food must be plentifully provided; both should also be husbanded, as well as given plentifully. To this end the surface should be mulched with long dung, short Grass, spent tan, or covered with tiles. These appliances serve several purposes; some of them feed the plants with food, all of them help to hinder the food and moisture within the earth from being dissipated, and furnish a more or less clean bed for the ripe fruit. They are, also, an antidote for earth splashings which destroy Strawberries. Strawberry tiles are, perhaps, the cleanest bed; but they have two greivous draw-backs—they are expensive and become too hot, so that the fruit sometimes gets almost baked upon them. Short Grass rots too soon, harbours slugs and snails, and, should wet weather prevail for a week, gives the fruit a musty flavour, and hastens its decomposition. Upon the whole, there are few things better than long stable litter, applied early, so as to have all the ammonia washed out of it before the fruit is ripe. Clean straw and dry Fern leaves form a soft cushion for the fruit and keep the moisture in the soil. Net Strawberries the moment they begin to change colour. Keep the net, say, a yard above the fruit. It will take a little more net to cover the sides, but then the net will last as long again as when lying on the wet leaves or earth. It will, also, keep the birds out more effectually; and the gatherer can go in under without tearing the net off for each dish of Strawberries wanted. Late crops, such as *Myatt's Eliza* and the old *Elton Pine*, will hardly need netting up until the main crops are gathered, if planted on north borders. The more entirely these crops can be grown away from sun, the better their quality and the later the crop. It is not yet too late to make new plantations of Strawberries from the latest of the forced plants. Trench a piece of ground a yard deep; enrich it 6 inches thick with the best manure at command, and plant out *President*, *British Queen*, or *Napier Strawberries* in rows a yard apart, and 2 feet from plant to plant. Keep clean throughout the summer, and gather about a peck from a plant next season. Early forced plants, such as *Black Prince* and *Keen's Seedling*, planted out in March, will yield a second good crop this autumn. Here is another Strawberry hint worth knowing—remove *Black Prince* behind a north wall; after yielding a crop in March, leave them in the pots; remove all blooms that show till the end of August; then top-dress the plants; place them in a cold pit, and gather ripe Strawberries through September and even October.—D. T. FISH.

Kitchen Garden.

Whenever a crop is done with, manure and dig the land on which it grew, in order to have it in readiness for something else. Nothing impoverishes ground so much, or looks more untidy, than runaway vegetables. In some soils it may be beneficial to dig in the remains of green crops, I have, however, given up the plan believing it to conduce more to clean culture to have all garden refuse either taken to the pigs or placed out of sight, in a heap, to ferment; decomposition in the latter case being assisted by slight dressings of salt and lime. In this way a very large heap of valuable manure soon accu-

mulates. Peas in windy places are, sometimes, apt to partially escape from the sticks which support them; when this tendency is first noticed, if a strand of rope yarn is run along the rows on the lee-side and linked here and there to the sticks, it will turn them back in the right direction, and prevent them from being broken down. Where Peas are not already mulched, if they exhibit the ast symptoms of distress from heat or drought, mulch immediately with manure, Grass, or anything that is available; one good watering will than place them in a position to perfect their crop. As a rule, it is not advisable to sow late Marrow Peas after the middle of this month. Here, as Marrow Peas are in demand throughout the season, I usually make the last sowing about the 20th. Last year we planted Veitch's Perfection and Ne Plus Ultra on the 26th, and we gathered from them till far into October, but the season was very favourable, and the result may not always be so satisfactory. Nevertheless, in all parts of the country, if the land has been deeply worked and well manured, late Marrow Peas may be sown with a fair chance of success in the middle of June. Sow Turnips to succeed those just up; burnt earth, or ashes from any substance, except coal, has an invigorating influence upon the growth of Turnips in dry weather. The Red American Stone and Orange Jelly are the best Turnips for sowing at this season. Avoid, if possible, the necessity for sowing in freshly-dug land. If the land has been prepared a week or so, the moisture, even in dry weather, will have risen by what is termed capillary attraction, and, by drawing the drills rather deeper than necessary or desirable early in the spring, the seeds may be laid in moist soil, and germination thereby assisted. Continue planting, as opportunity offers and space becomes vacant, such crops as Brussels Sprouts and early Broccoli; provided the land is in good condition, it can scarcely be too firm for Broccoli. Late Broccoli may be pricked out to gather strength before being finally planted out. Make a further small sowing of early Horn Carrots, there is a frequent demand for small young Carrots, which it is always best to anticipate. Sow Spinach once a fortnight in cool damp-bottomed land that has been deeply worked; in dry weather it is sometimes a disappointing crop. We have now an excellent bed of Round Summer Spinach just coming in; it is growing on a piece of land that had in the winter been turned over very deeply for the purpose of eradicating Horseradish. Every season's experience convinces me that the deeper the soil is stirred, the better and more reliable are the crops, and the less are they affected by either wet or dry seasons. The White Silesian or Spinach Beet, is a good substitute for the true Spinach; sown in April or May, or it may be sown now; its young succulent leaves are, in my opinion, at least equal to New Zealand Spinach, and it may always be relied upon to produce an almost unlimited supply. Plant Scarlet Runners in trenches (as recommended for Peas) for a late crop. Earth up and stake those now requiring it. Sow Dwarf French Beans once a fortnight; Windsor or Longpod may be planted for a late crop, selecting a cool moist spot, but not under trees. Topping those now in flower will hasten their maturity, and the same remark is equally applicable to Peas. Keep a watchful eye upon kitchen garden paths, Box edgings, &c., and do not allow weeds to establish themselves nor their seeds to be scattered abroad, to cause double labour in the future. Fire-heat must still be employed in Cucumber-houses, and moisture, both at the roots and in the atmosphere, must be supplied in abundance, especially in hot weather. Only shade as much as will prevent severe flagging.—E. HOBDAV.

In the time of Tulips.—A sufficiently amusing account of a Tulip garden is given in the *Tatler* (No. 218) by a gentleman who overheard its owner and his friends "in very earnest discourse," and thus records his bewilderment at their conversation:—"My curiosity was raised when I heard the names of Alexander the Great and Artaxerxes; and, as their talk seemed to run on ancient heroes, I concluded there could not be any secret in it; for which reason I thought I might very fairly listen to what they said. After several parallels between great men—which appeared to me altogether groundless and chimerical—I was surprised to hear one say that he valued the Black Prince more than the Duke of Vendosme. How the Duke of Vendosme should become a rival of the Black Prince I could not conceive; and was more startled when I heard a second affirm with great vehemence that, if the Emperor of Germany was not going off, he should like him better than either of them. He added, that though the season was so changeable, the Duke of Marlborough was in blooming beauty. I was wondering to myself from whence they had received this odd intelligence, especially when I heard them mention the names of several other great generals, as the Prince of Hesse and the King of Sweden, who, they said, were both running away. To which they added, what I entirely agreed with them in, that the Crown of France was very weak, but that the Marshall Villars still kept his colours."

SOILS AND FERTILISERS.

SOILS SUITABLE FOR PLANT-POTTING AND OTHER PURPOSES.

A WRITER on horticultural matters once asserted that a tolerably correct estimate of the professional character of a gardener might be formed by a careful inspection of his soil-yard, a statement in which there is doubtless some truth; but, at the same time, it should be remembered that necessity, quite as much as choice, may have had something to do with the formation or the selection of soils, and the kinds most required may not be always at his command. Owners of estates and of extensive garden establishments are often alarmed by a modest request from their gardeners to be allowed to take the top spit from a few square yards of some out-of-the-way pasture or piece of meadow land; and the refusal of this reasonable request frequently places the gardener in a position similar to that of the Israelites in Egypt, when compelled to render up their tale of bricks without a supply of straw; or, even worse, as they (the Israelites) were allowed to roam in search of stubble. But, should the luckless gardener venture to roam on his employer's estate in quest of suitable soils for his plants, he would stand a considerable chance of getting reproved by the bailiff, or pounced upon by the keeper, and it would be of small avail for him to attempt to conciliate either of these functionaries by an assurance that some particular soil was indispensable to the welfare of his plants. It may, however, be worth while to direct the attention of owners of gardens to this circumstance, and to respectfully assure them that a reasonable and necessary supply of suitable soil, which, in most instances, is to be found on some part of their properties, is of the greatest importance as regards furnishing a supply of forced fruits, flowers, and vegetables. While the injury inflicted upon a very small portion of their land by the abstraction of the same, is so infinitesimal as to be hardly worth being mentioned. The portion of land from which the 2 or 3 inches in depth of surface soil has been taken can be easily forked or dug over; a handful of grass seeds may be sown upon it, and afterwards well rolled down, and protected from stock by a few hurdles until the young Grass is established, and the injury inflicted may be said to be remedied.

Turfy Loam.

This being rich in decomposing vegetable fibre, forms a soil acceptable to almost all families of plants, forming, as it were, the staple or ground work to which other soils or ingredients may be added. Some cultivators prefer using turfy loam as soon as it is taken from the field or pasture, to form the principal ingredient in the formation of Vine borders, and for Melon culture, &c., justly considering that much of its useful properties are wasted, by its retention of, perhaps, years in the soil-yard, before it is supplied to growing plants. It is obvious, however, that it would be inconvenient for the cultivator to have to repair to the field or pasture, supposing that he had permission to do so, whenever he might require even a small portion of this soil; and most plant-growers will only be too glad to take an opportunity, when it offers itself, to lay in a stock of this soil to last them for several years. When this is carted into the soil-yard, it should be stacked up in the form of a ridge, and might, with advantage, be thatched with some littery material, so as to prevent it from becoming saturated with cold rains during winter, or from being desiccated during dry summer weather. If a portion of good farm-yard manure can be procured simultaneously with this soil, a layer of the same might be made to alternate with a layer of the loam, and this would form a most useful compost for many purposes; as, when it had laid some six or more months, it would then be found to be in excellent condition, without further additions, to use for the potting of fruit trees of various sorts, Strawberries, Roses, and other kinds of plants requiring a rich and somewhat tenacious soil; while, to render it suitable for other varieties of plants, river or silver-sand, leaf-mould, peat, &c., could be added in the proportions required.

Peat, Leaf-mould, and other Materials.

In establishments where collections of Heaths and other hard-wooded plants are cultivated, "fibry peat" soil is indispensable; and, in many parts of the country peat, of the desired quality, is exceedingly difficult to procure. The black bog soil, which is sometimes substituted for it, is absolutely worthless, and any attempt to cultivate hard-wooded plants in such material will be sure to end in failure. Where good peat cannot be found, it is always advisable to purchase it from nurserymen or others who may be in a position to supply it, and this can always be done for a trifling outlay. The best description of peat generally contains more or less silver-sand; but, if found to be in any degree deficient in this respect, sand can then be added to any desirable extent; and, as regards silver-sand of the best quality, there are only a few places in which it is to be found. It can, however, always be purchased, and is not expensive; while, for many purposes, sharp river sand, where it can be obtained, forms a good substitute. Leaf-mould, or soil composed entirely of decayed tree leaves, is also an essential material in every garden establishment; and, generally speaking, there is little excuse for a gardener not having an abundant stock of this always on hand. It is seldom, however, in good condition for potting purposes until it is two or three years old, and, even then, it should seldom or never be used alone, but mixed with loam or other soils. The leaves of the Oak and the Elm are generally preferred to those of the Ash, Horse-chestnut, Walnut, and others, whose leaves are of a softer tissue. Every soil-yard ought, also, to contain a portion of clay, or the runnings of a clay pit; this improves with keeping, and is exceedingly useful where the natural soil is inclined to be of a light or sandy character; the latter will be considerably improved by an admixture of clay, which will be found to render it more suited to the culture of fruit trees and Strawberries in pots, Melons, &c. Advantage should also be taken of any opportunity which may occur to secure a quantity of lime-rubbish from any old buildings, which may be about being removed or under repair, as this material is of service to soils deficient in calcareous matter, and in the formation of Vine borders. Of well-rotted stable, or hot-bed manure, I need scarcely say a considerable portion should always be kept on hand; also a portion of dried cow, sheep, or deer dung; decayed Mushroom beds composed chiefly of horse manure; also a quantity of broken bones, charcoal, soot, &c., all of which should be kept separate, and in readiness in the soil-yard.

P. GRIEVE.

BELGIAN FARM-GARDENS.

THE possibility of making a decent living for a family out of a farm depends in a large degree upon soil and climate. A small farm of a few acres in England, and more especially in Scotland, means semi-starvation. We have seen several instances in which the thing has been tried, and lamentably failed. A case occurred not long since within our personal observation, in which a land proprietor, by way of experiment, let a piece of ground, extending to about eight acres, with a house upon it, for a merely nominal rent. The land was good, though a little rough, and the tenant set stoutly to work upon it. In two years, he gave it up as hopeless. Another person made the attempt, and he also, in the same length of time, begged to be released of his lease, which was taken off his hands. The experiment was then very properly given up, and the land absorbed into a larger holding. It is quite a different matter trying to farm on a small scale in the Bay of Naples or in Belgium. There the farming is in reality a kind of gardening. Soil and climate, as well as old engrafted habits, conspire to make it practicable for a man, wife, and children, to extort a living from a mere patch of ground. It is a pity that theorists who talk confidently about land distribution, do not, from any personal knowledge, tell us how it is to be satisfactorily accomplished. We say distinctly that the cultivation of lands in Great Britain will not prove advantageous unless on a considerable scale, with professional knowledge, and capital to hire labourers, to buy and keep horses, to purchase artificial manures, and lie out of returns in the ordinary course of business. As regards that garden of northern Europe, the more fertile part of Belgium, the appearance of things there is certainly very fascinating—the neat whitewashed dwelling and outhouses, the trim miniature fields, the orchards in blossom, the industrious and simple habits of the people, the spires of village churches peeping out among the trees, all give one notions of the

golden age, "when every rood of ground maintained its man." The very fertility, however, which produces this result is for the most part not natural. It is the effect of centuries of diligent application with the spade or plough, constant drugging with manure, and tact in changing the crops. But there is more than this. It is the result of intensely economical habits, of which we can hardly say there is any parallel in England. Without enumerating all the plants to which the Belgian farmer gives his care, the Colza, Poppy, Hop, Flax, Hemp, Chicory, Wheat, Rye, Buckwheat, and Haricot Beans may be named; and as root-crops or forage, Turnips, Beetroot, Cabbages, Peas, Vetches, Oats, and the common or scarlet Clover. This variety gives to the country a very pleasing aspect; there are no large fields lying bare, as with us, waiting for the Wheat, but they rather appear like a garden, where are large beds of flowers of every hue. In early spring, the scarlet Clover alternates with the bright yellow Colza, then the beautiful blue Flax; the little white stars of the Buckwheat contrast with the gaudy purple Poppy, and the large Tobacco-leaves, whose intense green recalls the vegetation of the tropics. Without these plants the owner never could pay either for the manure he puts in or his high rent, as Wheat grows very poorly. They require much labour, and the soil has no repose; the labourer is always digging with the spade, turning over the soil, hoeing, weeding, or harvesting.

English and Scotch farmers might take a lesson from the Belgian agriculturists in their prodigious care of manure—no wasteful exhalation, no neglect of the liquids which enrich the soil. We might almost say that the Belgian farmer is a reverential worshipper of manure. It is his idol, his treasury. In the first place, there is the manure produced in the cattle-sheds. No cow is allowed to go about in the open air; all stay within doors, and liquids which we too often see running to waste, are carefully conducted into covered tanks. Neither is the solid part allowed to be in the open air; it is covered from sun and rain, which destroy the ammoniacal salts, and trodden by three or four young cattle during the winter. In addition, the farmer collects from his ditches and streams aquatic plants, which he mixes with the manure, or uses them at once to hasten the growth of the Potato. He sends to a distance for the mud dredged from canals, and lime; in the nearest town he buys the refuse from tanneries and manufactories, animal black, cinders, street-sweepings, crushed bones, and the refuse of Flax and Colza. His younger children are out at dawn with a little cart, gathering up from the roads and fields all that, according to agricultural chemistry, can restore to the land what has been drawn from it. Peru sends its guano; and the farmer is seen in spring, sack in hand, sowing the precious powder on the barren portions of his land; and the flinty soil swallows it all with such promptitude, that it must be manured twice or three times a year. In no country is such high-farming carried on, and it would be ruinous without the rich return of these plants, and the accessory crops which are gathered after the principal ones. In Eastern Flanders, of 100 acres of land, 72 are sown with cereals and plants used in manufactures; 28 with roots and forage; but to this must be added 31 acres of after-crop, which gives 69 as affording excellent food for cattle, superior to common meadows, and which explains how poor land can pay a rent of £5 an acre. The second sowing consists of Turnips and Spergula after Colza, Flax, and early Potatoes; and the Carrot, which is sown in spring with the preceding crops, and carefully hoed after they have been taken away. The Clovers having occupied the ground during winter, leave it clear for the April sowing; and the giant Cabbage develops during the cold season, making a stem 6 feet high, and giving abundant and excellent leaves for milch cows. Culture thus pushed to the extreme, necessarily requires some capital, and it is reckoned that, through a system of rigorous parsimony and saving, double the sum per acre is used in Belgium to that employed in England, and two-thirds more in the best farms. In this way the most dense population in Europe can subsist on a soil so little favoured by Nature. Here it will be observed that the small farmers of Belgium, with their 10 to 50 acres, place their reliance on a variety of crops, such as we could not profitably introduce into England. We might say the same thing of small farming in Lombardy. There the land bears three crops at once—Mulberry trees, grown for the sake of their leaves as food for silkworms; Wheat beneath the trees; and Vines in the hollows of the ridges. In the south of France we see the same diversity; in some places Olive trees, for the oil they produce, taking the place of the Mulberry. In such parts, the country is like a garden; and with little winter, there is something growing all the year round. Turning to one of the most fertile parts of Belgium, all, as has been said, is charming—every road is bordered with trees; not a rise in the ground is seen; all is calm, uniform, and presents an image of quiet comfort and peace. Each house is detached, and surrounded with large Apple orchards, hedged in by Box, Holly, or Hawthorn, where the cows are brought to feed every

morning and evening; it is of one-story only, and thatched, containing four rooms, the first for meals, the second for the dairy and preparing the food for cattle, the others for sleeping-rooms. The old-fashioned oak furniture is a model of brightness; tin and copper utensils shine on the walls, which are whitewashed. The garden is gay with Wallflowers, Dahlias, and Hydrangeas, and the florists' flowers which are to be shown at Ghent. Outside, everything is in its place; nothing spoils the greensward; the ditch and manure-heap are banished; the latter is always under the roof of the stable or cow-shed. In this stands five or six large cows, the constant care of the farmer's wife, who gives them abundance of green-meat in summer, with straw, hay, and a kind of warm soup, mixed with Carrots, Turnips, or Rye in winter. Thanks to this nourishment, and the constant rest they enjoy, the animals give from fifteen to twenty-five quarts of milk daily. The tools are simple, but of first-rate construction; the plough is light, drawn by one horse, and works with ease, rapidity, and regularity. The harrows are of various kinds, triangular, rectangular, or a parallelogram; but the special tool with which the Fleming has fertilised sands, dried up marshes, and forced back the sea, is the spade. The proverb on the banks of the Scheldt is: "The spade is a gold mine to the peasant;" and different kinds are made for light or heavy soil. The fields are mostly square, and rarely contain more than an acre; the ground is curved symmetrically, the centre being the highest, so that the water drains down equally in all directions. Round the field, and a foot lower, extends a strip of Grass, three or four yards wide; still lower, a hedge of Elders is planted, which is cut every seven years; and, finally, the plot is surrounded by a ditch, bordered with trees of larger growth. Thus, each piece furnishes rich Grass, firewood every seven years, and timber for building every thirty years. The plough is generally used; but every seven years the sub-soil is turned to the top by the spade, and thus it acquires a depth unknown to all but the best gardens; the principal object being to produce Flax and butter, not cereals. The best farmers never sell their corn, but allow their cattle to consume it. Unhappily, the farm-labourer there, as elsewhere, does not enjoy much comfort; working harder than most men, he is the worst fed. Rye-bread, Potatoes, Beans, butter-milk, without meat or bacon, is the usual fare, chicory the constant drink; beer is reserved for Sundays and fair-days. His wages vary from 10d. to 1s., and he could never live upon it did not all the members of his family work without ceasing. When the day's work is ended, often by moonlight, the father cultivates his small field; his wife and daughters take up the poorly paid lace-work, instead of the old spinning-wheel, which steam has superseded; and his sons, when their field-work is done, bring up rabbits for the London market. Their little hands pick up every tuft of herbage on the road-side, and open up a large trade of exportation not to be despised. From Ostend alone there come to us 1,200,000 rabbits every year; these are skinned and cleaned in Belgium, where the skin is used for the making of hats. Yet, though their life is so hard, the towns do not attract the rural population. Habit and family traditions bind them to the plough; whilst every nine years, at the renewal of their lease, the raising of the rent fills them with anxiety, and poisons their existence. It makes them distrust all those who are making inquiry on the state of agriculture, and dissimulate as to the fertility of their land, and the produce they obtain from it. Western Flanders is crossed by a strip of land which is particularly difficult of cultivation; until lately it was scarcely inhabited, and covered with low brushwood and marshy Heath. The Reindeer Moss enveloped the trees with a layer of white ashes; abundance of Ferns and Moss grew, and the sickly appearance of other plants gave the country a sterile appearance. But by means of the Pine tree this land has also become valuable. About 30,000 young trees are planted on an acre; at the end of seven years these are thinned, and sold for firewood. The land must be rich and provided with Fir-poles, 3,000 to the acre; as it grows, the stems have to be tied, and liquid manure given to those plants which show yellow leaves; finally, at the time of harvest, numbers of work-people have to be gathered together for the picking. But whilst in England the whole of the ground is sacrificed to the Hop, there are in Belgium the most splendid crops of Wheat and Beetroot growing between. Chicory, like the Hop, is a very expensive article of culture; but it gives a rich return, estimated at £40 an acre. The produce of Colza is also very valuable. It will be seen that few sheep are fed in a country where there is so little pasture. Horses of great strength, and milch cows which give much butter, and can be fed in the stable, are considered most advantageous; and statistics show that more of these animals are fed on the acre than in any other country. It is to be remarked that the Flemish farmer has compensated for all the disadvantages of his soil and climate by a simple means within the reach of all—that of restoring to the land what it gives to the wants of men; the secret of agricultural chemistry.—*Chambers's Journal*.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

JUNE 10TH.

A GOOD exhibition and favourable weather brought together a large company on this occasion. Prominent among plants were Orchids, Pelargoniums, and what are termed stove and greenhouse plants; Cape Heaths were also shown in quantity and in excellent condition; Ferns and fine foliage plants occupied shady nooks, and there was an interesting display of new plants. Messrs. Lane's fine exhibition of Rhododendrons, too, formed an important feature of the attractions of the day.

Stove and Greenhouse Plants.—In class 1 Mr. J. Ward staged a fine group of plants, prominent amongst which were *Erica depressa*, *E. tricolor* Kingstoni, *E. Candolleana*, and *E. Cavendishii*. The same collection also contained well-finished plants of *Genetyllis tulipifera*, *Statice profusa*, *Anthurium Scherzerianum*, and a splendidly-grown plant of *Phœnocomma prolifera* Barnesii. Mr. J. Wheeler had a fine group, consisting of well-grown and profusely-flowered plants of *Pimelea mutabilis*, *Dipladenia amabilis*, remarkably fine *Bougainvillea glabra*, well flowered, but hardly at its best; *Dracophyllum gracile*, *Statice profusa*, *Rondeletia speciosa*, and a fine *Clerodendron Balfourii*. Mr. W. Kemp showed a well-grown group of what are termed half-specimens in this class, conspicuous amongst which were *Genetyllis tulipifera*, *Acrophyllum venosum*, *Boronia serrulata*, *Allamanda grandiflora*, and others. In the nurserymen's class Mr. B. S. Williams had twelve fine plants, including *Bougainvillea glabra*, well bloomed; *Ixora amboyensis*, with from twenty to thirty trusses of fine orange blossoms; *Erica Cavendishii*, in beautiful condition; *Azalea Chelsoni*, a glowing mass of scarlet; *Erica tricolor impressa*, well flowered; and a perfect specimen of *Aphelexis macrantha purpurea*, about 4 feet through. In class 3 Messrs. Jackson & Sons staged six fine well-bloomed plants, consisting of *Stephanotis floribunda*, a mass of pearly-white sweet-scented flowers and fresh green leathery foliage; a good *Anthurium Scherzerianum*; *Pimelea mutabilis*; *Azalea*, Sir Charles Napier; *Erica Cavendishii*, the best of all the yellow-flowered kinds; and a well-bloomed plant of *Dracophyllum gracile*. Mr. E. Morse, of Epsom, also furnished a nice group, including *Hæmanthus magnificans*, in charming condition; *Phœnocomma prolifera*; *Vinca alba*; and a fine specimen of *Erica coccinea* minor, rather past its best. In the open class for twenty stove and greenhouse plants Messrs. Jackson contributed a well-grown and effective group, in which were good plants of *Anthurium Scherzerianum*; *Aphelexis macrantha purpurea*; *Ixora coccinea*; *Tetratheca verticillata*, and others. Mr. G. Wheeler, also, had a well-grown group of smaller specimens. In class 5, Mr. J. Ward had a dozen fine half-specimens, including one of the finest spathed varieties of *Anthurium Scherzerianum* that we have yet seen, the spathes being nearly 5 inches in width, and brilliantly coloured. In the same collection were also the varieties of the fine old *Kalosanthes* (*Crassula*) *coccinea*, fresh and bright in appearance; and a plant of *Erica Massoni* major, nearly perfect. In the class of six plants, Mr. Kemp staged nicely grown specimens of *Rhynchospermum jasmoides*, profusely flowered; *Dracophyllum gracile*, and a fine *Polygala oppositifolia*. Foliage plants were well represented by some fine groups from Mr. W. Cole, Mr. G. Wheeler, Mr. B. S. Williams, Mr. Ritchie, and others. *Caladiums* of more than average merit came from Mr. Lambert, gardener to R. Segeleke, Esq., Herne Hill, these were fine fresh specimens about 4 feet through; and Mr. Robert Ritchie, gardener to H. Prance, Esq., of Hampstead, also had a nice group of rather smaller plants. Mr. G. Wheeler and Mr. G. King both showed nice specimens of *Caladiums*.

Orchids.—These were well represented, Mr. B. S. Williams having a fine collection, including well-grown plants of *Cattleya lobata*, a soft rosy-lilac flowered species, with a richly-veined lip; *Cattleya Mossiæ*, *Lælia purpurata*, *Anguloa Clowesii* with great yellow flowers, resembling deformed Tulips, and a fine specimen of *Saccolabium curvifolium*, bearing two erect spikes of orange-scarlet blossoms. Mr. W. Bull furnished twelve specimens, all in excellent condition. Among them were—*Cattleya Mendelii*, with pearly-white sepals and petals, and a rich blotch of amethyst-purple on its crisped lip; a fresh healthy plant of the new *Odontoglossum Roezli*, with four flowers much larger than when first exhibited; *O. Alexandræ*, bearing a nice flower spike; a fine plant of *Cypripedium barbatum grandiflorum*; and a plant of *C. superbiens*, with three fine flowers. In addition to these were plants of *Phalænopsis grandiflora*, with two flower-spikes, *Vanda suavis* with two spikes, one bearing thirteen fully expanded flowers, and a well-grown plant of *Dendrobium formosum giganteum*, with large ivory-white blossoms, and a great yellow-blotched lip. Mr. E. Morse, Epsom, also showed a nice group, in which were *Aërides Lobbi*, with two fine branched spikes of rosy-purple flowers; *Lælia purpurata*; *Stanhopea tigrina*, with immense crimson-blotched yellow flowers; and a nicely-grown plant of *Cypripedium superbiens*. In the nurserymen's class for six Orchids, Mr. Williams was again first with splendid plants, among which were *Cattleya Mossiæ*, profusely flowered; *Disa grandiflora*, with nine spikes bearing five fully-expanded flowers of scarlet and gold, the soft rosy lip being streaked with purple; *Lælia purpurata*, and others. Messrs. Jackson & Sons, of Kingston, also had half-a-dozen good plants, among which the most remarkable was a plant of *Sobralia macrantha*, bearing eight or ten richly-coloured flowers. Mr. W. Bull's collection contained the rare white-flowered *Palumbina candida*, *Cattleya Mossiæ*, *C. Warneri*, *Dendrobium citrinum*, and a good *Cypripedium barbatum purpureum*. In the amateur's class for twelve plants, Mr. J. Ward had a finely-flowered and well-grown group, in which were fine specimens of *Odontoglossum Alexandræ*, with seven good flower-spikes; *O. Phalænopsis*, well-bloomed; a fine specimen of *Phalæ-*

nopsis grandiflora, *Lælia purpurata*, *Cypripedium Stonei*, *C. villosum*, and a good mass of *Masdevallia Harryana*. Messrs. J. and G. Wheeler each had well-grown groups. Mr. J. Ward's half-dozen plants, staged in class 8, were in every way excellent, and included two fine specimens of *Odontoglossum Bluntii*, *Phalænopsis grandiflora*, *Dendrobium Dayanum*, and a fine plant of *Aërides Lobbi*, with two fine spikes.

Pelargoniums.—These were excellent. The best group in the fancy class came from Mr. Watson, of Isleworth, Mr. King, and Mr. Chas. Turner, of Slough. Among these, the most attractive variety were *Sylvia*, white, with bright rosy blotch; *Lucy*, white and deep rose; *Lady Carrington*, fine lilac; *Mirella*, deep rose, with a white eye; *Mrs. Alfred Wigan*, fine deep rose. Of large-flowered or show kinds, Mr. J. Ward had a splendid group, each specimen being about a yard in diameter. This group contained *Conflagration*, bright rosy-scarlet, with a black blotch; *Rob Roy*, rosy-purple, with a black blotch; *Caractacus*, a fine purplish-lilac, with dark maroon blotch; *Desdemona*, white, with a dark blotch; and *Rosy Gem*, a deep rose, with maroon spots. Mr. Chas. Turner staged a fine bank of new varieties, belonging to both the fancy and large-flowered classes, the flowers, in the majority of cases, being finely formed, and of the most vivid colours. The Rev. H. Matthews, of Foxton House, Leicestershire, staged three plants of a new variety, named *Mrs. Andrew Matthews*, a fine kind, with round smooth rosy flowers, with a black blotch on the upper petals.

Heaths.—These were finely grown, the principal exhibitor in the nurserymen's class being Messrs. Jackson, of Kingston, who had *Erica Vernoni* (a fine white variety); *E. oblata*; *E. Aitoniana Turnbullii*; *E. tricolor impressa*; and *E. Parmentieri rosea*. Mr. Morse, of Epsom, had fresh, well-flowered specimens of average merit. And in the amateur's class Mr. J. Ward staged six fine plants, including *E. elegans*; *E. ventricosa magnifica* (well-bloomed); *E. Eassoniana* (a fine white variety); *E. Cavendishii*; and *E. ventricosa grandiflora*, a glowing rosy mass of colour. Mr. J. Wheeler and Mr. W. Kemp, also had well grown collections.

Begonias.—Two or three collections of the old foliage Begonias were staged, the exhibitors being Mr. W. Walker, Acton, Mr. Lambert, Mr. T. Farren, and Mr. W. Foreman. Mr. W. Bull staged six new flowering varieties of the *B. Boliviensis* type, including *B. grandis*, a vivid scarlet; *B. Sparkler*, a rich orange-scarlet; *B. Anacreon*, a most profuse bloomer, of a deep rosy-scarlet; and *B. Glitter*, a vivid orange. These new kinds of Begonia promise to be plants of great value, inasmuch as they are of a comparatively hardy character and have bright glowing colours, qualities that augment their usefulness as decorative plants, for pot culture, and warm sheltered positions out-of-doors.

Roses.—Mr. G. Paul staged nine well-grown specimens, including *Monsieur Woolfield*, a fine light variety; *Madame Margottin*, a clear sulphur-tinted Tea; and *Jules Chretien*, well bloomed. Mr. W. Stoder staged two fine stands of cut Roses, the blooms of *Maréchal Neil*, being of fine quality; and Mr. Henry Easton, Star Cross, Devon, had a cut Rose, all the petals of which were curiously tri-lobed. Mr. Turner sent a new light Rose, named *Miss Hassard*, which promises to become a favourite.

New Plants.—Fine collections came from Mr. W. Bull, who had a magnificent group, many of which we referred to in last week's issue. Messrs. Veitch also sent *Sarracenia Stevensi*, *Tillandsia musaica*, *Dracæna hybrida*, a fine habited plant, with deep green foliage profusely margined and streaked with creamy-white and bright rose. The same group included a new *Cattleya*, of a creamy-white colour, with purple markings on the lip; *Adiantum Zahnii*, with fine leathery bright green pinnae; *Lilium Phillippense*, with linear leaves, and a large white flower, nearly like *L. longiflorum*; *Bignonia argyrea cærulescens*, a graceful climber, in the way of a *Cissus*, has deep green leaves, mottled and netted with silvery-grey.

Miscellaneous subjects.—Messrs. Jackson & Sons staged a fine basketful of a Saxifrage named *nepalensis*, but which appeared to be either *S. Cotyledon* or a kind closely related to it. Mr. R. Parker had a fine group of hardy herbaceous plants in pots, including a fine collection of *Pyrethrum*, in many varieties; *Pæonies*, *Iris*, and *Spirea japonica*. In this group were plants of *Erigeron subumbellatum*, *Lychnis viscaria rubra fl. pl.*, and *L. viscaria splendens*, with mauve-tinted flowers. *Gloxinias* were shown by Mr. Farren, Mr. E. King, and Mr. F. Lambert. Messrs. Haage & Schmidt showed a case of flowers from their new strain of double-flowered *Cinerarias*. Messrs. E. G. Henderson staged a collection of succulents, fancy *Pelargoniums*, bedding *Tricolors*, and a dozen and a half of new hybrid flowering *Begonias*. A basket of the graceful Fern-like *Thalictrum adiantoides* was much admired. Dr. Smee, Finsbury Circus, sent a dish of ripe Pears of this season's growth. Mr. B. S. Williams had a large and effective group of choice Palms, Ferns, *Nepenthes*, *Orchids*, and succulents.

Botanical Certificates were awarded to the following:—

Phyllanthum Lindenii (Bull).—A fine *Arad*, with large light green foliage conspicuously marked with ivory veins.

Maranta Leopardina (Bull).—A vigorous growing species, with apple-green foliage, marked on each side the mid-rib with dark shining green blotches.

Croton volutum (Bull).—A strong-growing species, with deep green contorted leaves blotched and veined with golden-yellow.

Macrozamia plumosa (Bull).—A graceful slender-growing Cycad, with arched foliage and narrow leaflets of a fresh green colour.

Dracæna Goldiana (Bull).—A robust and distinct species with dark green leaves, banded with grey, markings very distinct and beautiful.

Calamus ciliaris (Bull).—One of the most beautiful of all slender-growing Palms. Foliage bright green, closely pinnate. Well adapted for decorative purposes.

Dendrobium amoenum (Bull).—A pretty white-flowered species, the segments tipped with lilac-purple. Flowers delicately scented.

Tillandsia musaica (Bull).—A robust-growing species, with gracefully

arching deep green leaves, banded transversely with lighter green. Flowers deep orange-yellow. Very effective.

Erythrina Parcelli (Bull).—A strong-growing stove plant, with green ternate foliage, veined with bright gold. It deserves culture as a general decorative plant.

Areca nobilis (Bull).—A graceful pinnate Palm of a fresh green colour, with spinose petioles. It resembles a *Kentia* in contour, and is highly ornamental.

Cypripedium Parishii (Williams).—A strong-growing green-leaved species, bearing three or four large flowers on an erect spike. Sepals and petals marked with purple. Lip greenish.

Sarracenia Williamsii (Williams).—This is an interesting plant, already mentioned in our columns. It appears to be intermediate between *S. purpurea* and *S. flava*, and nearly resembles the last-named species.

Scolopendrium vulgare cristatum viviparum (Williams).—A fine fresh green-crested form of a well-known hardy Fern.

Vanda limbata (Williams).—A beautiful and rare Orchid. Alluded to last week.

Sarracenia Stevensii (Veitch).—A beautiful hybrid. Alluded to in our last week's issue.

Tillandsia musaica (Veitch).—A fine stove plant, alluded to above.

Dracæna hybrida.—A fine robust-growing plant with deep green foliage, conspicuously streaked and margined with creamy-white and deep rose.

Lilium Phillippense (Veitch).—A large white-flowered species from the Philippines, resembling considerably *L. longiflorum* in the flower, but readily distinguished from that kind by its extremely narrow leaves and slender stems.

Adiantum Zahnii (Veitch).—A robust form of the *A. Wilsonii* class, remarkable for its bright green leathery fronds, and distinct and effective habit of growth.

Nephrolepis davallioides furcans (Veitch).—A bright green form of *N. davallioides* with forked pinnae. A beautiful form of a well-known and valuable basket Fern.

Odontoglossum Rœzii (Bull).—A beautiful and rare white flowered Orchid, the petals of which are blotched with purple at the base; well worth culture as a companion to *O. vexillarium*.

Pleocnemia Leuzeana (Bull).—A beautiful Fern with ample spreading fronds of a lucid green tint, well worth general culture.

Floral Certificates were awarded to the following novelties:—

Ageratum Little Gem (Turner).—A dwarf blue-flowered form, resembling one shown by Mr. Chater some time ago; will be valuable for carpet bedding.

Pelargonium Countess of Dudley (Turner).—A nice addition to the fancy class, of a rich rosy-lilac colour, and free habit of growth.

Pelargonium Atlantic (Turner).—A free-flowering lilac-tinted fancy variety, the upper segments very deeply coloured.

Pelargonium Crown Prince (Foster).—A lively scarlet, with dark blotch on the upper segments.

Pelargonium Sybil (Foster).—A fine flat scarlet-flowered variety with darker blotch.

Pelargonium Gypsey (Foster).—A dark crimson-maroon-tinted flower of free habit.

Pelargonium Lord Nelson (Foster).—A deep maroon-purple, darkly blotched and veined.

Pelargonium Mrs. Andrew Matthews (Matthews).—A fine smooth soft-rosy scarlet flower of good form, and free habit of growth and flower. It has a good clear centre and deeply blotched upper segments.

Rose Rev. J. B. Camm (Turner).—A fine full flower of a bright rosy-lilac colour and a highly promising addition to its class.

WELL DRESSINGS.

FOR many years past the ceremony of decorating wells in commemoration of the introduction of good and pure water into Wirksworth, has been regularly observed at Whitsuntide, and this year was no exception to the rule, the railways bringing some 3,000 persons, all bent on a holiday and a ramble among the hills and dales, for which this part of Derbyshire is so famous. The prizes awarded were—first, £8 10s.; second, £8; third, £7 10s.; and fourth, £4. In the first prize, the well dressing took the form of a Roman alcove, with central recess and supporting panels. The ground of the recess was worked in Parsley leaves, which gave it a beautiful depth of colour, in the upper portion were the words "Unity is Strength." Just below this was a large shield with coat-of-arms of England worked in Laburnum flowers, Geranium leaves, and red Daisies; lions, &c., in coloured Wallflowers and yellow Pansies, whilst round the whole was a representation of the wreath we see depicted on the new half-crowns in circulation. The outside panels were done in grey and green Moss, with rows of white Daisies between, in imitation of stone-work, the inner panels having oblongs of white Daisies and border of red Daisies. The capital running along the top of the centre piece and panels was a very pretty piece of work, the end being in yellow and light-coloured pansies, with strings of Holly berries, while the centre was a scroll-work of dark purple flowers and red berries. Open ornamentation work was fixed at the top, whilst a dove in white Daisies surmounted the whole. The second prize well represented a drinking fountain in recessed archway, supported by two semi-pillars on each side and outside panels. This was a very pretty design, and most artistically carried out. The fountain was of oval-shape, worked in alternate stripes of Blue Bells, King Cups, and lines of red berries, the ground being grey Moss. The arch spanning the centre was also in grey Moss, with lines of Holly berries at intervals, and the motto, "England's Defence," over which was a large crown, surmounted by flags in scarlet Geraniums and Blue Bells—cannon on either side being worked in Sweep-heads, with wheels and mounts in Holly berries. The crown was very pretty, being worked in red Daisies, dark Pansies, Laburnum flowers, and small green Grapes, with mitre of red berries. A large scroll surmounted the whole in King Cups, and at the intervals along the top three pinnacles, dressed with borders of King Cups, and the centre with purple Stocks. In the centre, over the fountain, was a large star, with inner circle worked on white Lilac ground. In the ring were the words, "A living stream as crystal clear," done in red berries, on ground of Rhubarb seed, the centre portion of the star being worked in Bachelor's-buttons, Fir shoots, and Blue Bells. The side pillars were in scrolled form, worked with King Cups, Blue Bells, and Lilacs alternately.

THE GARDEN.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CAUSE AND CURE OF GUM IN FRUIT TREES.

THE formation of gum in fruit trees is a very common occurrence, and, as it is more or less prejudicial to the health of the subjects affected, it has long engaged the attention of horticulturists, whose opinions respecting it differ in a remarkable manner. Du Hamel admitted that gum, when introducing itself into the vessels of the tree, causes obstructions which are fatal to its vitality. Meyer, on the other hand, maintained that the flow of gum is not, in itself, a disease, but a symptom of disease, indicating merely an arrest of the supply and assimilation of the sap. From my own investigations into this subject, I have been enabled to decide between these contradictory opinions, and to establish the fact that the flow of gum in a fruit tree constitutes, of itself, a genuine disease. In the wood of a tree diseased with gum, a great number of vessels are always seen more or less completely filled with it; sometimes, they are entirely filled to a certain length, and, sometimes, the gum only forms a coating either upon all the periphery or only on one side. The gum first shows itself in very small drops, which gradually increase in size and touch each other, forming small irregular masses. Recent German observers have stated that the formation of the gum is due to the disorganisation and transformation of the internal part of the wall of the vessel, but the author has come to an opposite conclusion. In examining the wood of an Apricot tree from which large masses of gum were extracted, it was found that the vessels were marked with areolated punctures, and with a spiral line due to a thickening of the membrane; also that the surfaces of the masses of gum were marked with deep furrows corresponding with the spiral lines of the vessel-wall, and even with small projections according with the punctures. It is thus certain, in the author's opinion, that the gum has poured into the interior of the vessel, and that the marks upon it are imprinted from the vessel-wall. In the production of gum in the cellule by the transformation of starch, it has been observed that, on the first appearance of gum in the cellule, the unchanged starch gathers into small masses, around which forms a thin coating of gum. Gradually the starch diminishes, while the coating of gum increases, until at last the starch disappears altogether, leaving generally a vacant space in the centre of the mass of gum. Often the gum, produced in such considerable quantity, is formed neither in the vessel nor cellules, but in the spaces between the young tissues, generally between the wood and the bark, yet often also at the different depths in the wood. These gum spaces grow at the expense of the neighbouring tissues, which suffer important modifications: the cambium, instead of producing woody fibre, forms cellules in which abundance of starch is deposited, which starch subsequently becomes converted into the gum. This specific formation of a starchy parenchyma, which is never found in a healthy plant, may be considered as the first specially active phase of the disease. It is a true pathological indication, exhibiting the formation of a new morbid tissue by a specific transformation of the constituent elements of the normally healthy tissue. What then follows? In the first place, an exudation of gum into the interior of the vessels, and sometimes of the fibres; next, the appearance of the gum, at first, between the cells (probably, in consequence of a gummy degeneration of the inter-cellular matter), and afterwards in the interior of the cellular wall itself, the layers of which become separated by, and distended with, the infiltrated gum. In this case, also, it is possible that the substance of the cellular wall undergoes a partial gummy degeneration. However, this may be, the contact of the gum thus produced exercises a remarkable influence over the adjacent tissues. Although already undergoing a gummy degeneration, they, at the same time, manifest a great activity in forming fresh matter, and the

cellules on the margin of the affected space increase in size and number in an extraordinary degree. An organic action has been set up, quite analogous to that which M. Trecul has so well described in his account of the formation of swollen growths on the lips of bark-wounds, which are screened to prevent them from drying up. The vitality of the cellules, then, evidently, still exists in a very high degree. If, subsequently, the cellules in the immediate neighbourhood of the centres of gummy production give up the starch which they contain, if they become disorganised and exfoliated, and partially changed into gum, we must, nevertheless, recognise in this production of gum quite a different matter from such a purely passive and indifferent a phenomenon as a particular phase of the disorganisation of a dead tissue. It is a genuine disease which presents these special characters, and one in which we see the vital forces of the plant diverted from their normal course, and displaying an increase of energy prior to their final extinction. The study of the changes which occur in the gum-affected tissues enables us also to distinguish the prevailing character of the malady, and to see how, under its influence, the normal functions of the plant are deranged. The nutritive matters, laid up in reserve in the tissues, instead of contributing to the aliment and growth of the plant, go to the production of gum, and a portion of them, before they are transformed into it, collects in quantities around the gummy centres of irritation. We might, I think, almost draw a comparison between the effects of these centres of irritation on the organism of a plant, and what takes place when an insect punctures the bark and deposits its eggs among the tissues. In the latter case under the influence of a specific source of irritation, a gall is formed, the tissues become modified in their structure, and assume a different appearance, while the new cellules which are formed enclose in their interior a collection of alimentary substances (and of starch, in particular), which are intended no longer to supply the requirements of the plant, but to serve as food for the little parasite, that is about to be hatched and bred among the materials, which the vital functions of the plant, so deeply perverted by this singular disease, have been compelled to yield and store up within its reach. It is much the same with the phenomena connected with the formation of the woody parenchyma in those parts of the plant which may contain the elements destined to be employed in the formation of gum. These phenomena appear to result from the poisonous activity of the centres of gummy irritation, in the same way as the production of the gall results from the depositing of the insect's egg. The primary cause, however, of the poisonous irritation set up in those parts of the plant which are destined to become gum-centres, is not so obvious as the empoisoned wound and the laying of the insect's egg which produces the gall. But, if the primary cause of the gum-disease is still very obscure, its effects are, nevertheless, now well known, and, when we consider that the woody parenchyma communicates with the medullary rays, which extend through every part of the plant, and constitute the general store-house in which are laid up in reserve the nutritive substances for its support and growth, it is easy to understand how the formation of gum, which is effected at the expense of these food-stores, has no other limit than the final total exhaustion of the plant.

Remedies.

Among the remedial measures which have been proposed for the cure of this gum-disease, there is one, which, to my own knowledge, has been very effectual. This is the scarification of the bark. I have seen trees which were severely attacked by the disease, and unable to produce any but small and feeble shoots, completely restored to health, and sending forth fresh vigorous shoots, after longitudinal incisions had been made in the bark of the branches. The open wounds keep up a very active irritation in the bark, and the food-stores are diverted to the formation of new and healthy cellules, and cease to be drained away to the gum-centres, while the vital energies of the plant soon tend to resume their regular course. Scarification, in fine, acts as a powerful diverting agent against the disease. [The foregoing translation of a paper read by M. Ed. Prillieux before the Académie des Sciences, at Paris, will, doubtless, prove useful to cultivators whose fruit-trees are affected with gum.]

W. M.

NOTES OF THE WEEK.

— MAY frosts we are too familiar with in this country; June ones are happily more uncommon. A climate, with dangerous frosts occurring within a week or two of the longest day, can scarcely be called agreeable, and this we have experienced this year. On Friday week, 12th June), the frost in the neighbourhood of London was most severe. The young foliage of many herbaceous plants was destroyed; Potatoes were blackened in many fields and gardens; and the flowers of such hardy plants as Irises, Lilies, and Pæonies were killed. That favourite border flower, *Dielytra spectabilis*, has been cut down by frost three different times this year. Roses are generally a greater failure through frosts than we ever remember to have seen them. And so of most other garden products. After these experiences, it would be rash to say that we are at any time safe from frost in England. "On two nights," says Mr. Titus Salt, writing to us from Milner Field, near Bradford, "within the last week, the thermometer has registered 34° and 36°, with a bitter north-east wind; it is literally destroying all vegetation."

— IN France, where Strawberry culture is very extensively pursued, and the transport of the fruit to the great markets is an important consideration, small jars of baked earth have superseded baskets for the package of fruit of late. They hold about a quart of fruit each, and are conveyed in large baskets. The fruit is said to come to market in these jars in fine condition.

— SEVERAL forms of the Tree-Lupine form large, handsome, and well-furnished bushes in Mr. Ware's nursery at Tottenham, and are strikingly effective. There are various forms of these Lupines in cultivation; but those in the Tottenham nurseries are the best we have seen. It is surprising such handsome shrubs have not become common. They are covered with flowers, and are far more valuable plants than any herbaceous or annual Lupine in our gardens.

— LAST year Messrs. Veitch offered some handsome prizes for fruit; and with such satisfactory results that that firm has been induced to repeat the offer this year, the competition being fixed to take place on the 15th of next month, in the Royal Horticultural Society's Gardens, at South Kensington. The prizes, which, as will be seen by an advertisement in another column, are liberal, deserve attention, and will doubtless be the means of bringing together a highly interesting fruit show.

— THE Legislature, says the *Californian Horticulturist*, has granted permission for the issue of thirty-year city bonds, to the extent of 250,000 dollars, in aid of the next two years' work on the Golden Gate Park. This, though but half the amount which was desired, will serve to make the park a credit to the city, and one, indeed, which, at no very distant day, will be one of the finest in America.

— WE are glad to learn, from the *Revue Horticole*, that our friend M. E. André, editor of the *Illustration Horticole*, and designer of Sefton Park, Liverpool, has recently been decorated, by the King of Holland, with the order of the Couronne de Chêne, in recognition of the valuable services which he has rendered during the last four years in superintending some important improvements in the town of Luxembourg.

— A NEW classification of plants, with special reference to their distribution, is suggested by M. De Candolle, in the last number of the *Swiss Archives des Sciences*. Basing his system on the relations of plants to the physical conditions of heat and moisture, he recognises four great groups. One of these is essentially equatorial, whilst the others are repeated in the two hemispheres. De Candolle's names are Mégathermes for those plants which require a high temperature and much moisture for their development, Xérophiles for those which affect dry situations, Mésothermes for plants living at moderate temperatures, and Microthermes for those needing but little heat. There is still a fifth class, of only small importance, and now confined to arctic and antarctic regions, which the author designates as Hélisthermes, in allusion to the very small proportion of heat needed for their development.

— ACCORDING to a return made in conformity with instructions issued by the French Minister for Agriculture, the department of Aube has lost two-thirds of its Vine crop through the May frosts; Upper Charente, one-fifth; Lower Charente, one-third; Cher, one-half; Côte d'Or, from one-third to one-half; Gironde, one-tenth; Indre-et-Loire, one-quarter; Isère, one-fifth; Jura, one-third; Loiret, one-third; Loire-et-Cher, one-third; Maine-et-Loire, one-third; Marne, one-quarter; Meurthe-et-Moselle, one-half; Puy-de-Dôme, one-quarter; Rhone, one-quarter; Saône-et-Loire, one-third; Upper Saône, one-third; Savoy and Upper Savoy, have each lost one-quarter; and, finally, the Yonne has lost two-thirds. Adding up the specified figures, we find a sum of 6,535,603 hectolitres of wine, to which may fairly be added 1,464,397 more for the losses of the other departments of secondary importance, thus giving a round sum of

8,000,000 hectolitres; and, taking the average value at the moderate price of 25 francs per hectolitre, it would appear that the frosts last month have created a direct loss of 200,000,000f., or £8,000,000 sterling, to the proprietors of French vineyards alone.

— GERANIUM "arenarium," in our last week's "Notes," was a misprint for *G. armenum* of Boissier. It is a native of Armenia, and is perfectly hardy.

— AQUILEGIA WITTMANNIANA, of which there is now a large bed in bloom in Mr. Ware's nursery at Tottenham, is one of the finest of the Columbines, quite worthy of ranking beside even the finest Rocky Mountain Columbines, such as *A. cærulea*.

— THAT pretty aquatic plant, the Water Violet (*Hottonia palustris*), so rarely seen in good condition in gardens, is now blooming very prettily in Messrs. Rollisson's nurseries at Tooting. It grows in a large pond in deep water. The flowers are in whorls, like those of the Japan Primrose, and very beautiful.

— MR. JOHN FRASER informs us that the new park at West Ham, better known in its neighbourhood as Upton Park, is to afford a site for a very important flower show, to be held there on the 30th of June and 1st of July. Of the park itself a full description will be found at p. 434 of the last volume of THE GARDEN.

— As one of the curious effects of the great frosts of May, Mr. Ware, of Tottenham, informs us that, while large numbers of Roses worked near the surface of the earth perished, standards of the same age and same varieties escaped. This was doubtless owing to the greater cold and moisture near the surface of the ground.

— AT the recent exhibition, at Florence, M.M. Vilmorin-Andrieux & Co., 4, Quai de Mégisserie, were awarded a gold medal for their "Album," a splendidly illustrated work, containing carefully-coloured plates of flowers and vegetables, which are figured in their natural sizes.

— SIX HUNDRED lots of the Meadowbank Orchids which were sold at Stevens' on Wednesday and Thursday last, realised £2,000. The highest price given for any one lot was 42 guineas, and that was for Dawson's variety of *Lælia anceps*; *Cattleya exoniensis* fetched £31 10s.; and *Cypripedium insigne Veitchianum* £23 2s.; others fetched from £10 to £15 per lot.

— A NOVEL application of photography is described by an Italian correspondent of the *Philadelphia Photographer*. He had some fruit-trees that needed pruning, and there was no one in the neighbourhood who could attend to the work in season. He, therefore, photographed the trees, and sent the pictures to an experienced pruner in Turin, who returned them after marking where the branches were to be cut. The artist then pruned the trees himself, according to the directions.

— TRITOMA CAULESCENS we find is now in flower in the herbaceous grounds at Kew. It has a stout stem and glaucous broad fleshy leaves, which much resemble those of a caulescent Agave. This species is a native of the Stombergen Mountains. The plant now in flower has remained in its present position during the past winter. There is also, at Kew, a fine plant of *Lilium Szovitzianum*, producing richly-scented yellow flowers in abundance; and a tuft of *Allium odorum*, a mass of fragrant bloom.

— WE observe that a national lawn-mower contest is to take place at the Lower Grounds, Aston Park, Birmingham, in connection with the midland counties great show, which is to be held there on the 7th, 8th, 9th, and 10th of next month. At this contest the following prizes are offered:—Premier prize, gold medal, for the machine gaining most points; for the second prize, a silver medal; for the third prize, a bronze medal. A special prize, consisting of a silver medal, will be awarded to the best machine or other appliance for cutting Grass edges.

— THE current number of the *Revue Horticole* contains a coloured plate and a description of a handsome hot-house plant, *Vernonia centriflora*. It is a native of Brazil, and forms compact tufts from 12 to 16 inches high, flowering in November and December, when it exhibits numerous semi-globose heads of delicate lilac flowers, in scorpioid spikes on the terminal ramifications of the erect stems. The plant does well in a temperate house, in a mixture of free loam and spent hot-bed material for full-grown specimens, and a lighter compost mixed with heath-soil for younger plants.

— WE are authorised to announce that, with a view to accommodate intending exhibitors at the forthcoming great midland counties show, the last day for making entries has been fixed for Saturday next, the 27th inst., instead of the date announced in the schedule. Competitors for either of the silver challenge cups offered must deposit a sum of £2 at the time of making the entry. These deposits will be returned on the morning of the exhibition to such exhibitors as duly stage their exhibits. Arrangements have been made for holding a public dinner at 6 p.m. on the second day of the show, in order to afford exhibitors and others an opportunity for social intercourse.

THE FLOWER GARDEN.

ADONISES.

THESE belong to the *Ranunculus*, or Buttercup, family. They are chiefly natives of corn-fields in Southern Europe and Western Asia, and are dwarf in stature, with finely-divided leaves, and red, straw-coloured, or yellow flowers. There are about fifteen or sixteen species, most of which are annuals, and not very striking or ornamental in appearance; consequently, with the exception of two or three fine kinds, they are seldom seen in gardens. By far the most showy and finest of the species is

A. VERNALIS, of which we give an illustration. This is a compact-growing perennial plant, forming dense tufts, 8 to 15 inches high, of finely-divided thread-like leaves, which are disposed in whorls along the stems. It flowers in spring, when the tufts become covered with numerous large brilliant yellow, Anemone-like flowers, 2 or 3 inches in

species, are very finely divided into numerous narrow linear segments, and have a very graceful appearance. Individually, the plants are not very effective, as they are rather straggling in growth, possessing none of the compactness of habit which distinguishes *A. vernalis*; but, when grown in masses in borders or flower-beds, along with other autumn-flowering annuals, they afford a very pleasing contrast; and this is, indeed, the only way in which they can be employed to advantage. They do well in ordinary garden soil, and should be sown at the same time, and receive the same treatment, as the commonest annuals. A variety with larger flowers was formerly grown in gardens under the name of *Flos Adonis*.

Some of the other species (which are mostly annual corn-field or vineyard weeds in the south of Europe) are:—*A. flava*, a small French species, with yellow flowers. *A. micrantha*, a doubtful species, with small yellow or flame-coloured flowers—also from France; *A. microcarpa*, a Spanish species, with citron-yellow or somewhat flame-coloured flowers; *A. flammea*, an Austrian species, with large flame-coloured long-stalked

The Spring-flowering Adonis (*A. vernalis*).

diameter, a single flower being produced at the end of each stem. Native of Southern Europe and Siberia. This plant forms an excellent subject for borders, rock-work, or the margins of shrubberies, and will grow in almost any soil. It will come to greatest perfection, however, in a rich calcareous or sandy loam. Its compact habit and free-flowering qualities point it out as an eligible subject for pot-culture, and it is sufficiently showy to take a prominent place among some of our most popular window-plants. Of *A. vernalis* there are several varieties, the chief of which is *A. v. sibirica*, which differs from the type only in having larger flowers.

A. PYRENAICA.—This is another fine perennial species, from the Eastern Pyrenees, at present rare in cultivation, with large showy deep yellow flowers, resembling those of *A. vernalis*, but with broader obovate petals. It flowers in April and May, and may be grown in the same way as the last-named species.

A. AUTUMNALIS.—This British species, popularly known as the "Pheasant's Eye," is an annual plant which grows from 8 inches to a foot, or more, high, and blooms in the end of summer or early in autumn. The flowers are not more than an inch across, but are of a bright scarlet colour, with a dark spot at the base. The leaves, like those of the other

flowers; (this might, perhaps, be advantageously introduced into general cultivation). Others are *A. æstivalis*, a corn-field weed in the south of France, with small vermilion-coloured flowers; and *A. citrina*, which is, perhaps, a variety of *A. æstivalis*, with small citron-yellow flowers. W. M.

EFFECT OF THE SEASON ON FLOWERS.

SPRING flowers, this year, have had a short season and a brilliant one; sun, frost, and drought having made short work with them. Primroses, Violets, Forget-me-nots, Daisies, Aubrietias, Dielytras, Auriculas, and many more, could hardly be said to have been here until they were past; and yet they have seldom been more glorious. Snowdrops, Crocuses, Daffodils, Tulips, Hyacinths, Anemones, all came in in excellent condition, and went past, as it were, with a rush. Some were cut down suddenly by frost, as the *Dielytra spectabilis*; others, were dried up between frost and sun, like the exquisite *Myosotis dissitiflora*, and many of the *Viola cornuta* section; others, again, such as *Polyanthus* and *Auriculas*, were half scorched as soon as opened. Cowslips have hardly been able to flower at all in dry meadows; the new *Primula japonica* has had hard work to hold its ground with the frost and the sun acting by turns, on its juicy tuft of fine foliage. Its crimson spikes are now,

however, about the finest things in the spring garden. It stood the frost of winter well, but it does not like the alternate freezing and scorching of this spring, and many of its leaves are partially browned. The great want of this and other spring plants this year has been water, and that has been scarce; and, where spring flowers are grown by many thousands, it is found impossible to water them on account of the labour which the operation involves. The winter has had a curious effect upon some so-called hardy plants. For instance, the whole of a nice collection of Pentstemons, in the open border, has succumbed to the cold. Hollyhocks have likewise suffered severely. The majority, however, of herbaceous plants look well, and seem to have enjoyed the dry winter. The drought has been most persistent. Seldom have ponds, ditches, or springs been so low. Rain is still wanted to develop the clustering buds of Roses, and to start into growth and beauty the hosts of bedding and sub-tropical plants that have recently been put out.

D. T. FISH.

EVERLASTING FLOWERS.

THE various genera that may be grouped under this heading are all of considerable decorative value in the flower garden and conservatory during the summer, and also in the house during the winter when carefully dried and preserved. It will be most convenient to take the group in alphabetical arrangement, and descant on the properties of each as the list is passed in review. The beautiful *Acroclinium* roseum and its white variety—both introductions from South-West Australia—are very extensively grown, and are much esteemed for cultivation in pots, and for forming beds or patches in borders in the open ground. Though classed as half-hardy annuals, they may be advantageously sown on warm sunny spots in April; but the soil must be open and rich. It is a good plan to sow some seed in pans in March, in a gentle heat, and when the plants are large enough to prick them off into 48-pots, about three plants in each, for blooming early in a greenhouse. The *Acroclinium* grows about 12 inches high, and throws up numerous flower-stems. In the open ground the seed should be sown thinly in drills, and room allowed to the individual plants to grow and branch freely. They then become bushy, grow freely, and supply an abundance of flowers to cut from. Next comes *Ammobium alatum* (the Winged-stalk Sunflower). This can also be grown as a perennial if protected from frosts; but, on the whole, it is best to treat it as a half-hardy annual. It is by no means so commonly grown as the *Acroclinium*. *Ammobium alatum* forms a kind of tuft of leaves at the base of the flower-stalks, which are tall, erect, and branched, with flowers having a centre composed of tubular yellow florets, with a fringe of white scale-like petals surrounding the disc. Seed of it should be sown early in March in a pan placed in a cold frame, and the plants should be put out in a warm border in May. *Gnaphaliums* are included under the head of Everlastings; but, as they can be purchased so cheaply in London, being largely imported from France, it is not worth while troubling about their cultivation. On the other hand, the *Helichrysums* are among the most valuable of the Everlastings, furnishing a great many shades and tints of colour, from white to the darkest maroon. All the large-flowered double varieties, no doubt, came originally mainly from *H. bracteatum*, an introduction from New Holland, though some trace their descent back to the large-flowered *H. macranthum*. By means of careful selection very fine double flowers can now be obtained, while the plant is of very easy cultivation. What is known as *H. compositum maximum* affords the finest strain. The *Helichrysums* should be raised in a gentle heat; and, if it is possible, to form a small bed in a warm house, or under a frame on a bed of decayed leaves and a little manure, and the seed sown broadcast, the plants will become well rooted by the time when they ought to be planted in the open ground. The Continental seed-growers have succeeded in originating a dwarf free-branching strain, which, growing from 12 to 20 inches in height, is much better adapted for small gardens than the type which grows from 2 to 3 feet. The soil for *Helichrysums* should be light and rich, and the plants should be placed in the open ground as early as possible. *Helipterum Sandfordi* is a very handsome Everlasting, bearing large clusters of golden-yellow flowers, but, as it is of a tender

character and requires careful culture, it is not much grown. The *Rhodanthe* is one of the most popular of Everlastings, and, like the *Acroclinium* and the *Helichrysum*, is very extensively cultivated. The slender, elegant habit of growth of the plants, and their charming Daisy-like flowers, make them general favourites. *Rhodanthe Manglesii*, or Captain Mangles's *Rhodanthe*, first came to us from the Swan River and New Holland many years ago. This grows from 12 to 18 inches in height, with free-branching stems and solitary flower-heads, which are of a charming rosy hue, the disc of tubular florets being yellow. In 1861, or thereabouts, Mr. William Thompson, of Ipswich—to whose enterprise we are indebted for some of the best of our more recently introduced annuals—was enabled to introduce two supposed new species from Western Australia; one, *R. maculata*, which, in general habit, approaches very nearly to *R. Manglesii*, and has rosy-pink flowers, stained at the base near the disc with a deep sanguineous blotch, to which the name *maculata*, given to it by its discoverer, Drummond, the celebrated Swan River botanist, bears reference. There is a white variety of this, known as *Maculata alba*, the outer fringe of petals, or scales, as they are termed, being white. *R. atrosanguinea* has certain distinct characteristics which seem to stamp it as a species; for instance, the buds are erect, instead of half-pendulous, and the flower-heads have a deep bronzy-red disc and a self-coloured striped ray of a deep rose colour, the outer scales being of a silvery hue, as in the other types. The *Rhodanthes* make very charming pot annuals. The best mode of cultivation is to sow the seed thinly in pans in a gentle heat, in February or March, and when the plants are large enough to handle to prick them off into 48-inch pots, about six plants in a pot, and let them flower without further molestation. The plants should be transplanted as soon as they can be handled, as they do not succeed well if moved when older. It is better to transplant to the flowering-pots than to sow the seeds in them, as they are apt to fail to grow. If transplanted to the open ground, a nice light rich peaty soil should be prepared for them. Nearly forty years ago, Drummond sent to England from the Swan River two species of the genus *Morna*, *nitida* and *nivea*, since known as *Waitzias*. The *Waitzias* have something of the aspect of a *Helichrysum*, but are mostly of a dwarfer and more restricted habit of growth, with foliage less obtrusive in character. The best known and most generally cultivated species is *Waitzia grandiflora*. This is the most robust grower of all, and has the largest flowers. It grows from 1½ to 2 feet in height, and bears clusters of large yellow flowers with an orange-coloured disc. It should be treated as a half-hardy annual; the seed should be sown in pans about the middle of March, transplanted to pots, and grown close to the glass in a moderate temperature only, to prevent weak growth, the final transplanting to the open ground being at the end of May. Lastly comes the genus *Xeranthemum*, represented by varieties of *X. annuum*, introduced from the south of Europe. The plants have an upright branching growth, and the flowers range in colour from white to deep violet. The original type grows from 2 to 2½ feet; but there is a dwarf form which only reaches 1 foot in height. The seeds should be sown thinly in the open border. In order to have Everlasting flowers as well preserved as possible, the flower-stalks should be cut just as the blooms are beginning to expand, or when they are not more than half open, tied up in small bunches, and hung up in a cool place to dry very gradually. The flowers of the *Xeranthemum* are apt to fade, and, in order to prevent this as much as possible, they should be dried quickly in the dark, in a very warm dry atmosphere.

R. D.

PRIMULA JAPONICA OUT OF DOORS.

THIS plant is doubtless hardy in the open air; that is, it stands the winter well in a dormant state, almost wholly denuded of leaves—as much, and more so, than our common English Primrose. This utter loss of leaf has caused alarm in some quarters. The plants have been taken for dead, because their crowns were bare of foliage—this Primrose, in fact, being wholly deciduous; while dormant, it seems quite as hardy as our own Primrose. I made a bank for this new Primrose in the end of March, and transferred a fine lot of plants to it early in April. The bank was due south, with a gentle slope. The

plants soon responded to the genial condition of their improved site, and shot forth with marvellous power; the crowns burst into leaf with the force and size of spring Cabbages rather than common Primroses. The foliage of this plant is ample and beautiful, forming a sort of natural vase. Presently, the sun and the frost played alternately sad havoc; and the drought and east wind did their worst to ruin them. They marred their beauty considerably; but, fortunately, could not destroy the flower-stems, which have shot up with a strength and beauty unknown to all other Primroses. They are now throwing up stem above stem and umbel above umbel four and more deep, and have a grand effect. Of course they would have been much finer but for the frost, the sun, and the intense drought; perhaps, too, they would have been taller in an eastern, western, or northern aspect. As this Primrose will continue flowering through June, it is probable that a southern site will prove too hot for it. In all our trials this new *Primula* is glorious; the colour is most intense, and each plant has come perfectly true from seed. The true *P. japonica* is far superior to any of the other varieties that I have bought; the colour is most brilliant, and the style and character of the plant all that can be desired. I hope, in a few years, to fill the pleasure-grounds with thousands of it; it will prolong the season of Primroses for two months; I have not succeeded with any of the imported seed. We gather the seed of our own plants, and sow it the moment it is ripe, in pans in a cold pit; as soon as the plants can be handled we prick them off, and, when big enough, plant them in rich light soil 6 inches apart out of doors. From thence they are transplanted to where they are to bloom with good balls in March and April; old plants promise to bloom with equal strength and far greater profusion than young ones. Without doubt, this is one of the greatest acquisitions to our hardy flowers of late years, and I hope the time is at hand when everyone will be able to hail this queen of the Primroses, not only in garden and border, but also in mead and forest.

D. T. FISH.

IRIS SUSIANA AND OTHER SELECT BORDER PLANTS IN SCOTLAND.

HAVING noticed in THE GARDEN of the 6th June some remarks on the culture of *Iris susiana* at Stonehouse, I thought that some account of my experience with the same plant in Scotland might not be uninteresting. I have grown this *Iris* here (Ormiston House, Kelso), for these last six or seven years; during the most of that time it has been placed in the mixed herbaceous border, without, however, any success as regards flowering it. I must tell you, however, that the soil of my garden is strong clay, and that it has required a large addition of sand to make it at all amenable to the growth of the finer roots of herbaceous plants. About two years ago I prepared a bed especially for *I. susiana*; it was made up of a mixture of peat, leaf-mould, and sand, about 1½ feet deep; in this I planted all I had of it, and have not since disturbed it. The plants have grown much more luxuriantly than they had done before, and I am glad to tell you that the first flower appeared about three or four days ago, and there is also a prospect of more yet to come. The flower is very large for the size of the plant, the petals measuring rather more than 3½ inches across; several people interested in these matters have seen it, and have been quite delighted with the strange appearance of the flower. The plant is quite hardy here, and I think now will flower every year. What it dislikes above all things is being transplanted or disturbed in any way. I may mention that the bed I prepared for it is at the foot of a south wall, warm, and well protected. I have also had an unusually large display of flowers on many other herbaceous and Alpine plants this spring. Among others I may mention—*Primula luteola*, several plants, with seven large spikes each; *P. Munroi*, with a great profusion of bloom; *Silene quadridentata*, a beautiful delicate little plant in fine flower; *Dianthus alpinus* and *neglectus*, both lovely; and *D. fragrans*, so covered with flowers that the leaves have been quite hidden. *Androsace lactea*, *pyrenaica*, and *villosa*, good tufts full of flower; *Mitella aphylla*, a pretty little plant with white flowers; *Aquilegia glandulosa* and *cærulea*, in great beauty; *Cypripedium Calceolus* and *spectabile*, *Hypericum verticillatum*, *Erodium macradenium*, *Delphinium nudicaule*, *Arenaria purpurascens*, *Globularia cordifolia*, *Geranium argenteum*, *cinereum*, and *lancastricense*. *Libertia formosa* has twelve fine flower-spikes on it; this is a plant which does not always flower well here. We are, I think, indebted to the unusually mild winter for the quantity of bloom which we have this season. *Veronica taurica* one of the best of its section, *Linum tauricum* hardy and free, taking the place of *L. flavum*, which does not do well here, are all in fine condition; as is also *Eriogonum subumbellatum*, which is flowering this season for the first time. I have grown the plant for several years. We have likewise in bloom *Campanula turbinata* and *Alyssum olympicum*; and *Spiræa*

palmata, too, is showing several fine heads of flower, which will be out in a few days. *Iris pallida* is very fine just now; also *Chrysobactron Hookeri* and *Lotus corniculatus* fl. pl., both very showy. *Myosotis alpestris*, a difficult plant to keep over winter, is fine this year. *Phlox Nelsoni* has been beautiful, and *Iberis Tenoreana* one mass of flower; this is a plant that requires to be raised from seed every year, as the old plants never stand the winter without protection. The fine *Campanula pulla* is just coming into blossom; *Nertera depressa* was very beautiful in a pot last autumn, the whole surface of the plant being covered with its beautiful red fruit.

WILLIAM B. BOYD.

PEGGED-DOWN ROSES.

I AM convinced that the system of pegging down Roses, where it can be put into execution, is one of the most advantageous which the cultivator can adopt. I have seen large quarters of Roses treated in this way. The long shoots are laid down in the most convenient direction, and pegged into the soil, along their length, with strong wooden pegs or hooks. All soft and not thoroughly-ripened shoots are cut entirely away. It is immaterial in this method of culture whether the main shoots thrown up during the year are employed for pegging down, the old being entirely removed, or whether the latter are in part left on, being somewhat retrimmed, and the upright growth entirely removed close to the main laid-down stem. Either plan has its advantages, and must depend for adoption much upon the grower's skill. One special advantage of this mode of culture under the latter mode of procedure (that of cutting back the old rods) is, that in many varieties the young upright growth of the season will be found to have emitted roots where pegged into the soil, especially if this has been deeply done. Thus we get not only a plentiful supply of blooms during the flowering season, but also a stock of rooted plants, and that with a minimum of trouble. An experienced eye will readily detect, during an examination of these pegged-down branches, which shoots along their length indicate separate root action to have taken place. It is well to go critically over the beds in November and take off those which are fit for removal. If these are potted off (the safest way) and subjected to the customary routine of winter treatment under glass, they will form excellent plants, either for pot culture or for planting out in beds, in the following May or June. The second time at which the laid down rods will come under examination is when the operation of pruning is being performed. There will then be found many of the upright clusters of shoots exhibiting indications of having emitted roots, though not in sufficient quantity to justify their removal as separate plants with due prospect of after growth. In such cases it will be well to leave the rods undisturbed, pruning the doubtful individuals alluded to back close to the main branch, and subjecting that to any further trimming up the operator may think proper. Every one of these will certainly be well-rooted, and fit for separate existence the following autumn. The ground on which pegging-down takes place ought to be made somewhat fine, and the whole quarter will be the better for a rich mulching as soon as the laying down is completed. An application of liquid-manure from a garden engine before the blooming season commences, and after the first rush of flowers is past, will not be without benefit, as this method of culture requires the stamina to be well maintained. It must, of course, be understood that it is a work of time to get the "stools" into good condition. Rods of 10 or 12 feet long, and of proportionate substance, are not the produce of newly-established plants. Of course a beginning can only be made with dwarfs; plants upon stocks of any kind, except *Manetti*, are totally unsuited for the purpose. There are many who, on looking over their Rose trees, preparatory to pruning, will find that some of the more vigorous growers have thrown out long substantial shoots. Here, then, provided there is border space, is the exact material for the experiment. Remove the sappy points. Cut back all laterals close to the stems, bring those down in convenient directions, taking care not to break them at the collar, and peg them into the soil according to their length. Pegs may be formed of strong branches of any trees, the hook in the form boys cut for nutting, one limb being left sufficiently long to enter the ground 9 or 10 inches, so as to clip the branch firmly, into a hole 2 or 3 inches deep at the point of contact with the soil, which ought to be made fine, in order to aid the emission of roots. All growths, except the shoots pegged down should be cut away from the heart of the plant, and of those of the season only a few of the strongest should be permitted to remain. Anyone who has observed the manner in which *Aucubas* are layered from a centre stool will comprehend the system, only I do not recommend "tongueing" Roses which will put forth roots in time without a tongue. Hybrid perpetuals, or other free-growing continuous bloomers, not succeeding satisfactorily upon walls, may be taken

down and dealt with as indicated above, provided there is bed or border room. Many a red-spider haunted, scrubby wall Rose, if worth the trouble, might be converted from a blemish into a beauty by adopting the plan just alluded to. Let those who doubt take heart and try. Pegged-down Roses must not be subjected to lifting or root pruning. They must become established fixtures, and their nourishment must be kept up by artificial means. It is certain, however, that in a thorough Rose soil—naturally so, or made so artificially—they appear more vigorous in growth, deriving as it were, additional stamina from the moisture of the ground. Charles Lefebvre, Madame Victor Verdier, John Hopper, La Brillante, Madame W. Paul, Victor Verdier, Gloire de Dijon, Senateur Vaisse, and indeed a host of high-class perpetuals of the vigorous kinds are adapted for this mode of culture. Baroness Rothschild, Marquise de Castellane, Mademoiselle Eugénie Verdier, Comtesse d'Oxford, and Paul Neron, amongst newer kinds, are also well worthy a trial. When the young plants are separated at the spring pruning, unless potted and put under glass, many of the weaker rooted ones will be lost, before becoming established, if planted out in beds. Under any circumstances, where this is done, whether in autumn or the following March, it will be desirable to cover the beds with a heavy mulch of Cocoa-fibre refuse.—*Queen*.

Scentless Violets.—I am very fond of scentless Violets. They come in when the sweet ones are gone, and their prettiness almost makes up for their want of fragrance. For the last week or two, *Viola montana*, with its lovely pale blue and white flowers, has been one of the gems of the garden. *V. obliqua*, which I have, also, under the names of *V. tuberosa* and *Pensylvanica*, is very effective with its large long-stalked deep blue flowers. I have a very handsome variety of *V. palmata*, with great blue flowers, splashed with white. The flowers and foliage of the closely allied *V. delphinifolia* are very pretty. I was greatly delighted this spring to flower the beautiful yellow-flowered North American *V. pubescens*, which seems now to have established itself here. *V. biflora* also flowered well in a cold pit. *V. sororea*, closely allied to our British *V. palustris*, is pretty, and does well if grown in peat and kept moist. Some years ago I had, I think, from Mr. Tyerman, a North American species, *V. semperflorens*, which completely smothers itself with large pure white flowers, and is most effective. I have lately procured the white and rose-coloured varieties of *V. hirta*, and the white ditto of *V. Riviana*, with which I hope to be much pleased if spared till another spring. *V. Munbyana*, of which I have only the blue variety, is most effective as a rock-work mass; and the little blue and white *V. palmensis* looks very well when mixed with *V. lutea*. I have, as yet, failed to grow *V. arenaria*, *mirabilis*, *pedata*, and *pedunculata*, but hope to get them again and succeed.—H. HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rare Irises (see p. 499).—Mr. Elwes will find some of the species of Iris about which he inquires in Messrs. Ant. Roozen & Son's Catalogue of this year, viz.:—*Iris kumiaonesis* or *kamoonensis*, *I. aurea*, *I. sicula*, and *Xiphion Histrio*.—SALMONICEPS.

Direction taken by Twining Plants.—Can any of your readers tell me why the stems of some plants invariably twine with the sun, namely from right to left, and others follow a different direction? The stems of the Honeysuckle always twine from right to left, so do those of the Hop, and the Bryony; but the Convolvulus, and the Dodder take a contrary course.—BERRY GROVE, *Liss*.

Mesembryanthemum sessile album.—This is a pretty succulent plant, well worth the attention of all who use such plants for bedding purposes. In habit it is very dwarf and spreading, resembling a miniature Cactus, its pulpy leaves or stems being thrown out from each other in all directions. It grows about $\frac{1}{4}$ of an inch in length, and $\frac{1}{8}$ of an inch in diameter. Its colour is light green, and it is covered thickly with minute hairs, so that it has quite a bristly appearance. The flowers are small and white; this plant has already been used for bedding purposes, and gives the greatest satisfaction. It is moderately hardy, grows freely, and is easily propagated.—D.

Giant White Quilled Daisy.—This is the finest of all white Daisies, I had almost said of all Daisies, but the largest is the Crown-flowered, a huge mottled kind that is too late, too large, and not sufficiently floriferous to be of much service. The White Quilled Daisy on the other hand is amongst the very earliest; I saw it in bloom in the open air at Christmas, and it is still a mass of blossom. It is a strong grower and blooms most freely. The flowers being snow-white, and as densely quilled, and as full and round as those of the best German Aster. It never shows a hollow centre, and makes a capital flower for nosegays.—A. D., *Bedfont*.

How to Manage Rooted Cuttings and Seedlings.—Order your plants when you have got a nice sweet hot-bed (not too steamy)—one on the decline is preferable, with the heat at about 65°. When you receive a box of rooted cuttings, immerse them in water at the same temperature. When they are all wet, proceed to pot them into 60's, using nice sandy warm soil. See that the roots are separated and naturally spread out in the soil, without injuring them. Place the plants in the frame, keep them shut up close for a few days, be careful of damp, and admit air as soon as they get established. If the weather permits, let them be slightly aired each day, but do not allow them to flag from too much air or sun.—H. CANNELL.

THE ARBORETUM.

THE MADRONA.

(*ARBUTUS MENZIESII*).

THE Californian *Arbutus* or *Madrona* is a tree 25 to 50 feet in height, and about 12 inches in diameter, with smooth bark, red or green, according to the season of the year, and exfoliating in thin flakes, the new bark being green, and gradually changing to a bright red. Hence, from its colour, it is sometimes called in Eastern Oregon, "Mountain Mahogany." It is unbranched for some 7 to 8 feet from the base, and forms an umbrella-shaped summit, with a rather open growth like a Maple. The port of the tree is rather crooked, and with its glistening leaves and smooth mahogany-coloured bark, and bright bunches of white flowers, it presents a very striking appearance when seen in the occasional openings of the dark Fir forests of the north-west. It is not a social tree, being rarely seen in more than one or two together, and then only at considerable distances apart. It is certainly one of the most ornamental trees of that region, and already, even in California, is cultivated as such in private grounds and parks, and in the clumps of shrubbery so commonly used to shade dwelling houses in San Francisco, and other towns of that State. Dr. Newberry remarks that the large, thick, and lustrous leaves, and the smooth and coloured bark, give this tree a tropical look, recalling, by its general aspect, the *Magnolia grandiflora* of the Southern States of America. On the Pacific coast the *Madrona* has a wide distribution, being found over most of the State of California, and to about the northern end of Vancouver Island. In the valley of the Sacramento it is common, and all through the Willamette Valley I saw large trees of it. Here it is often called "the Laurel." East of the Cascade Mountains it is rare, but I am informed by Colonel Drew, and other travellers who have gone across "the great descent of Fremont," that on the isolated hills in that region it is found in stunted forms here and there. It is never found in the depths of the Pine forest, but only in the sunny openings when light and warmth now and then enter. It seems very indifferent as to the soil in which it is found, preferring, if any, dry stony soils, being often found on the bare side of a mountain, on the edge of a cliff on the sea shore (as about Victoria Harbour), or on the numerous islands in the Haro Archipelago and the Gulf of Georgia. It is not found at any great elevation, being essentially a tree of the lowlands, where it flourishes in great perfection. As an ornamental tree, I think it would soon be exceedingly popular, being perfectly hardy anywhere in Britain. In some of the places where I have seen it growing in perfection, 3 or 4 feet of snow must lie for months in the year, and the tree be often subjected to a temperature at and below zero. The wood has not been applied to any important economical purpose, though from its hardness and box-like character, I think it might be used for the rougher kind of cabinet work, and even for wood engraving of the less artistic description—such as play bills, posters, &c.—in fact any of the purposes for which mahogany is now used. In California, the wood is used to some extent for making the wooden stirrups so commonly used in the State. We have seen this tree even larger and finer than it is thus described by Mr. Brown in his "*Horæ Sylvanæ*," and should like to know how it succeeds in cultivation with any of our readers. We have seen it at elevations of 5,000 feet, and in company with trees and shrubs quite hardy in our gardens, and it seemed to attain a greater height than any *Arbutus* we have elsewhere seen.

THE TIMBER CULTURE ACT AMENDED.

By Act of Congress approved March 14, 1874, the former enactment to encourage timber growing upon the prairies has been amended. The new law is free from some of the objectionable features and uncertainties of the altogether impracticable old one, and makes the entry and use of land for the purpose mentioned somewhat more feasible and satisfactory. From a circular issued by the commissioner of the general land office, we gather the most important provisions of the law as it now stands. Persons who are heads of families, or over twenty-one years of age (without distinction of sex), and either citizens of the United States, or having declared their intention of becoming such, may enter not more than 160 acres of land, either minimum or double minimum (lands valued at 1 dollar 25 cents. or 2 dollars 50 cents. per acre), by filing an affidavit of such intent in the local land office. The person entering the land must break and plant with trees one-fourth of it; one-fourth of this required fourth must be broken within one year from the date of entry, another fourth within two years, and the remaining half within three years. One-fourth of the area required to be planted must be planted within two years from the date of entry, another fourth within three years, and the remainder within four years; the trees to be not less than

12 feet apart each way. It is therefore required that the land be broken one year and planted the next. After having been planted the trees must be protected, cultivated, and kept in healthy growing condition for eight years next succeeding the date of entry. In case of the death of the person entering the land, his heirs may continue the occupation and care of the trees and complete the title. The land required under this act is therefore not liable for debts contracted previous to the issue of the final certificate. The fee to be paid on entry is 10 dollars, and the commissions of the officers of the land department in the whole amount to 8 dollars more; the total 18 dollars being the full charge up to and including the final proof of occupation and fulfilment of the required conditions.

VIRGINIAN CREEPERS AND VINES.

THE three genera *Vitis*, *Cissus*, and *Ampelopsis*, are, in their organic characteristics, very closely related to each other; the particulars in which they differ may be thus described:—

VITIS (Vines).—These have hard woody stems, and woody, very tough, persistent branches, which are not articulated, or jointed, but divided into sections by knots. The leaves are simple, more or less lobed, very rarely lacinated, or deeply divided. The fruit is produced in pendent bunches of greater or less size, and consists of large, edible, vinous berries, the juice of which in most cases can, if need be, be fermented.

CISSUS.—These have corky-wooded stems, and articulated or jointed, often shrubby, branches, swollen at the joints, where they are frequently liable to break off. The leaves are more or less deeply lobed, the lobes being large, sometimes nearly entire, or more or less toothed. The berries are very small, produced in small groups on erect stalks which form a kind of capitate or head-shaped umbel, and furnished with tendrils. They are not edible, and are incapable of yielding wine.

AMPELOPSIS.—All the general characteristics of this genus approach very closely to those of the genus *Cissus*, the chief and almost only difference being found in the leaves, which are deeply cut, pinnate or bipinnate, the pinnules being of greater or less length, and sometimes toothed. Some species have large, fleshy, turnip-shaped roots, while in others they are perfectly tubercular and spherical. Our illustration exhibits the manner in which the leaves of one species (*Ampelopsis dissecta*) are divided.

AMPELOPSIS DISSECTA.—A vigorous-growing climbing shrub, producing a great number of running shoots. Stem, twining, with long slender branches, covered with reddish bark; leaves, pinnatifid, with long toothed segments; fruit, small, nearly spherical, bluish, glaucous. This species is remarkably ornamental, on account of its elegantly-cut leaves, and is very hardy. It was first raised in the gardens of the Muséum at Paris, from seed sent from China by the Abbé David.—*Revue Horticole*.

Leaves of *Ampelopsis dissecta*.

to mulch all young trees, but where this has not been done, all those that show signs of suffering should be attended to at once. A timely mulching may save the tree. It makes but little difference what material is used so that the soil around the tree is prevented from losing its moisture by evaporation. Stones, if most convenient, will answer as well as anything. If the trunk is fully exposed to the sun, it should be protected from intense heat. A couple of boards tacked together like a trough, and set up against the trunk, will furnish the required shade, or the trunk may be bound with a hay rope, or be loosely strawed up as for winter protection.—T. F.

The Californian Mountain Laurel (*Oreodaphne californica*).—In the north this tree attains a height of from 50 to even 100 feet, though the latter altitude is rare, but in the south 15 to 30 feet is an average size. It is at once one of the most common and beautiful trees in California. The foliage is dense, the wood greyish in colour, very hard, durable, and difficult to split. Both leaves and wood have an aromatic odour, which is strongest in the former. By the slightest friction of the hand it emits

this, but is apt to excite sneezing, and with some people it gives rise to headache. In California, caution is exercised in regard to burning the plant, more especially the leaves, as it is said that a vapour driven off them by the heat is very noxious. It much resembles *Laurus nobilis* in appearance, and is quite as ornamental. It is almost limited to the State of California, not, so far as I have been able to learn, more than crossing the boundary line into Oregon, and goes as far south as Santa Barbara. It is inclined to be a social tree, forming frequently groups of several individuals. It rather prefers the coast, though often found high up in the mountains—hence its common name of "Mountain Laurel." Leaves, oblong-lanceolate, pointed, scarcely acute, reticulately-veined, dark green, lustrous, 4 inches long, 1 inch wide, evergreen; flower, thickly pedunculated, axillary, numerous, involucre; fruit, roundish elliptical, nearly an inch in diameter, when immature green or greenish-yellow, when ripe dark purple—flowering in California from March to April. This very fine evergreen would seem to be quite hardy in mild districts with us; in Mr. Ellacombe's garden at Bitton, there is a handsome bush of it. We have never seen handsomer pyramids of verdure than it forms in a wild state.

The Mexican Plane (*Platanus racemosa*).—This is a tree with smooth white scaly bark, often dividing into several trunks, which diverge widely and irregularly, giving to the tree a straggling and irregular growth. Along river banks, Newberry

mentions that its growth is usually open and symmetrical; but that when it is found in open and high ground, it adopts the general habit of the trees of the country, and spreads out into a wide and compact head. Its trunk will reach 6 feet in diameter, and an altitude of more than 100 feet, with a spread of branches nearly equal to its height, constituting a noble specimen of a tree. It is a tree of a more southern character than most of the trees with which it is associated in California, the centre of its range being probably about the southern boundary of the State. It grows as far north as the Sacramento River, but I have never met it over the Californian boundary line. It is also principally, if not entirely, a tree of the western slope of the Cascades and Sierra Nevadas. It chiefly affects river banks, but, as mentioned, is occasionally found at a higher elevation. Like most of the deciduous trees of California and the dryer portions of North-West America, the wood is very brittle, and travellers encamping under it require to be cautious in case of falling branches, which a fresh breeze will easily bring down upon them. In both habit and character the Mexican Sycamore bears a striking resemblance to the Sycamore of the Atlantic slope (*P. occidentalis*),

Recently Planted Trees and Shrubs in Hot Weather.—

This is a trying time for young trees. Those that were set this spring, and have appeared to be doing well thus far, may succumb to the long continued drought and heat of midsummer. It is safest

and is often considered by unbotanical observers to be the same. It has the same habit, and the same smooth white scaly exfoliating bark; but the bark is whiter, the leaf darker, and the fruit is in racemes of three, instead of being solitary. The leaves are not, except in the young state, pubescent or tomentose, as figured by Nuttall. The dark polished and digitate leaves contrasting with the white bark, give to *P. occidentalis* a more tropical aspect than that of its Pacific congener.—*Horæ Sylvanæ*.

Ailantus glandulosa as a Remedy for Dysentery.—In a recent issue of the *Archives de Médecine Navale* is published an official note, addressed by Dr. Robert, who is the medical chief of the naval division of China and Japan, to the inspector-general of the health service in the French navy, calling attention to a drug used by Chinese physicians in the treatment of dysentery. It consists of the root bark of the *Ailantus glandulosa*, a plant common in the north of China, and less so in Japan. It is also frequently cultivated for the purposes of shade, whilst its leaves have been used as food for silkworms. Dr. Robert sums up by expressing his opinion that the administration of the *Ailantus glandulosa*, as witnessed by him in China and Japan, gave superior results to that of *Ipecacuanha*, astringents, alone or combined with opiates, or calomel.

Wall-plants for Cold districts.—I have a wall 18 inches high on the north-east side of my garden, which I do not wish to raise, as it would be unsightly; but I want a good screen to protect the garden from the north and east winds, which sweep across it with great violence. I should also like this screen to be a very ornamental one, and to present as great a mass and variety of colour as possible. My own idea is to have a wooden trellis, or a trellis of galvanised wire, put up against the wall, rising to the height of 5 feet, and to train on this, not Ivy, or any mere evergreen, because that would be monotonous and wanting in colour, but *Cotoneaster*, or the evergreen *Cratægus*, called *Pyracantha*. With both these plants one would secure an evergreen screen, and also a mass and variety of colour, as each would be covered with white flowers in spring, and with red berries in autumn and winter. Would these plants grow well in such a situation in a cold wet climate in the north of England, and afford the advantages which I wish to secure? Which is the most ornamental for the greatest length of time at the various seasons? and what is the rate of growth of each? Is there any other plant that would be likely to suit my purpose better than these? The situation, though exposed to north and east winds, gets the sun all day.—M. O. D.

The Grass-flowered Mahonia (*M. glumacea*), sometimes called *M. nervosa*, is found wild in Pine woods in the north-west of North America, on the river Columbia, and was introduced in 1822. It is a beautiful little evergreen, which rarely rises higher than from 1 to 2 feet from the ground, and its large pinnate leaves are generally as long as the stems, which, shooting up from the roots, form a tuft-like bush. The flowers are golden-yellow, produced in racemes of about 6 inches long, and are in perfection in March, followed by clusters of deep blue berries, which are ripe in July and August. The uses to which this pretty little shrub may be applied in ornamental gardening are many. It may be planted with the greatest advantage on or near the shady side of rockeries, on the margins of shrubberies or garden clumps, and no plant can supply its place as an edging for walks below trees. It grows best in a cool, peaty, or fibry soil, prefers a shady aspect to a sunny one, and, though perfectly hardy, should always be sheltered from violent winds.—*Gardener*.

The Manzanita (*Arctostaphylos glauca*).—This is a prominent feature in the forests of California and Southern Oregon, forming a dense, clump-like shrub, which grows as high as 12 feet, and nearly as broad as it is high. The trunk divides nearly from the ground into several or many branches, these terminating in a multitude of twigs, so that the shrub is a dense mass of branches and branchlets, all of which are very crooked. The bark is red and smooth, occasionally peeling off, and exposing a new light green bark, which soon turns red. It is everywhere in California, being abundant on the hills and mountains, and extending northward into Oregon. The shrub has a wide range of altitude, growing equally well in the coast valleys, and on the Sierra Nevada Mountains, up to the limit of perpetual snow. The wood is like that of *Arbutus Menziesii*—dense, dark, and dark red in colour, and somewhat resembles that of the Apple tree. I am not aware that any use is made of it in the arts at present, except that rustic seats are fabricated from its crooked and twisted branches. For this purpose it is exceedingly well adapted. The berries have a pleasant acidulous taste, and are often eaten by the Indians and grizzly bears (of which they form the favourite food). As an ornamental shrub, the Manzanita is well worthy of introduction in the parks of England, and, from its hardy constitution, will bear the most severe cold to which

it can be subjected to in this country. Both it and the Madrona I introduced in seed into this country, but whether still growing or not I cannot learn. From experiments tried with the seed in its native country, I find that it soon loses its vitality, and germinates with difficulty.—ROBERT BROWN.

Sambucus Fontenaysii.—This very ornamental, vigorous-growing, and continuously-flowering shrub, was raised by M. Billiard, nurseryman, of Fontenay-aux-Roses, from seeds of *Sambucus californica* (glaucous), which is, no doubt, identical with *S. pubens*. The stem is smooth and covered with a reddish-green shining bark; leaves, of a glaucous green colour, with broadly-oval leaflets, the margins of which are sharply toothed; the flowers, which are disposed in broad corymbs, are reddish when in bud, and of a pale yellow when fully expanded. Like those of the parent plant, *S. californica*, they are produced continuously at the extremities of the shoots which develop themselves during the summer's growth. The plant is exceedingly ornamental, and worthy of introduction into our gardens. M. Carrière considers the parent plant, *S. californica*, to be nothing more than a local American variety of our common Elder.

Dimorphism in the Rose.—A very singular instance of this has recently occurred in a nursery at Lyons, where a specimen of *Rosa polyantha*, a Japanese non-perpetual species, with climbing shoots, and single rose-coloured flowers, bore, in the first place, a number of double flowers, and also produced, from seed, a number of plants, entirely different from the parent. These are all dwarf in habit, and not climbing; some of them, in fact, growing only an inch or two high. Their flowers are mostly double, and of various colours—white, red, and yellow. These varieties will, no doubt, be found useful for covering the bare spaces under specimen shrubs, the surface of flower beds, &c. Too little attention has been given to this accessory embellishment, and many a fine Conifer may be seen in our public and private gardens, the aspect of which would be vastly improved, if the usually naked circle of earth, in which it stands, were gracefully clothed with some sort of verdure.—W. M.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Raising Ground over the Roots of Trees.—Will some of your correspondents kindly favour me with their opinion as regards raising ground round the trunks of Oak trees? Will it hurt the trees to raise the ground round them 3 feet? If it will, what is the best thing to be done?—T. J. G.

Hardiness of *Eucalyptus globulus*.—It is continually asserted that the *Eucalyptus globulus* will not bear more than three or four degrees of frost, but I know instances in which this plant has withstood our winters well; one is near Exeter, where there is a large tree planted twenty-five years ago, and supposed to be the first planted in England; the other was planted in 1869, and though exposed through all winters since that time, it is now growing and doing well. JOHN WATERER, *Bagshot*.

Mock Orange (*Prunus Caroliniana*).—This is a peculiarly graceful low tree, with glossy deep green leaves, and all the branchlets pendulous. In its native country this tree is an evergreen; in our climate deciduous, at least about London. It retains its leaves for a long time, however. There are fair specimens in Kensington Gardens, where, however, they are not easily found, as they are not labelled. The best is just within the Kensington Gate, on the left-hand side.—W.

The Dying Elms on Cheyne Walk.—The improvements which the Thames Embankment has made in this quarter have been attended with disastrous results to some of the fine Elms on Cheyne Walk. At its western end five trees in succession are apparently dead. Near the eastern end too, the trees are in equally bad condition. The rapid decay of these trees, so much to be regretted, is doubtless, with good reason, attributed to the cutting off of the water which formerly refreshed their roots, and to the importation into their immediate vicinity of thousands of tons of dry soil which form the embankment.—W. M.

Ribes sanguineum grandiflorum.—This variety, a seedling from *R. sanguineum*, of which it possesses all the chief characteristics, was raised by M. Danvesse, nurseryman, of Orleans. It flowers very freely, the numerous flowers, which are disposed in very compact clusters, being of a rosy-flesh colour on the outside, and white, or rosy-white, within, somewhat resembling those of *R. albidum*, which is also a variety of *R. sanguineum*. Both are very handsome plants, which, when grown along with *R. sanguineum*, produce a very pleasing effect. Treatment and mode of propagation exactly the same as employed for *R. sanguineum*.

The Dutch Medlar.—It is a mistake to neglect the planting of some of our varieties of fruit trees for their ornamental qualities alone, and among edible fruits few are more worthy of a place among our ornamental trees than the Dutch Medlar. This is the one most commonly grown for its fruit, being the largest, though not the best flavoured variety. It forms large and handsome specimens, with a weeping tendency, and is one of the most desirable of trees for park, lawn, or pleasure ground. Other varieties and species have showy blossoms, and form very ornamental objects, but this is the only one with a tendency to be pendulous.—R.

Siberian Weeping Cherry (*C. chamæcerasus*).—This is a graceful little tree, weeping densely, and with slender twigs. Naturally the species is very dwarf, so that it must be grafted high on a stem to get the effect usually sought after in weeping trees; but it is best suited for a dwarf stem, say 18 to 30 inches, and thus trained, is admirable for high rock-work, banks, or any position where a miniature weeping tree may be desired. A variegated form of this is a pleasing addition; it is spotted or suffused with greenish-lemon, and the variegation does not seem to check the vigour of the tree, as is often the case with variegated subjects. Neat specimens of both kinds may be seen in nurseries for hardy plants, and there is a large specimen in the Crystal Palace grounds.

THE FRUIT GARDEN.

FRUIT SHEDS.

At the request of several correspondents we reprint the following account of this subject from the last volume of *THE GARDEN* (p. 35). They were contributed by Mr. Pearson, of Chilwell, whose recent report on the subject (p. 441) has created so much interest:—Mr. Foster, of Beaton, has, says Mr. Pearson, by chance, hit on the best known plan of growing Apricots. Requiring a shed to back carts under, and to shelter ladders, planks of Oak, &c., he thought, as it would be seen from his garden, that a glass roof would look much better than one covered with slate. He accordingly built one about 100 feet long and 10 feet wide. Posts every 9 feet carry the roof, which is all fixed, no ventilation being required. The south-west side, next the garden, is boarded and painted over with tar, wired,

Portion of Apricot shed.

and planted with dwarf fruit trees, as in the woodcut. Wires are also stretched under the glass, as if for Vines; the distance from the glass being about 1 foot. On the north-east side of the wooden fence, standard Apricots, Plums, and Nectarines are planted, whose heads are trained under the glass, their roots passing under the wooden side into the same border in which those shown growing on the outside are planted. Both ends of the shed are closed in with boards. It is, in fact, a long narrow glass shed open to the north-east, just high enough to back a cart under, but looking from the garden like a double-roofed greenhouse. The trees have been planted three years (this was written in 1871); they have never been syringed, and, in fact, except tying the shoots to the wires and thinning and gathering the fruit, have had hardly any attention. In some parts of the sheds it has been necessary to climb over piles of timber from 4 to 5 feet high to get a good look at the fruit. The result has been

Section of Apricot shed.

extraordinary, and, to me, most unexpected. I should say the trees have been only watered twice since they were planted, and that in the hot summer of 1870. Though I think few would have foreseen such a success through, what may be considered, an accidental discovery, it cannot be thought the less valuable on that account. How loudly it proclaims the advantage of ventilation for Apricots! Does it not equally proclaim, too, the advantage of a dry climate for this tree? What method of growing Apricots can compare with this, either for productiveness or cost of production? The trees are sheltered from frost and wet, and the roots take care of themselves. How different from either the open wall or the orchard-house! No watering, no syringing, no shading! Even good gardeners have been surprised at the result.

THE WEATHER AND THE FRUIT CROPS.

MAY this year has been unusually harsh and severe. The Apricot crop was thinned early, but the warm weather brought out the leaves with a rush, and these protected the later blooms, which have generally set well and, in many situations, promise

a good half and three-quarter crop. Peaches beneath glass copings have withstood the frost well, and are likely to be a fair crop, except in cold and low-lying localities. Plums are very partial; Cherries, as yet, promise well; and Apples and Pears bloomed freely. Early Pears were much cut off in many gardens, and early Apples look suspiciously brown. Court Pendu Plat has only very lately begun to open its flowers; and, as the wind at last has a point of south in it, and the temperature has run up to 68° in the shade, late Apples are now, it is to be hoped, safe. Gooseberries are ruined in many districts, even the largest fruit falling off by wholesale, as if it had been partially roasted. Currants have escaped rather better, though these in places have also been hard hit by the frost. Raspberries have also come safely through in some gardens. Early Strawberries have suffered very much; the early flowers have been blackened in the centre, and some crops have suffered so severely that they have been dug in, and the ground cropped with late Potatoes. The lesson of these late springs is more glass, larger orchard-houses to store away immense numbers of fruit trees in pots until the fruits are set, and the May frosts at an end—after which they could be put out to grow and ripen in the open air. We also want more late flowering varieties of all hardy fruits. Each day taken from the season of flowering renders the probability of a crop the more certain. For instance, as has been stated, early flowering Strawberries have lost their first blossoms, which are mostly the producers of the finest fruit, whereas, Elton Pine and other late varieties are safe. There is, perhaps, less difference in the time of flowering of Pears, Cherries, Plums, &c., than of Apples; but Louise Bonne of Jersey, is often a week or a fortnight before Winter Nelis and Beurré Rance, and it mostly loses its crop in consequence. I wish that raisers of new fruits would earnestly lay this matter to heart, and try to furnish us with races of late flowering and quick-growing varieties. The shorter the season between setting and finishing the better are the chances of fruit in our fickle climate.

D. T. F.

Curious Dimorphism of the Apple.—The last number of the *Revue Horticole* contains a coloured plate and a description of two distinct looking fruit, which were produced last year, on the same shoot of a *Ménagère* Apple tree in the nurseries of M. Durand, at Bourg-la-Reine. The tree was young, and trained as a vertical cordon. One of the fruit in question was of a fine greenish-yellow colour, passing into a rich golden hue on the sunny side, and marked with numerous whitish dots. This fruit exhaled a strong and very agreeable perfume. The other fruit, which grew close beside it, on the other side of the shoot, was a little larger, of a conical shape, and remarkably different in the colouring, which, for about two-thirds from the base up, was of a brilliant red, tinged in some parts with violet, the upper part only being of a greenish-yellow. This fruit, unlike the other, had no perfume whatever. When ripe, both were tasted, when the first was found to have the flavour of a Quince, while the other was harsh and acidulous. Neither could be termed a fruit of good quality, and the circumstance is only worthy of record as an instance of the dimorphism that frequently occurs in the family of the *Rosaceæ*, to which most of our fruit trees belong.—W. M.

Good Advice on Thinning Fruit.—It takes no more time to pick off a little Apple in the summer than it does to pick the same Apple in the fall—and with me the fall is the busiest season of the year. I used to think that thinning fruit was one of the refinements of horticulture which those of us who grow fruit largely for market could not stop to bother with. But a friend's experience convinced me of my error. If there are 2,000 Apples on a tree in the summer, and I let them grow, I have to pick them all in the fall. If this is as many again Apples as the tree ought to bear, the 2,000 Apples would fill, say, five barrels. Now, if I pick off 1,000 of the smallest, and poorest, and specked, and wormy Apples in the summer, the probabilities are that the 1,000 left on the tree would grow so much larger that they would fill the five barrels as before. We pick 2,000 Apples in either case, and get the same amount of fruit. What, then, do we gain? In the first place, the 1,000 Apples do not exhaust the tree as much as the 2,000. There is as much fruit by measure, but it consists largely of material that takes little from the tree or the soil. There is only half as much seed, &c. We ought to thin out at least enough to leave the tree strength enough to bear a full crop the next year. In the second place, the 1,000 Apples are worth much more than the 2,000; and last, but not least, the trees will bear every year. We do not remember to have seen the case stated in a manner more concise or convincing.—*Agriculturist*.

THE GARDEN IN THE HOUSE.

BRITISH FERNS AS TOWN PLANTS.

ALTHOUGH there are no more useful plants in existence for decorative purposes than our hardy British Ferns, yet, singular as it may appear, they are not valued as they should be, except in a cut state. They are the best of all plants for town gardens, in which their graceful fronds keep fresh and green where Geraniums could not exist. Their usefulness in a cut state is admitted, else they would not be brought to market; but it is the common Brake which is selected, a kind which is the least graceful of any. It is, however, their utility in a growing state to which I wish to direct attention. In stands in sitting rooms, even in the darkest streets, they will remain fresh and continue to throw up their cheerful-looking green fronds year after year. Small gardens, too, even though surrounded by high walls, might be made attractive, simply by the introduction of a few Ferns. The great drawback to British Ferns is, they can be bought cheaply, or be had for the trouble of carrying home after a day's ramble among country lanes. In nearly every house the inmates of which are fond of flowers, will be found a Wardian case, or a pan covered by a bell-glass, in which a few exotic Ferns are vainly trying to live and look healthy. Such Ferns receive every attention; their glass covers are now and then removed to give them air, and, yet, in point of freshness and greenness, they cannot be compared with hardy Ferns, which only require a little water to keep them in good health. For small stands, the best suited are *Asplenium Adiantum-nigrum*, *A. marinum*, *A. Trichomanes*, *Blechnum Spicant*, and *Polypodium vulgare*. These are all dwarf kinds which make very effective table-ornaments, if planted in 10-inch seed pans, and if the surface of the soil is covered with fresh wood Moss. Should an ordinary pan not be considered sufficiently ornamental, one of a rustic character, which is generally covered by a bell-glass, may be obtained; those made of virgin Cork are also well adapted for this purpose. For furnishing window-boxes, singly in pots, or large stands, varieties of a more robust growth than those just named, should be chosen, say such kinds as *Athyrium Filix-femina*, *Polystichum aculeatum*, *Lastrea dilatata*, *L. Filix-mas*, *Polystichum angulare*, *Osmunda regalis*, *Scolopendrium vulgare*, and others of a similar character. Large stands of these look well-placed in halls, and are not readily injured by draughts, to which they are subjected. The roots of such Ferns as these, though lifted from a hedge-row, when planted in some London back-yard, push up fronds in spring as fresh as if they had never been disturbed. Most Ferns, in the growing season, require plenty of water, though even on this point they are very accommodating. I have seen plants of *Asplenium Adiantum-nigrum* growing so near the edge of water that their roots have been in it, and I have seen it also on hill sides growing equally well, overhung by rocks, which must have screened it even from rain. Out of all the Ferns just enumerated, the one which revels in dampness more than the others is *Asplenium Trichomanes*. Of this elegant little Fern I have seen some fronds quite a foot in height, when growing near water. One of the most lovely sights possible is a Ferny lane. Last summer I saw one which I shall never forget; it formed a private road to the gate lodge of the house of a friend, and was over a mile in length, the banks on each side being high, and one mass of Ferns and wild flowers. The road itself was very narrow, overhung by trees, which, forming as they did, a leafy tunnel, at least half a mile in length, produced a charming effect. Out of this shady grove I brought some Ferns, which have quite repaid me for my trouble. Amongst hardy kinds the Parsley Fern (*Allosorus crispus*) should not be forgotten. It is dwarf in growth, has bright foliage, and even when planted in a pan has an excellent effect. A few of the Horse-tails, too, when planted in pots, form very graceful plants. Townspeople, who do not find ordinary plants to thrive with them so satisfactorily as they could wish, would do well to take my advice, and import a few Ferns from the country to take their places; were they to do this, I feel confident that they would not be disappointed with the result. In some little London gardens, I have seen Ferns in excellent condition, and, if well attended to, they last good for years.

A. HASSARD.

Upper Norwood.

FOUNTAINS AND FOLIAGE.

THE refreshing aspect of tree-shaded walks, which form such delightful retreats in high summer, is greatly enhanced by the judicious introduction of fountains or cascades. Where well-contrived cascades of a natural character are practicable, they are, perhaps, more desirable in artificial landscapes than fountains, as they may be made to accord more easily with the semi-wild aspect of woods; that is to say, if the intention of the planter has been the creation of certain aspects of the untrimmed grace of natural scenery. The rocky arrangements, by means of which the fall of water is effected, add pleasantly to the picturesque effects of such garden or park scenery, and the general composition being thus combined with the dash and gurgle of the falling waters, is made to produce a sense of coolness at the same time that the unmeasured cadences of one form of Nature's music are pleasingly simulated. But cascades of the kind suggested are rarely practicable in ordinary localities, unless by very costly arrangements; it is, therefore, to fountains, which, if on a moderate scale, are practicable in almost any situation, that the present remarks will be entirely confined.

Fountains, that animate with their soothing plash, and impart a feature of motion, in the shape of glistening shafts, and falling sheets, as of translucent silver, are always attractive during the summer months, especially in wood-shaded retreats. In the glaring sunshine, in openly conspicuous situations, where there is little temptation to linger about their precincts, these garden adjuncts are of far less real value; though it is in such situations that they are generally found, as at the Crystal Palace, the palatial gardens of Versailles, and most of the great public gardens of the Continent. There are, however, exceptions to this general rule, some of which are favourable specimens of artistic aptness for the successful design and placing of a fountain in a woodland scene, and others which are quite the reverse. The first example, illustrative of the foregoing remarks, is represented by the annexed engraving of the magnificent fountain of the Bosquet de l'Arc de Triomphe at Versailles. It is one of the most elaborate and magnificent pieces of fountain-work ever devised. The central portion of the composition is, indeed, elaborately rich in design. The crowning vases, each with its water-plume, and the lateral falls of foaming water over a series of richly-carved marble tazzas in the form of gigantic cockle-shells, flanked on either side by an unsupported single jet, form the least part of this highly-wrought composition, the central portion being that on which the chief labours of the architect, sculptor, and hydraulic engineer have been lavished. It is composed of an entablature, a cornice, and a façade of four richly-embellished pilasters, between which are three niches, each ensconcing an elaborately sculptured vase, standing upon a suitably enriched pedestal, in front of each of which is a marble basin, equally sumptuous in decorative carvings; the whole of these features being made subservient to the display of rising or falling waters, the whole masses of which eventually shimmer down in glassy sheets over a series of marble steps into a basin of the same material. These features form the chief part of the composition, which is a real triumph of that kind of art; and yet it was not enough for the florid tastes of the Le Notres, and Mansards, and Le Pautres of the day. Additions of a splendid character were yet to be made, which consisted of two elaborately perforated pyramids of most intricate design and enrichment, devised in such a manner as should fit them to exhibit a jet of water rising to their very summits within the prison bars of their marble frame-work. This is surely an example of utter extravagance, and, indeed, of outrageous excess in garden fountain work. A costly gew-gaw, of which even the tasteless king (to gratify whose caprice the monster fountain was constructed), devoted, as he was, to meretricious and costly display, must have tired of in a week. It is just the sort of thing to see once—say at the Crystal Palace, mingling with fireworks, or in the transformation scene of a pantomime—and to exclaim, on its successful production, how very magnificent! What a gorgeous design! and then, the momentary surprise being over, never caring to see it again. As a permanent object to be placed in a "bosquet," that is to say, a sylvan wilderness, it is simply an over-done piece of tawdry splen-

FOUNTAIN OF THE BOSQUET DE L'ARC DE TRIOMPHE.

dour, only redeemed from positive vulgarity by its grand dimensions, its ingenuity of device, and its costly material. Viewing the "bosquet" in question as a cool summer retreat, let the reader place his hand over the great mass of masonry, marble, and water-display, so as just to leave in view the simple fountain in the distance, with its single jet and dripping tazza, and I fancy that he will be of my opinion, that the more simple and unpretending form of fountain amalgamates far more soothingly with the scene, while the greater structure disturbs the repose of the grateful shade, both with its noise and its obtrusive, garish grandeur. The fountain in the gardens of the Horticultural Society is another example of a highly wrought work of that class being an uncomfortable excrescence, rather than an ornament, however good it may be in itself. In landscape-gardening, and even in semi-architectural gardening (if that combination may be called gardening at all), nothing is more difficult and requires more care and artistic judgment than the introduction of fountains, which, far more often than otherwise, serve to spoil the combinations which they are intended to embellish.

H. N. H.

FRAGRANT WOODS.

THE properties and uses of woods are various; some are sought for their beauty and utility for the cabinet-maker or pianoforte manufacturer, some for their adaptability for carving or engraving on, others for their colouring properties, and some for their medicinal uses. There are a few, however, which have the rare attraction of being fragrant and odorous, and hence are valued for small special fancy articles for ladies' use, or for the purposes of the perfumer, who distils pleasant scents from them. The study and consideration of woods may be influenced by many causes, according to the purposes to which they are to be applied. The cabinet-maker will group them according to the disposition of their colours and the direction of their fibres, and will sometimes also take into consideration the odour, which is an essential point in the eyes of the perfumer. Two or three are tolerably well known, such as Camphor, Sandal, and Cedar woods; others have not been so generally described. Although fragrant odours are very generally diffused over the vegetable kingdom, yet they are not often centred in the woody fibre of the plants. We know these odours well in flowers, and we find them strongly diffused in many aromatic leaves, as those of the Lemon and Citronelle Grasses, and of the Faham Orchid (*Angræcum fragrans*), and of *Eucalyptus citriodora* and *E. odorata*. Sometimes the pleasant odour or pungent flavour is concentrated in the seeds and seed-vessels, as in the Nutmeg, the Tonquin-bean (*Dipterix odorata*), the Musk-seed (*Abelmoschus moschatus*), the odoriferous seeds of *Ayden-dron* (Nees.), the Vanilla pods, and those of *Myospermum* *pythoxylum*, of South America. In several trees the aromatic principle is strongest in the barks, as in Cassia and Cinnamon, the Sassafras of Tasmania, *Atherosperma moschata*, and *Croton Casca-* *la* and *Eleutheria*, of the Bahamas. Essential oils are obtained from many of these. The bark of *Ocotea aromatica*, from New Caledonia, possesses a strong Sassafras flavour, and there is a fragrant bark yielded by the *Alyxia aromatica* of Java and Cochin China. The *Joffea* (*Ixora*) *odorata* of Tahiti has a close and fragrant wood. In Tasmania and Australia we have the Musk-wood (*Eurybia argophylla*) with timber of a pleasant fragrance and a beautiful mottled colour, well adapted for turnery, cabinet-work, and perfumery purposes. The native Box-wood (*Bursaria spinosa*, Cav.) has also a pleasant but fleeting scent. The Scent-wood of the same island (*Alyxia buxifolia*, R. Br.) has an odour similar to that of the Tonquin-bean. It is but a straggling sea-side shrub of 3 to 5 inches in diameter, and consequently does not produce wood of any size, but it is fine and close-grained, of a lightish brown mottled appearance. In the colony of Western Australia we have the Raspberry-jam-wood, of a species of *Eucalyptus*, which derives its popular name from the similarity of the scent to that preserve. It is a handsome wood, well fitted for cabinet purposes. Many of the Australian woods exhibit a peculiar beauty of structure, which adapts them for small furniture and turnery uses. Some are highly fragrant, and retain their agreeable odour for a considerable period of time; this renders them additionally pleasant and acceptable in the form of ornamental articles for the boudoir and drawing-room. The scented Myall (*Acacia homalophylla*) is a very hard and heavy wood, having an intense and delightful smell of Violets. It has a dark and beautiful "hardening," which makes it applicable to numerous purposes of the cabinet-maker and the wood-turner, and an infinite variety of minor uses. It rarely exceeds a foot in diameter, but has been used as veneers. This tree is common in

many parts of Australia. Since the London Exhibition of 1862, when caskets and other articles were shown from Queensland, and the remarkable property it possessed became generally known to European manufacturers, the wood has been in request for making glove, handkerchief, and other fancy boxes. As long as it remains unpolished it preserves this peculiar fragrance of Violets, which does not occur with such perfection in any other known substance. The desert Sandarac Pine (*Callitris verrucosa*) is a tree of moderate size, from the vicinity of the River Murray, seldom attaining to more than 18 inches in diameter. It has a peculiar odour, from which it is sometimes called Camphor-wood, and it is said to be obnoxious to the attacks of insects. The dark beauty of its wood makes it useful for many articles of small cabinet furniture. The mountain Sandarac Pine, another species, similar to the preceding, is available for identical uses.

The Sassafras tree (*Atherosperma moschata*) has an aromatic bark, which yields an essential oil, resembling the Sassafras oil of America, with an admixture of oil of Carraways. The timber, which is useful to the cabinet-maker, has a dark "hardening," and frequently exhibits a pleasant figure; it has also the quality of taking a beautiful polish. Sassafras wood (*Sassafras officinale*), which is brought over from North America in billets, is highly aromatic, both in smell and taste, owing to a yellow volatile oil it contains. As this repels insects, the wood is used in India for the interior work of trunks, drawers, boxes, &c. Brazilian Sassafras is the aromatic bark of *Nectandra cymbarum* (Nees.) The fragrant bark of the swamp Sassafras of the United States (*Magnolia glauca*) is greatly sought for by beavers, and hence is often called Beaver-wood. A common deception is much practised in the streets of London in selling artificially-scented woods and roots which have been steeped in citronelle and other pleasant essential oils.

Sandal-Woods.

The Sandal-wood of commerce is the product of various trees belonging to the genus *Santalum*, and the species called *S. album* for a long time furnished the principal supply. Being a hard, close-grained, and ornamental wood, it is used for some descriptions of cabinet work and various carved, ornamental, and useful articles, such as writing-desks, work-boxes, card-cases, &c., are made of it. But its chief characteristic consists in the remarkable smell of the wood, which it owes to the presence of a peculiar volatile oil, extensively used by the natives of India as a perfume. This, also, has caused it to be largely used as incense to burn in the temples of China. In course of time Sandal-wood was discovered to be abundant in some of the South Sea Islands, where it is the product of several species of *Santalum*, different from the long-known Indian one. There are about ten species of the genus, which are chiefly restricted to the East Indies, Australia, and Oceania. The Indian species are *S. album* and *S. myrtifolium*. The former is a small tree, from 20 to 25 feet high, which is found on the border of Wynaad, in the Peninsula, and in Mysore. The exports of the wood from Madras to Bombay, Bengal, Pegu, and the Persian Gulf are considerable. The wood is burnt to perfume temples and dwelling-houses. The same tree yields both the white and the yellow Sandal-wood, the last being the inner part of the tree, and is very hard and fragrant, especially near the root. The Mahomedans procure a precious oil from the moist yellow part of the wood, which they value as a perfume. Large shipments of it are made to Bombay, Bengal, and the Persian Gulf. The tree grows in the island of Sandal, Timor, Rotti, Savii, Sumba, Bali, and in the eastern part of Java, in the arid soil of the lower regions. The wood, which in its colour and texture resembles Box-wood, is much sought for as an article of commerce by the Chinese, who use the sawdust for making rings and pastiles for burning, as, during combustion, it exhales an agreeable odour. Mixed with some chemical preparation, the sawdust is often used in scent-bags, which hang as charms to the women's dresses. The imports of Sandal-wood into Chinese ports have, however, of late years almost ceased. While, in 1862 and 1863 from 7,500 to 8,000 piculs (1¼ cwt.) of Sandal-wood, valued at about £14,000, were imported into Canton, within the last four or five years the imports have ceased altogether. In Europe Sandal-wood is chiefly used for carving and turning. In the India Museum, Whitehall, various specimens of the ornamental application of Sandal-wood in the East may be seen in boxes inlaid with ivory, a handsome carved Sandal-wood table from Bombay, and other objects. The Australian species of Sandal-wood are believed to be derived from *S. lanceolatum*, *oblongatum*, *obtusifolium*, *ovatum*, and *venosum*. The tree is found in Queensland and Western Australia. At the London International Exhibition of 1862 a fine log of Sandal-wood, weighing 4½ cwt., was shown from Blackwood River, Western Australia; and another, 3 feet 6 inches long by 11 inches diameter, from York. It is of an inferior quality as regards odour. In

1849 as much as 1,204 tons of Sandal-wood, valued at £10,711, were shipped from Western Australia. The merchants bought it for shipment at £6 to £6 10s. a ton. The Sandal tree of any size within a radius of 150 miles of Perth have now been cut down, and little can be obtained. It is probable that there are several distinct species of the tree in the South Sea Islands which have yet to be botanically determined. The tree is not found on all the islands of the Pacific; its head-quarters would appear to be among those of the south-western portion, including New Caledonia, the Loyalty Islands, New Hebrides, Espirito Santo, and some others. In the Fiji Islands, which have produced several thousand tons within the last thirty years, the tree has also become scarce. It is only the central portion of the tree which produces the scented yellow wood constituting the Sandal-wood of commerce. The trunk and larger branches are cut into lengths of from 3 to 6 feet, and the whole of the bark and outer white wood are chipped off with the axe—an operation technically called “cleaning.” Thus, a log 1 foot in diameter is reduced to a billet only from 4 to 6 inches thick. The quality of the wood depends on the quantity of the oil contained in it, as indicated by the smell when freshly cut or burned. The old trees produce the best, and in them that part of the wood near the root is the most prized. A handful of the shavings of the wood will prevent moths from attacking clothes of any description; and the same means may be used to keep away insects from specimens of natural history. Owing to a similar strong aromatic odour, furniture made of the fragrant timber of the bastard Sandal-wood of Australia (*Erimophila Mitchelii*, Benth.) may be free from the attacks of insects. The wood is hard, of a brown colour, nicely waved, and beautifully grained. It will turn out handsome veneers for the cabinet-maker. *S. Austro-Caledonicum* (Viell.) of New Caledonia, furnishes a superior kind of Sandal-wood to that of other countries, owing to the strength and fineness of its odour. It is to be regretted, however, that this tree is being ruthlessly destroyed in the island, as the wood is of such great use in perfumery. Scarcely anything but the stumps and roots left from former trees can now be utilised. An essential oil, distilled in England and France from Sandal-wood, fetches £3 per pound. Powdered wood, for filling sachets and other uses, is sold at 1s. per pound. The Pacific species of Sandal-wood are *S. ellipticum* and *S. Freycinetianum* (Gaudichaud), which are met with in the Sandwich Islands. The latter species is found in the high mountainous ranges of Tahiti; but the wood is of inferior quality, as it is not odoriferous, or only becomes so by age. The wood of *Myoporum tenuifolium* (Forster) is sometimes used as a substitute for Sandal-wood; the fragrance of the fresh wood is very pleasant, but it soon loses its odour, after being kept sometime.

The Cedar-wood chiefly imported is *Cedrela odorata*, from Cuba, Mexico, and Central America, in quantities varying from 3,000 to 5,000 tons yearly, and the red or pencil Cedar of Virginia and Bermuda, *Juniperus virginiana*. Fragrant cedrine, an essential oil, is distilled from the wood. The Cedar-wood of British Guiana (*Icica altissima*, Aubl.) has also a strong aromatic odour which keeps away insects, and adapts it for cabinets, wardrobes, &c.

An undefined rare wood from South America, called Paosanto (probably the *Kielmeyera* of St. Hilaire), has a fine odour, which it never loses. It takes a magnificent polish, is of a green colour, very solid, and elastic. It may be used for furniture, wind instruments, and would make magnificent pianos. A log brought down the river to Parana some years ago measured 27 feet in length, with a section of 17 inches square. The Violet-wood of British Guiana, or *Andira violacea*, derives its specific name more from its colour than its scent. In Japan they cut up the wood of a small tree, called Camaboc, largely for making toothpicks, which is of itself quite a trade in that country. The bark has a peculiar and pleasant aromatic flavour. A small portion of the bark is allowed to remain on each toothpick. All the Japanese use them regularly after every meal.

Camphor-wood.

The Camphor-wood boxes, brought from China and the East, are well known for their strong preservative odour, and are found useful in keeping away moths from woollens and furs. The China and Japan Camphor-tree belongs to the Laurel family, but that of Sumatra and Borneo is the *Dryobalanops camphora*. Even the leaves and fruit smell of camphor. In Sumatra this tree is abundantly met with on the west coast, chiefly in the extensive bush, but seldom in places more than 1,000 feet above the level of the sea. The tree is straight, extraordinarily tall, and has a gigantic crown, which often overtops the whole woody giants by 100 feet or so. The stem is sometimes 20 feet thick. The Barus camphor of this island is the most esteemed of any, and it is for this drug, obtained in but small quantities—seldom more than half a pound to a tree—that it is ruthlessly destroyed. The tree, when felled, is divided into small pieces, and these are afterwards split; upon which the

camphor, which is found in hollows or crevices in the body of the tree, and, above all, in knots or swellings of branches from the trunks, becomes visible in the form of granules or grains. An essential oil also exudes from the tree in cutting, which is sometimes collected, but is scarcely remunerative. On the west coast of Formosa there are forests of Camphor-wood, and a great deal of crude camphor is shipped thence to Amoy and other Chinese ports. Large quantities of the wood are sawn into planks. Tables and cabinets are then made of it, and it is also turned into platters and washing basins. Only a small portion of the vast Camphor forests of Formosa has been reclaimed from its wild inhabitants, and this consists of fine tall trees, the growth of ages. When a tree is felled, the finest part of the wood is sawn into planks, the rest chopped small and boiled down for the Camphor. Camphor-wood (*D. camphora*) grows in abundance in the mountains of Santerborg, Marang, Sunda, and Surgony Water, Borneo. Its girth reaches 17 or 18 feet, and the stem often attains the height of 90 or 100 feet to the first branches. The wood contains a quantity of oil, is tough, durable, and, owing to its strong-scent, withstands the attacks of the worm, so destructive in those seas. Hence it is much valued for ship-building. It takes metal fastenings well from being oily, and iron has been found not so liable to rust in it.

An essential oil of Roses, from some undefined wood, called *Aspalathum*, is distilled in France and Germany, and sells at about £3 the pound. There is a wood which comes from French Guiana, called there *Bois de Rose femelle*, believed to be the produce of *Licaria odorata* which has a delicious odour approaching to Bergamot; but being extremely fugitive, it is necessary to pulverise the wood at the moment of distillation. The essence drawn from it is now employed by the Parisian perfumers. It is a coarse-grained, yellow-wood, and scarcely ornamental enough to be sought for cabinet-work. The *Lignum Aloes*, Calambak, or Eagle-wood of commerce, is of all perfumes that most esteemed by Oriental nations. The trees from which it is obtained are not well defined. The best is supposed to be from *Aloexylon agallochum* (Lour.), of Cochin China; while the *Aquilaria ovata* (Cav.), and *A. agallocha* (Roxb.), of tropical Asia, furnish, it is believed, other kinds of Aloe-wood. All are highly fragrant and aromatic, and are occasionally used by cabinet-makers, and inlayers. *Aquilaria agallocha* (Roxb.), is a medium-sized tree, growing in Borneo, Sumatra, and Java, in the high regions. The wood is compact, of a yellow colour streaked with black. By rubbing, however, it only gives forth an odour of Rhubarb, which is also palpable in slicing the wood. The most esteemed kinds of this wood are obtained from the mountainous countries of Cambodia and Cochin China, to the east of the Gulf of Siam. It is the decaying old heart-wood which is burnt for perfume. Some specimens of odoriferous wood passing under the name of *Lignum Aloes* were a few years ago imported from the coast of Mexico, and believed to be the produce of a species of *Bursera*. Incense wood is the fragrant product of *Icica guianensis*. In conclusion it may be added that, while some woods attract by their pleasant odour, others are so fetid and obnoxious that they have obtained the appropriate name of “stink woods.” Of this we have an example in the Stink-wood of the Cape of Good Hope (*Oreodaphne bullata*), which has a very disagreeable smell when first cut; hence its vernacular name. The brown-coloured wood is durable, takes a good polish, resembles Walnut, and might probably be employed for cabinets for natural history collections, as it is not infested by insects. The foregoing paper is from the pen of Mr. P. L. Simmonds, and appeared some time ago in the *Art Journal*. It contains so much interesting information that we have deemed it worth while, in the interest of our readers, to reproduce it at length.

The Pop-corn Trade of Chicago.—Here now is a native industry which has been quietly making a gigantic growth, if an increase of 6,000 per cent. in a year can be considered gigantic. What effect it may have upon the settlement of the great West, or upon the civilisation of the East, remains to be seen. We allude to the Pop-corn business, as carried on in Chicago. The raw material is raised upon the broad Burr Oak openings of Wisconsin; the finished product is consumed by the juveniles of Chicago, and the profits realised go to add to the magnificence of the metropolis of the West. The *modus operandi* is simple. The Corn, inclosed in a wire gauze pan, is held for a few moments over a clear fire; then a noise as of a miniature musketry ensues, and each kernel, as it snaps and pops, turns inside out with a large increase of volume. The starchy granules are burst by the heat, and swell until the hitherto insignificant grain becomes as large as a Hickory Nut.—*New York Tribune*. [Pop-corn is a small variety of Maize, which is very extensively used in America, and which forms, when prepared as above described, a pleasant substitute for biscuits. It deserves to become popular in all countries.—ED.]

THE INDOOR GARDEN.

CHAMÆDOREA KARWINSKIANA.

ALL the species of the genus *Chamædorea*, about forty in number, nearly half of which have been introduced into cultivation, are natives of America, some being found in Columbia, but the greater number in Mexico. They grow from 6 to over 12 feet in height, and have straight, smooth, annulated, or ringed, stems, somewhat like those of the Bamboos, marked with scars left from fallen leaf-stalks. The leaves are borne on the upper part of the stem, and are sometimes entire, but, more frequently pinnate, with segments varying in width. The inflorescence is developed from the axils of the lower leaves, and is generally accompanied by a more or less persistent spathe. The flowers are small and insignificant. The species (*C. Karwinskiana*), of which we give an illustration, is a native of Mexico, and grows to the height of from 6 to 10 feet. It produces five or six annulated stems, each crowned with five or six leaves, from $2\frac{1}{2}$ to over 3 feet long, with from sixteen to twenty-two lance-shaped pointed divisions, of a lively green colour. The sheaths of the younger leaves are thickly covered with a whitish meal or powder. It requires the heat of a temperate house, and should be potted in light soil, which must be kept continually moist. It may be multiplied either from seed or by separation of the shoots which spring from the base of the stems. These should be potted and placed under a bell-glass in heat, where they should remain until they have taken good root. W. M.

HOW I TREAT LISIANTHUS RUSSELLIANUS.

As this fine Mexican plant seems, now-a-days, to be set aside as uncultivable, and, as I have been able to grow and flower it in perfection, perhaps the following account of my mode of treatment may not be undesirable. I first fill a 6-inch pot half full of potsherds, over which I place 1 inch of Sphagnum; I then fill the pot within an inch of the top with rich light sandy soil. When all is pressed down equally and firmly, and a smooth surface is made with the bottom of a small pot, I sow the seed early in spring, and cover it very slightly with dry white sand. I then cover the pots with bell-glasses, and place them on a shelf in a shady part of an early Vinery, keeping the surface constantly moist by pouring water on the outside of the glasses. As soon as the plants have come up, air is admitted, and increased as they advance in growth. When sufficiently strong, they are pricked out into small pots, having the same drainage, Moss, and mixture as the seed-pots, and are again shaded with hand or bell-glasses until the plants have become established. In three weeks or a month's time they require to be potted off singly into small pots; and I encourage their growth as much as possible by placing them in a shady part of either a Vinery or Melon-pit, whichever is kept at the highest temperature, with a humid atmosphere. As soon as they begin to fill their pots with roots, I give them a little clear manure-water once a week. I re-pot for winter about the middle of August, using pots according to the size of the plants, and replace them in the same growing tempera-

ture as before, until the pots are filled with roots. After this, I begin to prepare the plants for winter by giving them less moisture, more air, and a cooler temperature; and, finally, they are placed on a shelf near the glass, in the coolest part of the stove, and wintered in a rather dry state. Early in February I begin to increase the heat and moisture, and, as soon as they begin to grow freely, I re-pot them, an operation which is generally performed about the second week in March. They receive another shift in April, and those intended for large specimens are again shifted in May into 18 or 20-inch pots, using a mixture of equal quantities of strong maiden loam, peat-mould, burnt clay, leaf-soil, and cow manure, to which is added a little white sand. In potting, I use a large quantity of drainage. I give very little water till the roots have reached the sides of the pots, when it is increased as the plants and the season advance, giving heat and moisture in proportion. I stop the young shoots immediately above the second joint, as soon as they are sufficiently advanced to

permit that operation to be performed. Each shoot then produces four, and they require stopping about three times. The last stopping for plants required to bloom early should take place in the first week in June, and for plants required to bloom later in the first week in July. As they advance in growth, I tie out the branches in order that I may have well-formed plants. When growing freely, they are sometimes attacked with a disease at the base—the result of a moist confined temperature. To prevent this, I allow the surface to become dry once a week or so, during which time the plants are supplied with moisture from the pans in which the pots are placed for a few hours, being careful not to allow any stagnant water to remain about them. As soon as the blooms begin to expand, the atmosphere is kept drier, and more air and light are admitted. This mode of growing the *Lisianthus* is the same as that practised by the late Mr. Green, under whose direction I once was placed, and the results in my case have been equally as good as those obtained by that excellent cultivator. My plants, when fully grown, are about $2\frac{1}{2}$ feet high and as much through, and bear abundance of flowers, the beauty of which is the admiration of all who see them. Most people lose

their plants while quite young through over-watering; and I confess there is some difficulty in getting them established, but, if the directions just given are strictly followed, success will be almost certain. T.

ECHEVERIAS.

THIS interesting genus of succulent plants was founded in 1828 by De Candolle, and named by him in honour of Echeveri, a distinguished Mexican flower-painter. The greater number of the species are natives of Mexico, although the genus is distributed from California to Peru, and a few doubtful species are ascribed to Japan and Abyssinia. In their native habitats, they are found growing in dry positions fully exposed to the sun, on rocks, mountains, and elevated table-lands. They delight in a dry warm atmosphere, and a light soil rich in humus or decayed vegetable matter. They somewhat resemble the

Chamædorea Karwinskiana.

Sempervivums in their general appearance, but are usually of larger growth, and the leaves are disposed in looser rosettes of irregular shape. They are often glaucous and, sometimes, exhibit pleasing metallic reflections. The following is a very comprehensive enumeration of the known reputed species, arranged in alphabetical order:—

E. abyssinica (Hort.).—Introduced into England from Abyssinia by Major Leveson. It is, probably, a species of *Cotyledon*, but very like the *Echeveria* in its habit and rosettes of leaves. It is announced in this year's catalogue of M. L. de Smet, nurseryman, of Ghent, who also calls it *E. sempervivoides*, adding that, during the summer, its leaves are entirely brown. Flowers, red.

E. acutifolia (Lindl.).—A rather large-growing species, allied to *E. gibbiflora*, with spatulate, or spoon-shaped, acute leaves and flowers in a dense panicle. Discovered by Hartweg, in Mexico.

E. adunca (Baker), (*Pachyphytum roseum*, Hort.).—A handsome plant, attaining a height of 4 feet in a temperate house. The leaves are olive-shaped, and are covered with a light white mealy powder; the flowers are striking, the petals being yellow and red, the calyx red and green; while at the base of each flower there is a conspicuous red bract. The inflorescence is disposed in a simple unilateral cluster. Native of Mexico.

E. agavoides (Lem.).—This handsome and very distinct species, which was introduced about 1860-61, resembles an *Aloe* in habit, forming a small dense rosette of spiny-pointed glaucous leaves, of a greenish opal colour, and margined with red, at least on the upper part; the flowers are insignificant in appearance, but valuable for the sake of producing seed, the plant being re-produced with difficulty in any other way. Native of Mexico.

E. argentea (Hort.).—Probably a garden name for *E. pulverulenta*.

E. atropurpurea (Baker), (*E. sanguinea*, Hort.).—A very handsome large-growing species. Stem, a few inches high; leaves, oboval-acute, glaucous, deep red, especially on the upper surface; flowers, white at the base, red above; calyx, green, regular in shape; inflorescence, in a simple and regular cluster. Probably a native of Mexico. An excellent subject for the centre of small circular beds of white-foliaged plants in summer.

E. Bernhardiana (Forst.).—According to Mr. Baker, this is a form of *E. gibbiflora*.

E. bifida (Schlch.).—This plant is only known from the description of it given by Schlechtendahl, in his work on the plants brought from Mexico by Schiede and Ehrenberg. It appears to be closely allied to *E. secunda*, but bears its flowers in a two-cleft cluster.

E. bracteolata (Lk.).—This species, which is a native of Caracas and the Andes of New Granada, has quite a different appearance from that of the Mexican species. The stem is tall, and the leaves are green and distant from each other; the flowers are yellowish, and are produced in a two-cleft unilateral cluster.

E. bracteosa (Paxt.), (*Pachyphytum bracteosum*, Lk.).—A handsome species, introduced from Mexico in 1838. The leaves are large, tongue-shaped, and of a handsome glaucous-green colour; the flowers are of a yellow and red colour, and are more curious than handsome in appearance; the divisions of the calyx being very broad, and exceeding the corolla in length.

E. caespitosa (D. C.).—A small stemless species, from California and Mexico, with narrow green leaves in a rosette; flowers, yellow, in a compact cyme. This species is difficult to cultivate, and does not rank amongst the finer kinds.

E. californica (Baker).—A small stemless species, with narrow glaucous leaves; flowers, yellow, arranged in a unilateral cyme. Native of California. A handsome and easily-grown species. There is a variety (*E. c. viridis*) which has green leaves.

E. calophana (Hort. ang.).—Probably a garden name for *E. acutifolia*.

E. campanulata (Kuze).—A Mexican species, identical with *E. caespitosa*, according to Mr. Baker. Leaves, glaucous underneath, and margined with rose-colour.

E. canaliculata (Hook.).—A handsome and robust-growing caulescent species, with long strap-shaped channelled leaves, narrowed at the point, green, with brownish reflections, and arranged in a rosette. Flowers, red, in a handsome cluster. Native of Mexico, and introduced by Mr. Staines, an amateur at Kew.

× **E. carinata** (Hort.).—Said to be a hybrid between *E. metallica* and *E. atropurpurea*. M. L. de Smet announces a form of it which he has named *Gandavensis*, and which he describes as a magnificent variety.

E. carnicolor (Bak.).—A handsome stemless species, belonging to the same section as *peruviana* and *lurida*, forming a small rosette of glaucous and reddish leaves, with small clusters of fine red flowers. Native of Mexico.

E. coccinea (D. C.).—An old-fashioned caulescent species, intro-

duced from Mexico in 1816, closely allied to *E. pubescens*, but with narrower leaves, covered with a finer pubescence. The flowers, which are of a saffron-tinted red, are disposed in a dense spike.

E. Corderoyi (Bak.).—Nearly allied to *E. agavoides*, but forming a large rosette of sixty to seventy leaves. Flowers, fifteen to twenty in number, arranged in a trichotomous cyme.

E. cymosa (Lem.).—A stemless species, with long attenuate leaves, which are at first glaucous, and ultimately green. Flower yellow, in a dense cyme. Native of Mexico, and also, it is said, California. The plant grows slowly, and perishes if exposed to moisture.

E. decipiens (Baker).—This is not properly an *Echeveria*, as the plant has all the appearance of a *Sedum*, while it resembles an *Umbilicus* in its corymb of white flowers. Mr. Baker considers it native of Peru, while M. L. de Smet, in his recent catalogue, puts it down as coming from Port Natal. When in flower the plant stands about 8 inches high.

E. Desmetiana.—This species is thus described in a letter from M. L. de Smet:—"The finest of all the *Echeverias* is, undoubtedly, *E. Desmetiana*, a native of the higher mountains of Mexico. Imagine a specimen of *E. agavoides*, with shorter and more numerous leaves overlapping each other, like the petals of a Rose, and of a fine blue colour. This will only give you a feeble notion of this new introduction. Unfortunately, as I have not succeeded in multiplying the plant, I do not know when I shall be able to distribute it."

E. discolor (L. de Smet).—Leaves, red underneath, in a compact rosette; flowers, large, of a very deep orange colour. Native of Mexico.

E. farinosa (Lindl.).—A pretty dwarf species, from Carmel Bay, California, forming a rosette of leaves covered with a white mealy powder; the flowers are yellow, and disposed in cymes like those of a *Sempervivum*. This plant is very impatient of water applied either to its leaves or to its roots.

E. farinulenta (Lem.).—A name given by Lemain to a species not mentioned by any other author.

E. fulgens (Lem.).—See *E. retusa* of Lindley, further on.

E. gibbiflora (D. C.).—This is the largest species of the genus and the most extensively grown in plant-houses. It is a native of Mexico, and has been known for about fifty years. The stem is 1 or 2 feet high, and nearly 2 inches thick. The leaves, which are disposed in a rosette, are large, thick, wedge-shaped, mucronate, flat, glaucous, and, more or less, exhibiting metallic reflections. The flowers are pitcher-shaped, red and yellow, disposed in a large panicle of scorpioid cymes. This plant is highly valued on account of its flowers, which are produced in great abundance all through the winter, and last for a considerable time. There are several varieties of it, of which the most remarkable is—

Var. metallica (Baker).—This is remarkable for its iridescent foliage, which presents the metallic hues of some pigeons' neck feathers, that is, rose-colour, with a play of copper-coloured and bronze reflections. The inflorescence, also, is very fine during the heats of summer. The plant forms an admirable subject for the centres of circular flower-beds containing plants with variegated foliage. Like most of the *Echeverias*, it dreads moisture, especially if stagnant, and a single ill-advised watering will sometimes kill it immediately. It requires a light well-drained soil, rich in humus. In winter it should be removed into a temperate house, and kept in a dry atmosphere. Three sub-varieties have been distinguished by florists, viz., *metallica grandis*, *m. lucida*, and *m. crispata* (Baker). The leaves of these are very broad, and some are undulated on the margin.

E. glauca (Baker).—A dwarf stemless species, with glaucous wedge-shaped leaves, terminating in a small red spine; flowers, red and yellow, in a small, short, simple, unilateral cluster. This charming species is now much used for summer edgings to mosaic beds of succulents, and other fine-foliaged plants. It thrives in the full sun. In winter, it should be removed to a temperate house, and placed in a well-lighted position, and in a dry atmosphere. The catalogue of M. L. de Smet contains two forms of this plant—viz., *E. glauca metallica* and *E. glauca roseo-cincta*.

× **E. glauco-metallica** (Veitch).—Said to be a hybrid between the two kinds whose names it bears. It is very largely used for summer edgings and mosaic patterns.

E. globosa (Hort.).—This garden variety, named in catalogue as a synonym of *E. rosacea*, appears to be a variety of *E. glauca*, and is employed for the same purposes.

E. gracillima (Muhlpl.).—A variety of *E. secunda*, with slender leaves.

E. grandiflora (How).—A synonym for *E. gibbiflora*.

E. grandis (Hort.).—A variety of *E. gibbiflora*.

E. Grayii (Baker).—A synonym for *E. paniculata* (Gray).

E. Greeni (Cat. L. de Smet).—A slender erect plant, the leaves of which, in shape and arrangement, resemble those of a *Portulaca*.

but are three times as large. Native of Port Natal. This plant presents a very singular habit for an *Echeveria*.

E. Hookeri (Lem.).—*Dioslostemon Hookeri*, Salm Dyck.

E. lanceolata (Nutt.).—Native of California. Flowers in a panicle. Referred by Mr. Baker to *E. Cæspitosa*.

E. laxa.—A Californian species, with yellow flowers, 1847 (Paxt. "Bot. Dict.")

E. linguæfolia (Lem.), (*Pachyphytum Lingua*, Hort.).—A small Mexican species, of no horticultural value.

E. lurida (Lindl.).—A stemless species, with a compact rosette of narrow, channelled, glaucous leaves, tinged with purple or brown. Flowers, handsome, red, in a simple cluster. Mr. Baker refers this species to *E. racemosa* of Schlechtendahl. It should be grown in light sandy soil in the dry atmosphere of a warm house, and should receive no water in winter.

× *E. luteo-gigantea* (Hort.).—A hybrid between *E. retusa* and *E. macrophylla*, raised by M. Rendatler, nurseryman, at Nancy.

E. macrophylla (Hort.).

E. metallica (Hort.—see *E. gibbiflora*).

E. misteca (Cat. L. de Smet, 1874).—A dwarf plant, with leaves 1.10th inch long, terminated by a red mucro or point.

E. mucronata (Schech.).—This stemless species was observed in Mexico by C. Ehrenberg, but it does not appear to have been introduced into our gardens.

E. navicularis (Cat. L. de Smet, 1874).

E. navicularis, var. *rubra* (Cat. L. de Smet, 1874).

E. nodulosa (Baker).—A small Mexican caulescent species, with green leaves, edged with a red margin, forming a rosette. Flowers, in a simple cluster.

E. nuda (Baker).—A small caulescent species, sent from Mexico by Botteri. Leaves, rather distant from each other, slightly reddish at the ends; flowers, in a cluster, of a bright red colour; petals united for a considerable distance.

E. Pachyphytum (Baker).—See *E. bracteosa*.

E. Pachyphytioides.—"A splendid hybrid between *Pachyphytum bracteosum* and *Echeveria metallica*. The leaves are coloured like those of the latter species, and resemble those of the former in shape, but are two or three times as large." Cat. L. de Smet, 1874.

E. paniculata (S. Gray), (*E. Grayii*, Baker).—A North Mexican species, with flowers in a panicle.

E. peruviana (Meyen).—A stemless species, from the Cordilleras de Tacna, Peru; leaves, very glaucous, in a dense rosette; flowers in a simple cluster. Does not appear to be in cultivation.

E. Pfersdorffii (Hort.).—A small garden variety of unknown origin, with green leaves.

× *E. pruinosa*.—A hybrid between *E. linguæfolia* and *E. coccinea*. Cat. W. Bull, 1874.

E. pubescens (Schlech.).—A caulescent species, covered all over with a soft pubescence; flowers, of a fine red colour, in a simple spike.

E. pulverulenta (Nutt.).—A Southern Californian species, with a stem 8 to 12 inches high, surmounted by a rosette, 12 to 16 inches in diameter, of large, longish, pointed leaves, covered with a white powdery efflorescence. The effect of the plant, when well-grown, is that of a work of art in massive silver.

E. pumila (Lem.).—This species resembles *E. glauca* and *E. secunda*, but is much smaller than the last-named, and more finely glaucous. It forms handsome small rosettes, of closely-set, narrow, longish, glaucous leaves; flowers, in a unilateral cluster. A good plant for flower-beds in summer. Requires a temperate house with a dry atmosphere in winter.

E. quitensis (Lindl.).—An insignificant species from the Andes of New Grenada. The leaves are not disposed in rosettes, but are distant from each other, and green in colour; flowers, in a cluster.

E. racemosa (Schlech. et Cham.).—Leaves, 6 to 8 inches long, in a rosette, deep green edged with pale buff; flowers, in a simple cluster. According to Mr. Baker, this species should be referred to *E. lurida*, although the name *racemosa* has, we believe, priority in date.

E. reflexa crispa (Cat. L. de Smet, 1874).—A Mexican species, with leaves 4 inches long, glaucous, edged with red, and undulated; flowers, large, numerous, of an orange-yellow, and appearing early in the season.

E. retusa (Lindl.).—A caulescent species, from the mountains near Anganguco, in Mexico; leaves, ten to fifteen in number, glaucous obtuse, and sometimes notched at the end, arranged in a rosette. Flowers, very handsome, coral-red, unilaterally disposed in a two-cleft cluster. This species is very much prized for its handsome flowers, which are produced all through the winter, provided it is properly grown in a warm and dry house in good vegetable soil. *E. fulgens* of Lemain does not differ from the present species. The following hybrids have been obtained from *E. retusa*:—× *Floribunda splen-*

dens, raised by M. Rendatler, of Nancy. × *Mincata*; same source. × *Retusa glauca*, hybrid from *E. retusa* and *E. glauca* (Cat. W. Bull, 1874).

E. rosacea (?) (Linden and André).—A stemless garden variety, with a regular rosette 4 to 6 inches across of glaucous leaves. It is also known in gardens as *E. globosa*. It is nearly allied to *E. secunda*, and also very much resembles *E. glauca* and *E. pumila*, of Baker. It is largely grown for forming ornamental edgings.

E. rosea (Lindl.), (*Cotyledon roseata*, Baker).—A Mexican species, which has received the name of *rosea* from its rose-coloured bracts. The flowers are yellow, and the plant, which is caulescent, has not the appearance of a true *Echeveria*. Mr. Baker thinks the specific name should be changed as there already exists the Siberian *Cotyledon rosea* of Lessing.

E. sanguinea (Hort.).—See *E. atropurpurea* (Baker), *supra*.

× *E. scaphylla* (Deleuil).—This plant was first noticed in the *Belgique Horticole*, when M. Deleuil, of Marseilles, stated that it is a hybrid between *E. agavoides* and *E. linguæfolia*. From the description and figure given it appears to resemble *E. secunda*, and is a handsome-looking plant, with a stemless, well-furnished rosette of leaves, and a good subject for ornamental edgings.

E. Scheerii (Lindl.).—A Mexican large caulescent species, introduced into the Royal Gardens, Kew, about 1842 by Mr. Fr. Scheer. Leaves, oval-acute, narrowed into a foot-stalk, of a silvery-white colour, and arranged in rosettes.

E. secunda (Lindl.).—A charming stemless species, introduced from Mexico, about 1837. The leaves are disposed in small and regularly-formed rosettes, resembling those of a *Sempervivum* with glaucous and diverging leaves. Flowers in a small, simple, unilateral cluster. This is a distinct species, and much used in forming ornamental edgings. The following varieties are also cultivated: viz. —Var. *glauca* (*Revue Horticole*, 1869, p. 229).—Forms rosettes 2 to 4 inches across. Var. *glauca major* (Cat. W. Bull, 1874). Var. *pumila*.—Rosettes of smaller size.

E. spatulata (Cat. W. Bull, 1874).

E. spatulifolia (Cat. L. de Smet, 1874). A small caulescent species, quite smooth, of a grass-green colour; leaves, oboval, distant, obtuse, spreading. It has no resemblance to an *Echeveria*, but it is very like a *Crassula*.

E. Sprucei (Baker).—A species found in the Andes of Ecuador, by Dr. Spruce.

E. stolonifera (Baker).—A small Mexican species, with handsome flowers, and green leaves, shining on both sides. It is remarkable for producing numerous runners or suckers. Introduced by Mr. W. Saunders, about 1865. Requires a dry and warm temperature.

E. strictiflora (A. Gray).—A species found in the mountains of Texas; not in cultivation.

E. subspicata (Baker).—A caulescent smooth species, closely allied to *E. coccinea*. Native of mountains in Columbia, near the snow-line.

E. subulifolia (Baker).—Mr. Baker thus names *E. teretifolia* of De Candolle, as Thunberg had already described a *Cotyledon teretifolia* from the Cape of Good Hope.

E. teretifolia (D. C.).—A synonym for *E. subulifolia* (Baker). Flowers, unilaterally arranged in a two-cleft cluster.

× *E. tortuosa* (Hort.).—A garden variety, known only by name.

E. undulata (Cat. L. de Smet, 1874).—Said to be a hybrid between *E. atro-purpurea* and *E. metallica*.

E. Van Celsti (Cat. L. de Smet, 1874).

E. Verolietii (Hort.).—A garden variety, known only by name.

E. villosa (Cat. L. de Smet, 1874).

E. yuccoides (Hort.).—Perhaps the same as *E. agavoides* of Lemaire.

General Remarks on *Echeverias*.

None of these plants (says Prof. Morren, in the *Belgique Horticole*, from which the present article is translated) are able to endure even a slight degree of frost, and, when used out of doors, they should never be put out before the middle of May, nor left out after the third or fourth week in September. During winter they require a well lighted and moderately warm house. They succumb at once to cold and stagnant humidity. They thrive best in a rich light soil, the most suitable compost being a mixture of vegetable mould, peath or heath soil, free loam, and sand, thoroughly well drained. They are multiplied by using the leaves as cuttings, or from cuttings of the stems, or from seed; and, in some cases, from the suckers which are sent up from the base of the plant. The following useful directions on this subject were published last year in the *Revue Horticole*, by M. J. B. Weber, head gardener in the botanic garden at Dijon:—"Echeverias are very easily multiplied. When a large number of plants is not required, they are propagated either from cuttings of the flower-stems or from the suckers at the base, when they are produced. These are much to be preferred to

cuttings of the flower-stems, as they form plants which maintain a compact low habit for a longer time. The cuttings or suckers should be laid by for some days on a dry shelf until they have become cicatrised, and then they should be planted out in a temperate house. If, on the other hand, a large number of plants is required, it is best to cut off the leaves at the base, laying them by to become cicatrised, like the cuttings, and then planting them obliquely in pots, merely inserting the base of the leaf into the soil. Roots will soon be thrown out, and, before long, the young plants will appear." The soil should be a light sandy mixture, such as has been already described, and the leaves or cuttings should be sparingly watered until they have taken root. As soon as they have rooted well it is best to re-pot them in a mixture of leaf-mould or well-rotted manure and loam, with about one-fifth part sand. It is best to keep young plants within doors for the first season, as they are generally too small and weak during that time to make any very effective display out of doors.

M. Bazin, of Clermont (Oise), has described his successful mode of propagating these plants, in the *Horticulteur Français* of 1854, as follows:—"Many authors say that Echeverias are propagated by means of stem-cuttings and from the suckers which are emitted from the base of the plants. For many years, during which I have grown these plants, I have never seen any of these suckers; and, as for stem-cuttings, when these are made, the plant must be sacrificed, that is, the entire head of a plant must be cut off in order to furnish the cuttings. My mode of propagation is very different, and does not involve the sacrifice of a single plant. It is as follows:—I first pot the plant in a small pot, so that it may become pot-bound; this, however, does not prevent it from flowering. I allow the flower-stem to lose its flowers and dry up naturally; after the flowers have fallen, the sap, still continuing to flow to the extremity of the flower-stem, causes a small rosette of leaves to be produced there. When these are formed, I cut off the flower-stem and make cuttings of the extremities, which I plant in small pots filled with heath soil. In two years time, I have plants flowering to perfection, and the old plant from which the cuttings were taken, having been removed into a larger pot, is still splendidly vigorous and unimpaired. In this way I propagate as many Echeverias as I wish, without any sacrifice and without any difficulty."

How to Grow Lapagerias.—No one should think of growing the beautiful Lapageria in a pot. Plant it out in a border by all means, and let its roots go where they like for nourishment. Treated in this way, it will grow well, and soon fill a whole house. Be it either the white or the red variety, no matter, give it room. It is, undoubtedly, the most ornamental climber that the conservatory can boast of. It is clean-growing, and not, like many other climbers, liable to bug and scale. Thrips, and even spider, will attack it; but wash it well with the syringe, and no danger need be feared. Anyone who has it in a pot should turn it out at once; and, if there be no conservatory border, let it have a tub of good loamy earth, and it will succeed, sending up growth after growth, to the delight of the cultivator. Those who have seen the corridor at Messrs. Veitch's, with the bells of the white Lapageria suspended from its roof, need not be told that it is even more valuable than the red form.—*Farmer.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Fuchsia corymbiflora.—Several plants of this Peruvian species, trained as standards nearly 6 feet high, are now in flower in the large temperate house at Kew. This species has leaves nearly as large as one's hand and bears terminal clusters of crimson flowers, each fully 3 inches in length. It is a plant well worth growing indoors.—J. H. S.

Sonchus multibracteatus.—This is now in flower in the succulent house at Kew, and like its congener, *S. laciniatus*, it has cut or finely-lobed foliage of a fresh green colour, the mid-rib being hairy at the base, and its flowers are borne in terminal clusters, each being rather larger than a shilling and of a bright lilac-purple colour. It is one of the few "Sow Thistles" worth growing for its flowers.—B.

Dictyopsis Thunbergii.—This does remarkably well planted out in the border of a little greenhouse. In habit it somewhat resembles *Myrsiphyllum asparagoides*, but the leaves are much larger, and, if possible, of a brighter and fresher green tint. It grows vigorously in a moist border of sandy loam. Its flowers are small, of a pea-green colour, and rather sweetly scented. It comes from the south of Africa, and is well-deserving of cultivation, either in pots or planted out.

Arundo conspicua as an Indoor plant.—Grown in pots in a cool greenhouse or winter garden, this noble Reed forms a striking object, and its silky plumes last in perfection much longer than when produced out of doors. It likes a strong fibrous loamy soil, and a plentiful supply of water nearly all the year round. I have had a plant of it in a large pot in our conservatory for over two years, and it is just now throwing up feathery plumes in abundance, and these, unless broken or cut, will last until young ones are again produced. Last autumn I had this plant for several weeks in my front hall, and it was much admired by all who saw it. It was placed immediately in front of some heavy crimson hangings and its silvery sprays stood out clear and bright, thus forming a novel and pleasing natural indoor ornament.—J. H. S.

A NEW KIND OF LABEL.

Most people are familiar with the many different kinds of labels that have from time to time been introduced. Wood, iron, zinc, porcelain, glass, and other substances, have all been tried, and now whalebone has been added. This last, which has been named the Elastic label or tally, has been found efficient, and to possess the following advantages, viz., cheapness, being made out of the rib of any old umbrella; simplicity, for any one can make them; durability, for, if the ring (or cap) is made just sufficiently tight to move easily, they are weather-proof and water-proof; neatness, because they are unobtrusive; and ease in reading the name, as, from the elasticity of the material, the split opens so wide that it is unnecessary to take the label out of the soil. For ordinary purposes neither ring nor cap is needed; as, when the split is not too long, it closes of itself sufficiently to keep the label dry, or if the split is long enough to allow of its being partially inserted into the soil, the pressure of the earth holds the parts close together. The portion of the label on which the name is written or printed is affixed with bookbinder's paste, the paste being rubbed on the side of the split intended to receive it, and the label (unpasted) attached; then, by pressing the parts together or tightening the ring, complete union is effected. No danger exists of the split parts sticking together from the protruding paste, as the

Whalebone Labels.

elasticity of the whalebone prevents that from happening. The sides of the split parts are better left as torn apart, as, from the unevenness, the pressure acts more effectively, and the label is more firmly fixed. R. R.

DISCOVERY OF A NEW MEDICINAL PLANT.

In the forests of Brazil a plant, as important as the Cinchona itself, has just been brought to light by the intelligence and perseverance of Dr. Coutinho, a Portuguese physician. The plant and its qualities have long been known to more than one of the native tribes, but their medicine men have hitherto kept their knowledge a profound secret. Dr. Coutinho, however, having once heard of its extraordinary properties, and secured safe evidence that they were not overstated, allowed no opportunity to pass without endeavouring to gain something like positive knowledge of the nature of the plant, and the localities in which it was found. At length he succeeded in obtaining a specimen of "the great medicine plant," as it was called, and tested its efficacy. Its chief property was said to consist in its power to produce most copious perspiration, for which purpose it was administered in fevers, and was said to be almost a certain specific. Having proved that copious perspiration ensued almost immediately after a single dose, Dr. Coutinho considered its importance established, and forwarded a specimen to the well-known pharmaceutical chemist, M. Rabuteau, of Paris, under its native name of Jaborandi. The results of M. Rabuteau's analysis and

experiments, published in the scientific journal, *L'Union Pharmaceutique*, are to the following effect:—He discovered, by careful analysis, that Jaborandi contained no alkaloid; and the eventual residuum, which was of a brown colour, proved perfectly tasteless. So far the experiment was unsatisfactory. But, as he states, he determined to make an infusion of some leaves, and, thinking himself the fittest person to make a first experiment on, took a dose, covering himself with a blanket, and, lying down calmly, awaited the result. After about a quarter-of-an-hour, drops of perspiration began to exude about the temples and forehead, and eventually the perspiration became general and profuse. No unpleasant symptom of any kind supervened, neither of prostration or nausea; and, after changing his wringing wet linen, M. Rabuteau went to bed, and slept calmly and soundly till morning, awaking with a pleasant sensation of refreshment, and, feeling convinced, as he unhesitatingly states, that a new and most valuable medicine had been added to the range of medical knowledge—a medicine which he thinks scarcely, if at all, less important than Quinine itself. It is still uncertain, in consequence of the specimens received consisting only of leaves, to what class of plants this new febrifuge belongs, whether to the Peppers, or to one of some two or three other families of plants that have been suggested. M. Rabuteau found that the leaves had a slight peppery taste which may have suggested the Pepper tribe as that to which the plant belonged.

THE FLOWER MISSION.

[The practice of taking flowers to the sick in hospitals, tenements, houses, &c., is spreading in American cities. The following verses accompany a fine page illustration of the subject, which recently appeared in *Harper's Weekly*.]

Into the homes of sorrow and distress
The rare sweet flowers go to bud and bloom,
And with their own bright life make glad awhile
The lives that wither in perpetual gloom.
Poor hearts that long have starved for word of love,
Dim eyes that ne'er behold a beauteous thing,
And tired hands that stretch themselves in vain
For joys that ever from their grasp take wing:

To these the flowers on their mission go,
And breathe a fragrance fraught with new sweet life,
And cause an atmosphere of joy and peace
To enter e'en 'mid scenes of pain and strife.
Sweet buds of beauty! how they seem to say,
"Cheer up! cheer up! there are kind hearts and true,
And though your paths seem overgrown with thorns,
Yet there are flowers still which bloom for you!"

A thousand blessings on the kindly hands
Which pluck the fragrant flowers for the poor!
A thousand blessings on the kindly feet
Which falter not, but go from door to door,
And leave with tender, loving charity
The sweet joy-breathing gifts of love divine.
Who knows what endless flowers of grace and truth
The Flower Mission may hereafter twine?

A Remarkable Manure.—The following testimony to the virtues of a patent manure was recently received by its owner:—"Dear Sir,—The land composing my farm had hitherto been so poor that a Scotchman could not get a living off it, and so stony that we had to slice our Potatoes and plant them edgewise; but, hearing of your manure, I put some on a ten-acre field surrounded by a railroad fence, and in the morning I found that the rock had entirely disappeared, a neat stone wall encircled the field, and the rails were split into fire-wood, and piled up systematically in my back-yard."

Packing Plants.—Plants always travel better by being sent upright in round baskets, with sticks and mats round them; no system invented up to the present is equal to this, but it is the most expensive. All delicate-leaved plants, such as variegated Pelargoniums, suffer by the foliage being broken and otherwise disfigured by other modes of package. The next best system is a good box, and the plants laid down and all spaces filled up with moss or small savings, and as many plants turned out of pots, consistent with safety, and put in sugar paper. This is a capital way of sending such things as tender Zonals, &c.; more common things, as bedding plants, &c., are laid down with their roots wrapped up in paper to keep them together. By this means the weight of the pots is saved, a great quantity can be packed in a small space and at a small expense, and the carriage cost is but trifling to any part.—H. CANNELL.

WORK FOR THE WEEK.

The Flower Garden and Pleasure Grounds.

THE weather hitherto has been most exceptional in character, as regards cold and drought. "Cassella's Registering Thermometer" fell to 32°, or the freezing point, on the night of the 7th; to 31° on the night of the 10th; and to 26°, or 6° of frost, on the night of the 12th inst. Ice, of considerable thickness, has been formed; and the foliage of Potatoes has again been blackened. Recently turned-out bedding-plants, of the most tender species, have, however, suffered less than might have been expected. What rain we have had has been exceedingly partial. In many gardens, the planting of flower-beds has, on account of the unfavourableness of the weather, been delayed to an unusually late period; and, even in cases where the planting has been accomplished some time since, little or no progress has as yet been made by the plants, and incessant watering has been absolutely necessary to keep them alive. In ordinary seasons, it is always advisable to give the beds a thorough soaking at least twice a week, until the plants become somewhat established; but this season it has been found necessary to sprinkle the plants every evening, an operation which has always a tendency to cake, or render the surface of the soil hard; and, on this account, mulching is very desirable wherever that is practicable. Peg down the shoots of all plants which are large enough to admit of that being done, so as to prevent them from being blown about and broken. Pick off the blooms of Pelargoniums and other bedding plants for some time to come, in order to strengthen the plants as much as possible. Stake up Carnations, Picotees, and other plants which may require that attention; and attend carefully to Roses, which are, in many instances, suffering severely from the ravages of the rose maggot, as well as from aphides. The maggots must be picked carefully off and destroyed, while the aphides should be washed off with the garden engine. To render this operation effectual, however, a person should precede the engine, and, with his fingers wetted with tobacco-water (which he should carry with him in a small watering-pot), examine the young shoots and unexpanded flower-buds, and crush the insect pests on them as much as possible, without injuring the shoots or foliage. The engine, which should be put in operation immediately afterwards, should be charged with the coldest water which can be procured; and this, vigorously applied, will wash the crushed and discomfited aphides from their stronghold before they have time to recover themselves. It is quite necessary, at the present time, to free Rose-trees of everything in the form of insects, if at all possible, as they will very soon be in full flower, when syringing cannot well be practised without serious injury to the blooms. Any trees or shrubs which may have been recently transplanted, and which may show indications of suffering from the effects of the long-continued drought, should, in addition to frequent and liberal supplies of water and mulching at the roots, be syringed so as to thoroughly wet the foliage—late in the evenings of hot dry days. Let hardy Ferns, in the root or rock-garden, be well supplied with water while dry weather continues, or the fronds of many will become a prey to red spider, which will seriously impair their beauty during the remainder of the season. The dry weather which we are experiencing will, to some extent, obviate the necessity of so frequently mowing lawns and Grass borders as would otherwise have been needed; straggling tufts and bents will, however, here and there, present themselves, and these should be occasionally cut down with a scythe. Lawns, in many gardens, are already quite brown; this, however, may always be prevented where there is an unlimited supply of water, as an occasional flooding with a hose, or otherwise, will always keep the Grass green.—P. GRIEVE, *Culford, Bury St. Edmund's*.

Hardy Flowers.

Herbaceous and Alpine plants, being now at their best, will require some attention. Vigorous-growing perennials will need staking—an operation which will have to be extended, in some cases, to annuals and biennials, the blooms of many of which are now very attractive. The surface of beds and borders should be occasionally stirred by means of a hoe. Double Rockets, which have bloomed profusely this season, should have their shoots layered—an operation which will soon induce the production of shoots in abundance; and these, when they have attained a length of 2 or 3 inches, may be taken off and made into cuttings. Pyrethrums for late blooming, if cut down and allowed to grow afresh, will come into bloom during the later summer months. Hardy perennials generally, which bear division, may still be multiplied in that way; and, where that is not applicable, cuttings should be inserted as soon as possible, in order to ensure their becoming well established before winter. Hardy annuals for late blooming should be sown in shady spots, to be transplanted hereafter to the positions in which they are to flower. Seeds of Brompton, Emperor, and Queen Stocks should also now be sown for flowering next spring. Continue to prick off perennials as soon as they are ready for

removal. Plants in pots will require plenty of water at this season; and specimens of such plants as Phloxes, Pæonias, Pyrethrums, &c., will need attention in the way of staking and removing dead blooms. If not already done, lose no time in plunging the stock of plants in store-pots in wood-ashes or sand. Conspicuous amongst hardy plants now in bloom may be mentioned various kinds of Iris, particularly the different forms of Spanish and English Iris, and the tall-growing and handsome *I. ochroleuca*. Lilies, too, of various kinds have commenced flowering, the most attractive, at present, being some forms of *Lilium Thunbergii* and the yellow Martagon. I have likewise noticed the rare *L. Szovitzianum* producing its richly-scented yellow flowers in several gardens abundantly. Larkspurs of various sorts are also in bloom; and the tree-Lupine (*Lupinus arboreus*), a valuable plant for planting against a south wall or in warm shrubberies, is now one mass of yellow inflorescence. *Baptisia australis*, a handsome blue-flowered leguminous plant, is now very attractive; as are also several species of *Astragalus*, such as *purpureus* and *Onobrychis*. The different varieties of the tree-Pæony, now in flower, are very ornamental, and a good display is produced by Bell-flowers, Pentstemons, Alliums, Sweet Williams, Pinks, &c. In many places, too, the blooms of various hardy aquatics, such as the Water Violet, are conspicuous. The blooms of this plant, which are of a pale lilac colour, with a yellow eye, are arranged in whorls on a spike often a foot or more in length, and are very effective. I recently observed the Ethiopian Lily producing its well-known white spathes in abundance in the lake at Battersea, where it has, I believe, remained for the past three or four seasons uninjured, and has bloomed annually. Some ornamental Grasses also look well in the open garden at this season, notably *Poa fertilis*, a graceful-habited species, which forms a dense tuft of slender leaves, surmounted by airy panicles of purplish flowers. It is a capital plant, either for border decoration or for isolation on turf—a position in which a good specimen of this Grass may now be seen just within the principal entrance to the Botanic Gardens at Kew.—T. SPANSWICK.

Cool Orchids.

If the weather continues hot, ventilation may be allowed, in the case of the cooler-growing species, both night and day, and during the hottest part of the day all the ventilation possible should be given, in order to keep the thermometer down to as near 60° as possible, for it is a well-known fact that many *Odontogloss* and *Disa* are often injured by a high summer temperature, more than by a very low one during the dull winter months. Plenty of water should now be used, the stages and floors should be damped two or three times daily, and many of the plants, such as *Cypripediums*, *Disa grandiflora*, *Masdevallias*, and newly imported *Odontogloss*, will be all the better for regular syringings once or twice daily. Keep a sharp look-out for all insect pests. Thrips, greenfly, and red spider, are now very busy, and soon do an enormous amount of mischief, unless speedily exterminated. Regularly sponging the plants with clean tepid water is one of the very best preventives of insect pests, and the plants always look fresh and clean after such an operation; if fumigation is resorted to in the case of aphides, care must be taken not to allow the fumes to become too hot, or the foliage of *Odontogloss* and *Miltonias* will be sure to curl and fall off in a very short time. Top-dressing may still be proceeded with, using newly-gathered Sphagnum, which should be kept moist with the syringe so as to induce it to grow freely. The following, amongst other Orchids, are now in bloom, and should be removed to the driest and coolest end of the house, viz.: *Odontoglossum Alexandræ*, *Masdevallia Harryana*, *Veitchii*, *igneæ* *Lindenii*, *Ochthoides*, *Nycterinia*, and *Polyantha*. *Nasonia cinnabarina* is also in flower, and is one of the smallest of all Orchids, a good established plant being only about 2 inches high. *Disa grandiflora* now throwing up its flower-spikes will require a copious supply of water at the root. Imported *Odontogloss* should be simply laid on a bed of living Sphagnum and syringed occasionally until they form growth and roots.—F. W. BURBIDGE.

Indoor Plant Department.

Conservatory climbers require more attention at this season than at any other. Fuchsias trained on rafters should have their shoots thinned, and the borders in which they grow occasionally watered with manure-water. Where *Clianthus Dampieri* is in bloom, the greatest care must be taken in watering it; some raise the soil a little around the neck of the plant, so as to prevent its getting wet; others feed with water from saucers placed under the pot. Seed-pods on Azaleas are removed as soon as they appear; the latest-flowered ones should be re-potted, if necessary, and placed in well-shaded Vineries. Camellias, Orange trees, &c., should be still kept in warm well-shaded houses, and syringed early every afternoon. Pelargoniums, as they advance in growth, should be staked and brought into the conservatory. In stoves, a little weak manure-water

should be given now and then to *Caladiums*, which should also be kept well shaded and in a nice moist temperature. The first-flowered *Gloxinias* and *Achimenes* are now about over, and should be placed on back shelves in warm houses, water being partially withheld. Such as are in flower should be kept near the glass, shaded from sudden outbursts of bright sunshine, and the foliage kept dry. They should also be brought into cool or intermediate houses to prolong their beauty. Keep *Gardenias* well watered, syringed, and shaded. *Aristolochias* and a few other stove creepers, apt to harbour mealy bug, should be occasionally syringed with weak tobacco water, which will clear them of that pest. Similar applications are also effectual in preserving the young shoots of *Diospyros*, *Medinillas*, *Cyanophyllums*, &c. *Cycas*, *Encephalartos*, and other plants of that class should be frequently examined, in order to liberate and keep in proper order the young fronds that become entangled with other plants with which they are associated. Give liberal supplies of water to Orchids, but no more shading in dull weather than is absolutely necessary, unless it be to prolong the beauty of their flowers. *Calanthes*, which are growing strongly, should be kept on shelves near the glass. Filmy Ferns, which enjoy a steady temperature under hand-lights, should be kept in the darkest parts of the Fernery, and receive extra shade. The glasses under which they are kept should be rubbed dry with a cloth, and the plants should every evening be gently watered through a fine rose or syringe.

Indoor Fruit Department.

Suckers of the earliest of the Queen Pines which are now colouring should be taken off, potted, and plunged in front of the beds. Where tan or other fermenting material, is used, the beds should be either wholly or partially renewed before the next successions are introduced, and as the heat begins to decline. Where Fungi make their appearance in the beds a little fresh air-slaked lime should be mixed with the fermenting material. Inside Vine borders should, occasionally, receive thorough waterings, and waterings of weak manure should be given to those in pots. A little air is necessary, both night and day, when the Grapes are colouring, and also a little fire-heat. Peaches and Nectarines that are ripening should receive a steady gentle heat, and air should be given them on every favourable opportunity. The syringe should be freely used in the case of late crops; thinning and tying in the shoots should also receive attention. Strawberries in full bearing should occupy the top shelves on the back walls of Vineries and early Peach houses; the next in succession having set their fruit should be kept in cooler houses, and the last crops for the season's forcing should be placed outside in front of walls with a north aspect, or on the sides of shady walks. French Beans producing crops in early Vineries, should be kept near the glass, but not in close proximity to the pipes, as that induces red spider.

Pits and Frames.

These are now nearly cleared of bedding plants, and, as sufficient time has not yet been spared to re-fill them, *Alternantheras* and *Coleuses* still under cover should be, therefore, allowed more room. *Dracaenas*, variegated *Abutilons*, &c., should be still retained in frames; but early-flowered *Calceolarias*, when turned out of the conservatory, if good, should likewise be placed in frames to ripen seed. If desirable to retain some of the best of them for next year, the flower-spikes should be cut off, and the plants placed in frames in front of those kept for seed. Plants of *Amarantus salicifolius*, as they advance in growth, should be re-potted, placed in rather close cold pits, and encouraged by weak applications of manure-water. Single and double *Petunias* should be trained into form, and not allowed to bloom until they have attained the required dimensions. Japan Lilies, as they form their flower-buds, should be removed from pits to larger houses, then top-dressed with decayed cow-dung and turfy loam in equal proportions, and securely staked. Plants of *Erythrina Crista-galli*, as they make sufficient growth to require stakes, should be removed from pits to larger structures.

Hardy Fruit Garden.

Modern horticulturists have not only learned, but have endeavoured to practise the great lesson of the husbanding of force. In the olden times growth was made to be cut away. Now, wise cultivators lead it from the first into channels of usefulness. Hence the greater attention devoted to summer pruning than used to be the case; indeed, properly practised, it is almost the only pruning that is needed; for there is no reason why a single shoot should be grown in summer more than will be wanted to fully furnish or enlarge the tree next spring; that is if the tree is in a perfect state. At times, a useless shoot may be allowed to remain, as a stimulant to sickly roots, or as a mode of creating more roots, and stronger than those that already exist. But, assuming that root force and top growth are

fairly balanced, then all useless growth is wanton waste; therefore, the great aim of summer-pruning should be to reserve sufficient food for fruit bearing and furnishing, and no more. Such pruning can hardly be too gradual and slow. Begin by getting rid of any weak, diseased, and ill-placed shoots, if possible. Then go on selecting for removal other shoots—if one at a time on a branch so much the better—until all superfluous wood is removed. In hardly any process is so much evil wrought by hastiness as in the summer pruning of hardy fruit trees. A process that ought to be spread over the growing season is often, for want of thought and time, concentrated into one or more wood slaughterings, often inducing, in the case of Peaches, Nectarines, and Apricots, the production of gum and stunted growth. Were it not on account of late frosts, I would advise beginning summer pruning so early that a knife would never be needed. The safest summer pruning consists in making it wholly a case of disbanding; but the frosts come too late for this method, and render it dangerous to prune much, or at all, till June; there is, therefore, the need of more care, lest evil should arise from the diversion of so much sap into new channels; and the best mode of meeting the difficulty is to proceed only with a few shoots at a time. Simultaneously with pruning, the fruit should be thinned. Nothing is gained, but a great deal lost, by leaving too many. It is difficult to lay down rules, so much depends on the strength of the trees, the character of the soil, and the object of the cultivator. For Peaches and Nectarines, a fruit on every 6 inches of space may be accepted as a good average, fine fruits are expected. Many leave them much closer, and some commend 9 inches or 1 foot apart. It is a bad plan to leave the fruit in clusters, so that they cannot swell without crushing each other out of shape, or go against a branch or a nail that is likely to mar their form or pierce their substance. Misshapen fruits are not fit for table, and those that are pierced are sure to rot before they are ripe. Attention to these trifles now will tell most satisfactorily at gathering time. Unless the crop is very scant indeed, each malformed awkwardly-placed fruit should be removed at once. This is of less consequence in the case of Apricots, as they are mostly used for preserving; and squeezed fruits are generally the highest valued.—D. T. FISH.

Kitchen Garden.

Mulching, hoeing, watering, and shading should receive careful attention during the continuance of the present dry weather. Amongst established crops the more vigorously the hoe is kept going the less necessity there will be for watering; but, where the latter is to be done it should be done thoroughly, or not at all. Occasional surface waterings do more harm than good, by encouraging, during the temporary supply of moisture, the formation of surface roots, which are destined to perish almost the moment the supply of moisture is withheld; whilst, if the plants had been left to themselves, with an occasional stirring of the surface, they would have their roots deeply into the land, and have drawn their supply of moisture from a stratum less influenced by extremes of heat and light. I do not wish to say a word against irrigation, where it can be done thoroughly, but I believe a good deal of time and labour is spent in dry seasons in watering, from which no appreciable result is obtained. Deep culture and fairly liberal dressings of manure are the only safeguards against drought. Now that bedding plants removed from pits and frames, have the latter cleared out and tewedashed, preparatory to filling them with fermenting material; this should be managed so as to produce a steady mild heat that will last for a month or so, in order to give the plants a start. Cucumbers, Melons, Capsicums, and Green Ginger for preserving, will do very well in such pits now, but as the latter will grow at least 3 feet high, sufficient space should be left for the proper development of the plants. Cucumbers and Melons succeed well in such pits, if the proper varieties are selected; thus affording an opportunity for painting and painting the Cucumber-houses, ready for the reception of the autumn crop in September. The main crop of Broccoli, &c., should now, or shortly, be put out. In all gardens in which the land is required to produce to its utmost extent, it is a good plan to plant Broccoli between the rows of early and second early potatoes; one row of Broccoli to every two rows of Potatoes. Thus, if the rows of Potatoes are planted 2 feet apart the Broccoli will be 4 feet apart; and, by Christmas, it will be found that the Broccoli will have pretty well covered the ground. I have followed this plan some years, and I am satisfied with the result. It is also, in planting late Broccoli not to plant all of it in one row; and, in order to prolong the season till Cauliflowers come in, a few might even be planted under a north wall, which, in the event of a severe winter setting in, will, probably, pass through the ordeal with the least injury. On the morning of the 13th inst. the thermometer here fell to 31°, and this unusually low temperature was accompanied by a keen biting north wind, which must, had it continued a short time longer, have arrested growth.—E. HOBDAV.

SOILS AND FERTILISERS.

THE SEWAGE QUESTION FROM A CHEMICAL POINT OF VIEW.

THIS subject was brought before the Chemical Society the other day in the form of a lecture, by Dr. Corfield. The removal of the refuse from towns, said Dr. Corfield, and especially excretal matter from the neighbourhood of habitations, was one of the most important sanitary problems of the day, the general death-rate at any place being in inverse proportion to the efficiency of the means used for this purpose. He would warn people that he considered the immediate removal of excretal matters of the highest importance, since the retention of these matters near habitations for a longer or shorter period was always certain to be attended with evil consequences. All the various systems for treating sewage might be reduced to two classes:—(1) Those in which the whole of the refuse matter was removed with the foul water; (2) those where this foul water was allowed to run into the sewers, but as much of the solid matter as possible was kept back. In judging of the respective merits of these two classes in all their varieties, chemistry comes to our aid, and shows that, where midden-pits or cesspools are used, the water of the wells in the neighbourhood becomes contaminated with nitrogenous organic matter, ammoniacal salts, and chlorides, the presence of the latter in any quantity in surface waters at places not in the neighbourhood of the sea being an almost certain indicator of sewage. Of the conservancy systems, three of the most important varieties were—(1) The employment of tubs or pails with or without disinfectants and deodorisers; (2) ash closets; (3) dry-earth closets. In these the fæces were retained, and it was advocated that they would be extremely valuable as manures, especially from the latter. It was found, however, that the earth, after having been used three times in the dry-earth closets, did not contain more nitrogenous matter than a rich garden mould, viz., 0.446 per cent., and consequently its value as a manure was so small that it would only pay for carriage to a very short distance. Dr. Voelcker had estimated it to be worth about 7s. 6d. per ton. This arises from the fact that the total amount of nitrogen excreted in the fæcal matter is not more than one-fifth that in the urine, the former only containing 1.5 per cent of nitrogen. In Paris much of the excreta are collected and sent to Bondy, and there converted into a manure called "poudrette;" this costs the city annually a large sum, although the company who manufacture the manure make a profit. The system of pails or tubs, especially with the use of deodorisers, was essentially bad, as in the latter case the refuse matter might possibly be kept in houses some time, and deodorising was not the same as disinfecting. Numerous processes have been proposed for the precipitation of sewage. These remove the suspended matters more or less completely, deodorise the liquid, and precipitate a portion of the phosphates; but they are ineffectual, as they only partially remove the ammonia and the organic matter which is in solution, or do not do so at all. The clear liquid, therefore, is not in a fit state to be poured into the streams; moreover, the precipitate has comparatively little value as a manure. Of the method of employing sewage for irrigation, that of upward filtration was found to be useless; for, although the solid matters were removed, no oxidation took place, and the effluent water was, consequently, quite unfit to be allowed to flow into our streams. With intermittent downward filtration the case was quite different. This system was applied to the sewage of Merthyr Tydvil, a town of 50,000 inhabitants. Here, the sewage was passed on to a planted filter of 20 acres, and it was found that the effluent water contained the same amount of nitrogen as it did before it passed through the soil; but it went in as ammonia, and came out as nitrates and nitrites, being completely oxidised by its passage through the soil. In the case where the sewage is simply passed over the surface of the soil, where the plant growth alone acts, and not the oxidising action of a porous soil, the effluent water is always very impure. In order to purify sewage, therefore, it must be passed through the soil, and not merely over it. The lecturer stated that experiments had been made during two years on irrigation land consisting of 121 acres, to ascertain how much of the nitrogen was retained by the plants. In this land about 25 tons of nitrogen per annum pass in as sewage, of which 10 per cent. are lost in the effluent water as nitrates and nitrites, and 40 per cent. were recovered in the crops during the first year. The latter number was probably too high for the average, the second year giving much less.

Dr. Gilbert, who occupied the chair, said:—He quite agreed with the lecturer that all the conservancy methods hitherto proposed had failed, and no precipitation process had given a manure worth carrying beyond a very small distance. As we have to use water to cleanse our dwellings so as to get rid of all refuse matter, the best way was to send it into the sea, if near enough; and, if not, to adopt the method of intermittent irrigation, with or without previous

treatment. The results alluded to by the lecturer, as obtained from two years' experiments on land consisting of 121 acres, must not be relied on as an average; on a large scale, for a period of several years, the amount assimilated would probably be found to be much smaller.

Dr. Frankland said he agreed with Dr. Corfield as to the comparatively small value of the manures obtained by the conservancy systems, and he thought that the proportion of nitrogen in the solid and liquid excremental matter was rather under than over-stated; he should himself be inclined to say that it was six or seven times as great in the latter as in the former. One point interested him very much, namely, that the passage of the sewage through the soil purified it to a far greater extent than the plants growing in the land. He believed that this was the most effective method of treating sewage; although at Norwood, where the soil is stiff and not underdrained, the state of the effluent water was quite satisfactory even in winter.

Dr. Voelcker believed that sewage could never be made a profitable thing, and so long as that was the main thing looked to they would never arrive at a solution of the question. With regard to the utilisation of the sewage at Bondy, they profitably extracted ammonia by distillation from the liquid containing 2 per 1,000, and, although the whole sewage was not treated in this manner, several thousand tons of sulphate of ammonia were annually produced from it. The solid was mixed with charred peat and burnt gypsum to form poudrette, but the peat actually contained more nitrogenous matter than the solid faecal matter did. He also pointed out that the employment of large quantities of liquid for experiments on sewage was likely to give rise to errors, from the want of uniformity in the composition of different portions of the liquid.

Mr. Hope called attention to the fact that, in the application of Heisch's test to the effluent water, it was found that the organisms were produced when phosphoric acid was present; he thought, therefore, that was what we should search for to ascertain the purity of the water. Land at Crewe, consisting of stiff clay, was converted into a very fair filter-bed by paring off and burning the soil to the depth of 6 inches, and then ploughing it up to the depth of 3 feet by steam. It was then laid with drains at the distance of 4 feet apart.

Dr. Gilbert said that rapidly-growing crops assimilated much of the nitrogen, but in the winter-time comparatively little was taken up. Where dry manure was applied to land on which Wheat had been grown for twenty-one years successively, it was found that not more than one-third was recovered in the crop, but with Barley, where it was not exposed to the winter rains, one-third was got back.

The Best Way to Reduce Bones.—I shall be grateful for information concerning the most practicable method of pulverising bones.—J. CROUSE. To this question, Prof. S. W. Johnson has published the following answer in the *Tribune*:—"If you have ground bones, make them up into a compact heap with twice their bulk of coal-ashes, muck, sawdust, loam, or even sand; moisten the whole thoroughly with water and cover the heap with a few inches of earth. In warm weather, the bones will begin to heat in a few days, and, usually, in a week or two the bones will be reduced to a mouldy mass, that they may be rubbed to power in the hand. The exterior of the heap, for a few inches of depth, may not ferment as thoroughly. If needful, the heap may be opened, turned, moistened again, and set into a second fermentation. The larger the heap, the finer the bone, and the warmer the weather, the more rapidly will the fermentation go on. The above process will not only reduce coarsely-crushed bones to a state suitable for distribution, but is an excellent way to treat bone-dust just before application, rendering it more active. With coarser bones more time will be needful, while opening the top of the heap at various points and pouring in stale urine or dung-heap liquor will expedite the process. The Russian method of reducing entire bones with potash, or, what amounts to the same thing, with wood-ashes and lime, is as follows:—To 4,000 lbs. of bone take 4,000 lbs. of wood-ashes, 600 lbs. of fresh burned lime, 4,500 lbs. of water. First slake the lime to a powder, mix it with the ashes, and placing a layer of bones in a wooden vessel—a pit in the ground lined with boards or stone slabs—cover them with the mixture, lay down more bones and cover and repeat this until half the bones, or 2,000 lbs., are interstratified with the ashes and lime, then pour on 3,600 lbs. of water and let stand. From time to time add water to keep the mass moist. So soon as the bones have softened so that they can be crushed between the fingers to a soft soap-like mass, take the other 2,000 lbs. of bone and stratify them in another vessel or pit with the contents of the first. When the whole is soft, shovel it out to dry, and finally mix with dry muck or loam (4,000 lbs.), or enough to make it handle well."

SOCIETIES AND EXHIBITIONS

ROYAL HORTICULTURAL SOCIETY.

JUNE 17TH.

THIS meeting was less interesting than some of its predecessors. Gilbert, of Burghley, exhibited a new Melon, named Lady Isabella C. and a new seedling Grape, named Gilbert's Russian Emperor. Melon is a medium-sized oblong fruit with white flesh, and was tasted it at Burghley, a few days ago, its flavour was excellent. Grapes shown were cut from a weakly pot Vine and were, therefore, so good as they otherwise would have been; but when well-developed clusters are cut from established Vines, this Grape will, doubtless, found deserving of a place in the most select collections; the bunch tapering, the berries of a jet-black colour, and oblate in form. Messrs. J. & C. Lee sent a plant of Brown's Wonder Strawberry, taken up from the open border, to show its prolific character. I remember seeing this Strawberry in Yorkshire a year or two ago, and considered it to be an excellent variety. Mr. Douglas, of Loxley, sent Bloxham Hall Melon, a scarlet-fleshed kind, which was also shown by Mr. E. Bennet, of Hatfield. Messrs. Carter & Co. furnished Maclean Little Gem Pea for comparison with Carter's Extra Early Premium Gem. The latter being found to be, in every way, more prolific than Maclean Gem. Among flowering plants, perhaps the most interesting were Lilies, staged by Mr. Barr, Mr. G. F. Wilson, and the Rev. G. Keble. Messrs. Veitch & Son also exhibited *L. purpureum*, a creamy-white kind spotted with purplish-crimson. The other kinds were principally forms of the Martagon Lily, *L. Thunbergianum*, *L. dahuricum*, and a few other summer-blooming sorts; the kind shown by Mr. Wilson, however, appeared to be an undetermined species, with yellowish flowers. Mr. Dean, of Ealing, staged a collection of Pentstemons and Antirrhinums, and, considering the freedom with which such plants grow on dry banks or in out-of-the-way borders, they deserve more general culture than they receive. From Mr. Noble, of Sunningdale, came a nice batch of the deep rosy-flowered *Spiraea palmata*, which is one of the best of the Meadow Sweets for pot culture; it does not, however, force so freely as *S. japonica*. Messrs. Cripps and Sons contributed two varieties of hybrid Clematis, the best being *Delicata*, a semi-double variety of a lilac colour, and having fresh green foliage. Mr. Pestridge, of Brentford, exhibited a nice collection of tricolor and bronze zonal Pelargoniums in good condition; and Messrs. Downie, Laird, and Laing, Forest Hill, sent a pretty silver tricolor, named Mrs. Downie. Mr. Bull had a pretty *Pseudea* (*Hantleya*) *albo-sanguinea*, the sepals and petals of which are of pearly whiteness, and the lip deep crimson at the base, with a rosy apex. Mrs. Williams, 30, Hazlewood Crescent, Westbourne Park, showed some tastefully-modelled artificial Roses, their resemblance to the natural specimens being heightened by their being perfumed with otto of roses.

First-class Certificates were awarded to the following novelties:—

Imperial Dwarf Carnation (Veitch).—A dwarf and compact-habited scarlet self, well adapted for forcing and for furnishing cut flowers.
Lobelia Duchess of Edinburgh (Lidgard).—This is a profuse-flowering white variety, of a compact habit, and one which deserves to become popular.
Coleus Duchess of Edinburgh (Chitty).—A finely-coloured form, the leaves of which are of a rich crimson-maroon or purple margined with sulphur or apple green.

The People's Garden.—Last Saturday, the Marchioness of Lorne distributed the prizes to the successful exhibitors at a flower show which was held on that day in the People's Garden, Old Oak Common, Willesden. The Princess, and others belonging to the Royal party, made a tour of the garden, and then inspected the flowers offered for exhibition, which were staged in a tent. Amongst the exhibits were some very fine Geraniums, a great many Ferns, Roses, and other plants, besides a small quantity of fruit and vegetables. It may be as well to state that the People's Garden consists of an estate of about 50 acres, and belongs to a company who work it for their mutual advantage on the club principle. The chairman said it was generally supposed that the members were composed only of working men, but that was a mistake. The object of the club was to break down class differences, and to place every man upon the same footing, and her Royal Highness's visit that day was the crowning point of their effort. The garden is tastefully laid out, and the situation is both picturesque and convenient. Two bands were present, and the afternoon and evening were spent pleasantly and rationally.

OBITUARY.

MR. MARKHAM NESFIELD.

WE deeply regret to announce the death of Mr. A. Markham Nesfield, son of Mr. Nesfield, the distinguished painter and landscape gardener, and well-known to many of our readers. He was riding from his house, Dorset Square, in the direction of the Regent's Park, and when near the Hanover Gate his horse ran away, carrying him in the direction of St. John's Wood; on entering the St. John's Wood Road he was thrown, and almost instantaneously, the horse kicking him in the head. He had for the past ten years or so carried on the practice of landscape gardening, succeeding to his father's business, and was in the front rank of his profession. He was only in his thirty-third year.
